f) a controller receiving said electrical flow indicia and selectively operating said winch motor such that said electrical flow indicia remains within a selected operating range.

2. The mechanism to tap an electrical source according to claim **1**, wherein said selected operating range is established by an operator.

3. The mechanism to tap an electrical source according to claim **2**, further including a warning light activated when said electrical flow indicia is non-zero.

4. The mechanism to tap an electrical source according to claim **1**,

a) further including a lightning sensor generating a lightning presence indicia indicative of lightning within a prescribed range, said presence indicia being communicated to said controller; and,

b) wherein said control mechanism, in response to said lightning presence indicia, operates said winch motor to withdraw substantially all of said conductive line onto said spool.

5. The mechanism to tap an electrical source according to claim **4**, wherein said prescribed range is established by an operator.

6. The mechanism to tap an electrical source according to claim **1**, further including an electrical collection enhancement lead in electrical contact with a first end of said conductive material, said electrical collection enhancement lead configured to attract static electricity.

7. The mechanism to tap an electrical source according to claim **6**, wherein said electrical collection enhancement lead is positioned proximate to said lighter than air balloon.

8. The mechanism to tap an electrical source according to claim **7**, wherein said electrical collection enhancement lead includes at least two pointed electrical conductors.

9. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said conductive line from said winch motor.

10. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said base unit from ground.

11. A mechanism comprising:

a) an airborne aircraft having a conductive line secured to a winch capable of extending or withdrawing said conductive line from a spool, when said airborne aircraft is aloft, said conductive line collecting electricity from the atmosphere;

b) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load such that collected electricity from said conductive line powers said load;

c) an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor; and,

d) a controller receiving said electrical flow indicia adjusting an altitude of said airborne aircraft via said winch such that said electrical flow indicia remains within a selected operating range.

12. The mechanism to tap an electrical source according to claim **11**,

a) further including a lightning sensor communicating with said controller; and,

b) wherein said controller, in response to selected signals from said lightning sensor withdraws substantially all of said conductive line.

13. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon suspended in the atmosphere;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive line suspended by said balloon, a portion of said conductive line collecting electricity from the atmosphere, said winch motor capable of adjusting an altitude of said lighter than air balloon by selectively extending or withdrawing said conductive line from said spool;

c) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load being powered by said collected electricity from said conductive line;

d) a sensor array having,

1) an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor, and,

2) a lightning sensor monitoring existence of proximate lightning; and,

e) a controller responsive to said electrical flow indicia from said sensor array to selectively operate said winch motor.

14. The mechanism to tap an electrical source according to claim **13**,

a) further including a warning light; and,

b) wherein said controller activates said warning light when said electrical flow in said conductor is non-zero.

15. The mechanism to tap an electrical source according to claim **14**, further including an electrical collection enhancement lead in electrical contact with said conductive material, said electrical collection enhancement lead configured to attract static electricity and positioned proximate to said lighter than air balloon.

(57) **ABSTRACT**

A dynamic electrical converter system configured to receive a variable voltage input which is then converted to a proper electrical configuration for a load. The converter assembly utilized multiple converters, each of which is configured to accept a unique range of voltages and from these voltages creating the desired electrical output configuration. A monitor checks the incoming voltage and by controlling switches going to each of the converters, selectively closes the circuit to the appropriate converter; thereby, routing the incoming voltage to the converter capable of addressing the incoming voltage.

DYNAMIC ELECTRICAL CONVERTER SYSTEM

This is a continuation in part of U.S. patent application Ser. No. 12/218,297, filed on Jul. 14, 2008 now U.S. Pat. No. 7,855,476, and entitled, "Atmospheric Electrical Generator".

BACKGROUND OF THE INVENTION

This invention relates to the production of electrical energy and more particularly to the a conversion system for variable electrical voltages.

Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metalic base unit.

The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

This preset range is established either in the base programming of the controller or is established by an operator of the system.

As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

Another aspect of the invention relates to the electrical system which accepts the fluctuating atmospheric charge and changes it into an acceptable configuration for either the desired load or for the existing power grid.

Power grids in the United States operate with a frequency of 60 hertz in an alternating current arrangement. While this basic configuration seems to be universally accepted, the voltage within the grid varies dramatically, such as 15 kv, 34 kv, 69 kv, and even 112 kv.

Each atmospheric generator is placed proximate to or within easy access to a specific grid; this establishes the required electrical output configuration (i.e. that which is accepted by the power grid). As example, one of the atmospheric electrical collector units as described above collects the atmospheric electrical power as direct current and then supplies the appropriate power grid a specific flow (as example, AC, 60 hertz, at 69 kv).

The difficulty lies the fact that the DC current being garnered from the atmosphere varies depending on the actual agitation being generated in the atmosphere. This means that the source of DC current is fluctuating.

The present invention uses a monitoring system which checks the input DC voltage. Depending on the actual voltage being received, the appropriate converter is connected to the input DC voltage so that the desired output is obtained.

As example, suppose the DC input voltage is 1500 volts, the monitoring system, sensing this input, closes the switch connecting the DC voltage to a converter which accepts DC voltage in the range of 1000-2000 volts which then delivers an AC, 60 hertz 69 kv signal to the power grid. If the DC input voltage increases to 2100 volts, then the monitoring system opens the switch to the first converter (1000-2000 volts) and closes the switch to a second converter (such as 2000-4000 volts) to deliver the desired output of AC (60 hertz, 69 kv) for the power grid.

In this manner, regardless of the fluctuating input DC voltage, the electrical grid is supplied with a fully configured electrical input conforming to the needs of that specific electrical grid.

Another aspect of the present invention is the use of a tower or permanent structure instead of an aircraft. In this embodiment, the building or tower is electrically isolated from the ground and a rod (similar to a lightning rod) is extended into the atmosphere. The rod collects the atmospheric charge which is conveyed via an electrical conduit (ideally insulated) where the collected DC charge is reconfigured to meets the need of the locale.

In this context, for one embodiment of the invention, a tower is placed onto the top of a building. The tower is electrically isolated from the building using such mechanisms well known to those of ordinary skill in the art such as rubber mats. A rod ideally extends from the top of the tower to facilitate the collection of the DC electrical energy.

A converter mechanism such as described above, is connected to the tower to flow the DC electricity to a converter which modifies the DC current for the specific application. In one application, the DC current is converted to the electrical needs of the building, thereby providing at least some of the electrical requirements of the building itself.

As noted earlier, the dynamic converter system of the present invention allows a power generator to address a variable voltage in an efficient manner. This makes the dynamic converter system ideal for a variety of alternative energy sources such as the above described atmospheric electrical generator and other alternative energy sources such as wind and wave powered systems. In these systems, the energy being generated must be converted to a proper electrical configuration for a identified load. This may be a particular motor or connection to the power grid which act as a load to the power generating mechanism.

For these energy generating systems, the converter assembly of this invention utilizes multiple converters. Each converter is configured to accept a unique range of voltages and from these voltages, create the desired electrical configuration. By using multiple converters, a full range is available, from a minimum voltage input to a maximum voltage input.

As example, suppose the output voltage needs to be 55 kv AC, but the input voltage usually ranges from 20 kv DC to 100 kv DC. By using four different converts, this 80 kv DC range is broken into:

1) converter A accepting 20 kv DC to 40 kv DC and converting it to 55 kv AC;

2) converter B accepting 40 kv DC to 60 kv DC and converting it to 55 kv AC;

3) converter C accepting 60 kv DC to 80 kv DC and converting it to 55 kv AC; and,

4) converter A accepting 80 kv DC to 100 kv DC and converting it to 55 kv AC.

Those of ordinary skill in the art readily recognize a variety of other arrangement.

A monitor checks the incoming voltage recognizes this voltage as being addressed by a particular converter, and, by controlling switches going to each of the converters directs the input voltage appropriately. Carrying on with the above example, assume the monitor determines that the incoming voltage is 56 kv DC, then converter B is activated by selectively closing the switch associated with converter B and keeping the switches for the other converters open.

In this manner, only the appropriate converter is used for whatever the incoming voltage is.

For the situation of wind power, this permits the wind power generator to operate even in "light" winds and "heavy" winds when the amount of electricity being generated varies significantly from the desired levels. With the increased operating capability, the wind power generator is able to provide a much larger overall energy flow.

The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

FIG. **1** diagrams the preferred embodiment of the invention.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

FIG. **9** diagrams the electrical converter system being employed on a stationary structure and the dynamic converter system.

DRAWINGS IN DETAIL

FIG. **1** diagrams the preferred embodiment of the invention.

Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metalic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

The electrical current through conductor **6** is measured using sensor **8**.

In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mar. 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

Conductive lead **82** is positioned proximate to balloon **80**.

In FIG. **4**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

FIG. **9** diagrams the electrical converter system being employed on a stationary structure and the dynamic converter system.

This illustration uses a structure for the collection of the atmospheric energy. The circuit described in this illustration is not to be construed only to this energy collection mechanism, but, is adapted work with any number of energy collection/generation mechanisms, including, but not limited to: solar collectors; wind power generators; wave motion power generators; and, the atmospheric energy collection mechanisms described herein.

The structure of this embodiment is tower **90** which is electrically isolated from the ground via insulators **91**A and **91**B. In this manner, any atmospheric energy collected is maintained within tower **90**.

Conduit **90** contains antenna **93** which is moved up/down as illustrated by arrow **95** by motor **94**. Motor **94** is controlled by monitor/computer **102** based upon the electrical energy being collected by antenna **93** and communicated via insulated conductor **96**, monitored by sensor **101**.

The collected energy is communicated to a bank of switches (**97**A, **97**B, **97**C, through **97**N, N being any number of switches). In this manner, each switch receives the electrical energy being gathered by antenna **93**. As noted earlier, this electrical energy varies depending on the ambient conditions.

Each switch addresses a single converter. As illustrated, switch **97**A, when closed, communicates the electrical energy to converter **98**A; switch **97**B to converter **98**B; switch **97**C to converter **98**C; and so on until switch **97**N to converter **98**N.

Each converter is designed to accept a range of electrical input and generate a uniform electrical configuration to load **100**A.

Monitor/computer **102** monitors the varying electrical input from antenna **93** via sensor **101**. Based upon the electrical input, monitor/computer **102** closes a selected one of the switches (and opens all of the rest) so that the voltage being received is directed to the converter designed to handle that voltage.

In some situations, the voltage is so large that (or during emergency) that emergency switch **99** must be closed to direct the voltage to an artificial load or ground either during the switching of switches **97**A-**97**N or to "shut down" the system for repairs/maintenance or if lightning is sensed within a "dangerous" range of tower **90**.

In this context, an artificial load is anything that expends the incoming energy, such as lifting a weight to let it fall once switch **99** is opened, or pumping water out of and then into the same reservoir.

It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. An electrical converter system comprising:

a static electricity collector having a conductor that collects static electricity from the atmosphere and outputs a collected energy, the conductor having a height from a stationary structure, the height being adjustable by a motor coupled with the stationary structure;

a plurality of converters in electrical communication with the conductor, each converter configured to accept a unique range of voltages and producing a uniform electrical output;

a plurality of switches, each switch receiving an input voltage based on the collected energy from the conductor, and connected to corresponding one of said plurality of converters; and

a monitor having a sensor that measures the collected energy from the conductor, the monitor operating the motor to adjust the height of the conductor relative to the stationary structure such that the collected energy remains within a selected operating range, the sensor further identifying a level of the input voltage of each of switch to selectively close one of the plurality of switches in response to the level of the input voltage and based on the unique range of voltages.

2. The electrical converter system according to claim **1**, further comprising:

a load; and

a load switch connecting said input voltage to said load,

wherein said monitor closes, when the level of input voltage exceeds a predetermined value, said load switch prior to closing one of said plurality of switches.

3. The electrical converter system according to claim **2**, wherein said load switch routes said input voltage to ground.

4. The electrical converter system according to claim **2**, wherein said monitor closes said load switch if said input voltage exceeds the unique ranges of voltages for all of said plurality of converters.

5. The electrical converter system according to claim **2**, further comprising:

a lightning sensor generating a signal indicative of a distance to a lightning activity, said monitor closing said load switch when said signal indicative of a distance to a lightning activity is within a prescribed range.

6. The electrical converter system according to claim **2**, wherein said monitor opens said load switch after closing one of said plurality of switches.

7. The electrical converter system according to claim **1**, wherein said input voltage is direct current.

8. The electrical converter system according to claim **1**, wherein said input voltage is alternating current.

9. The electrical converter system according to claim **1**, wherein each converter of the plurality of converters converts direct current to alternating current.

10. An electrical system comprising:

a static electricity collector having a conductor that collects static electricity from the atmosphere and outputs a collected energy, the conductor having a height from a stationary structure, the height being adjustable by a motor coupled with the stationary structure;

a power generating mechanism in electrical contact with the conductor and generating a variable voltage from the static electricity;

a power grid electrically connected to consumers of electricity, said power grid operating at a uniform electrical configuration; and,

a conversion system comprising:

- a plurality of converters, each converter configured to accept a unique range of voltages and producing said uniform electrical configuration to said power grid;
- a plurality of switches, each switch receiving the variable voltage and connected to corresponding one of said plurality of converters; and

a monitor comprising a sensor that measures the collected energy from the conductor, the monitor operating the motor to adjust the height of the conductor relative to the stationary structure such that the collected energy remains within a selected operating range, the sensor further identifying a level of the variable voltage, and, in response to said level of the variable voltage, selectively closing one of said plurality of switches.

11. The electrical system according to claim **10**, wherein said variable voltage is direct current, the direct current being converted to alternating current by the corresponding one of said plurality of converters.

12. The electrical system according to claim **10**, wherein said power generating mechanism is reactive to atmospheric voltage.

13. The electrical system according to claim **12**, further comprising:

a lighting sensor generating a signal indicative of a distance to a lightning activity said monitor closing an artificial load switch when said signal indicative of a distance to a lightning activity is within a prescribed range.

14. The electrical converter system according to claim **10**, wherein said variable voltage is alternating current.

15. The electrical system according to claim **14**, wherein said power generating mechanism is reactive to wind power.

16. An electrical converter system receiving a variable voltage input and connected to a load requiring a set electrical configuration, said system comprising:

a static electricity collector having a conductor that collects static electricity from the atmosphere and outputs a collected energy, the conductor having a height from a stationary structure, the height being adjustable by a motor coupled with the stationary structure;

a converter assembly in electrical communication with the conductor comprising:

a plurality of converters, each converter configured to accept a unique range of voltages from the collected energy and producing the set electrical configuration, and,

a plurality of switches, each switch receiving the variable voltage input and connected to corresponding one of said plurality of converters;

a sensor that measures the collected energy from the conductor, the sensor further identifying a level of the variable voltage input; and

a monitor that operates the motor to adjust the height of the conductor relative to the stationary structure such that the collected energy remains within a selected operating range, the monitor further selectively closing, in response to said level of the input voltage, one of said plurality of switches.

17. The system according to claim **16**, further comprising:

a load; and

a load switch connecting said variable voltage input to said load, said monitor closing said load switch prior to closing one of said plurality of switches.

18. The system according to claim **17**, wherein said load switch routes said variable voltage input to ground.

19. The system according to claim **17**, further comprising:

a lighting sensor generating a signal indicative of a distance to a lightning activity said monitor closing said load switch when said signal indicative of a distance to a lightning activity is within a prescribed range.

20. The system according to claim **16**, wherein said monitor closes said load switch if said variable voltage input exceeds the unique range of voltages for all of said plurality of converters.

(57) **ABSTRACT**

An antenna for the collection of atmospheric static electricity in which an electrically conductive hub is suspended from a balloon or blimp via a tether. The hub is either solid or uses a spoke/arm arrangement. A number of rods extend from the hub enhance the collection of atmospheric static electricity. The collected atmospheric electricity is conducted from the rods to an electrical connection where the electricity is conducted to earth via a conductive line.

ATMOSPHERIC STATIC ELECTRICITY COLLECTOR

CROSS REFERENCE TO RELATED APPLICATIONS

This application is a continuation and claims the benefit of priority under 35 U.S.C. §120 of U.S. patent application Ser. No. 12/321,306, filed Jan. 16, 2009, entitled "Atmospheric Static Electricity Collector", now U.S. Pat. No. 8,102,082, which is a continuation-in-part of U.S. patent application Ser. No. 12/218,297, filed Jul. 14, 2008, entitled "Atmospheric Electrical Generator", now U.S. Pat. No. 7,855,476, which the disclosures of the priority applications are incorporated by reference herein.

BACKGROUND OF THE INVENTION

This invention relates to the production of electrical energy and more particularly to the collection of static electricity from the atmosphere.

Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metallic base unit.

The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

This preset range is established either in the base programming of the controller or is established by an operator of the system.

As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

An aspect of the present invention is the use of an antenna which are used to collect the atmospheric static electricity. The antenna is shaped as a hub which is suspended from the blimp/balloon. The hub is ideally spoked shaped although an alternative embodiment uses a solid hub.

A number of rods extend from the hub so as collect atmospheric static electricity. These rods are ideally rounded at the ends to enhance the attraction of the atmospheric static electricity.

The collected atmospheric electricity is conducted from the rods to an electrical connection on the hub where the electricity is conducted to a power plant on earth such as described above.

The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

FIG. **1** diagrams the preferred embodiment of the invention.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

FIGS. **9**A and **9**B are side views and top views of an embodiment of the antenna used to collected atmospheric electricity.

FIG. **10** is a top view of an alternative embodiment of the antenna of this invention.

FIG. **11** is a side view of yet another alternative embodiment of the antenna used to collect atmospheric electricity.

FIG. **12** is the preferred embodiment of the antenna of this invention.

DRAWINGS IN DETAIL

FIG. **1** diagrams the preferred embodiment of the invention.

Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metallic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

The electrical current through conductor **6** is measured using sensor **8**.

In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

In the preferred embodiment, the “safe” distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to “safe” distance.

There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled “Lightning Detection” issued to Makela, et al. on Mar. 21, 2006; U.S. Pat. No. 6,829,911, entitled “Lightning Detection and Prediction Alarm Device” issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled “Detection of Lightning” issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled “Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

Conductive lead **82** is positioned proximate to balloon **80**.

In FIG. **8**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

FIGS. **9**A and **9**B are side views and top views of an embodiment of the antenna used to collected atmospheric electricity.

Blimp **90** supports antenna **92** via tether **91** which is attached to antenna **92** by connection **94**. In this embodiment, antenna **92** is made of electrically conductive material and is ideally light in weight to lessen the payload requirements on blimp **90**.

Encircling antenna **92** and extending therefrom are rods **93** which are rounded at their distal ends so as to enhance attraction of the atmospheric static electricity. The static electricity is communicated to connection **96** and then to electrical line **95** which communicates the electricity to the ground based station (not shown) as described above.

FIG. **10** is a top view of an alternative embodiment of the antenna of this invention,

In this embodiment of the antenna a central hub **101** has the blimp connection **104** (capable of receiving the tether to the blimp) secured thereto. In this illustration, four arms **102**A, **102**B, **102**C, and **102**D extend from hub **101**. Hub **101**, and arms **102**A, **102**B, **102**C, and **102**D are all electrically conductive in this embodiment.

At the end of each arm are rods **103** which are used to enhance the collection of the atmospheric static electricity.

Although this embodiment illustrates four arms, the invention is not intended to be limited to four arms, rather, any number of arms may be used and the number of rods extending from the distal ends of the arms also varies.

FIG. **11** is a side view of yet another alternative embodiment of the antenna used to collect atmospheric electricity.

In this embodiment, several tethers **112**A, **112**B, and **112**C, are used to secure the antenna **113** to the blimp **111**. This arrangement of several tethers provides heightened stability of the antenna by reducing the affects wind will have on the antenna.

FIG. **12** is the preferred embodiment of the antenna of this invention.

In this embodiment of the antenna, arms **122**A, **122**B, and **122**C extend from a central hum and are electrically connected to rim **124**. Tether connectors **123**A, **123**B, and **123**C, are used to secure the antenna to the blimp or balloon.

Rods **125** extend from rim **124** to increase the collection of the static charges in the atmosphere.

It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. A system for collection of atmospheric static electricity comprising:

a balloon;

a hub that is electrically conductive and connected to the balloon by a tether, the hub having:

two or more arms that are electrically conductive, a first end of each of the two or more arms electrically connected to the hub; and

a plurality of rods, a first end of each of the rods being electrically connected to a second end of at least one of the two or more arms;

a base unit having a spool of conductive line on a winch motor, one end of the conductive line secured to the hub, a portion of the conductive line and the hub collecting electricity in the atmosphere, the winch motor selectively extending or withdrawing the conductive line from the spool;

a conductor having a first end electrically connected to the conductive line and a second end electrically connected to a load being powered by collected electricity from the conductive line;

an electrical flow sensor monitoring electrical flow through the conductor and generating an electrical flow indicia indicative of the electrical flow in the conductor; and

a controller to operate the winch motor to maintain the electrical flow indicia within a selected operating range.

2. The system according to claim **1**, wherein each of the plurality of rods has a rounded second end.

3. The system according to claim **1**, wherein at least two rods are attached to the second end of each of the two or more arms.

4. The system according to claim **1**, further comprising an electrically conductive rim connected to a second end of the two or more arms.

5. The system according to claim **4**, wherein at least a portion of the two or more electrically conductive arms are connected substantially at right angles to an exterior of the electrically conductive rim.

6. A system for collection of atmospheric static electricity comprising:

two or more arms that are electrically conductive;

a plurality of rods, each of the plurality of rods being electrically connected to at least one of the two or more arms; and

a balloon tether connected between a balloon and the two or more arms;

a base unit having a spool of conductive line on a winch motor, one end of the conductive line secured to the two or more arms, a portion of the conductive line and the two or more arms collecting electricity in the atmosphere, the winch motor selectively extending or withdrawing the conductive line from the spool;

a conductor having a first end electrically connected to the conductive line and a second end electrically connected to a load being powered by collected electricity from the conductive line;

an electrical flow sensor monitoring electrical flow through the conductor and generating an electrical flow indicia indicative of the electrical flow in the conductor; and

a controller to operate the winch motor to maintain the electrical flow indicia within a selected operating range.

7. The system according to claim **6**, wherein each of the plurality of rods has a rounded end distal from the electrically conductive arm.

8. The system according to claim **7**, further including a balloon tether connection secured to the first end of the two or more arms.

9. The system according to claim **8**, further including an electrical connection secured to the first end of each of the two or more arms.

10. The system according to claim **9**, wherein the at least two rods attached to the two or more arms includes three or more rods.

11. The system according to claim **9**, further including an electrically conductive rim connected to a second end of the two or more arms.

12. The system according to claim **11**, wherein the plurality of arms are electrically connected to the electrically conductive rim.

13. The system according to claim **12**, wherein at least a portion of the plurality of rods are connected to an exterior of the electrically conductive rim substantially at right angles thereto.

14. A system for the collection of atmospheric static electricity comprising:

an electrically conductive body;

a balloon tether connected to a first side of the electrically conductive body and to a balloon; and

an electrical connection connected to a second side of the electrically conductive body;

a base unit having a spool of conductive line on a winch motor, one end of the conductive line secured to the electrical connection, a portion of the conductive line and the electrically conductive body collecting electricity in the atmosphere, the winch motor selectively extending or withdrawing the conductive line from the spool;

a conductor having a first end electrically connected to the conductive line and a second end electrically connected to a load being powered by collected electricity from the conductive line;

an electrical flow sensor monitoring electrical flow through the conductor and generating an electrical flow indicia indicative of the electrical flow in the conductor; and

a controller receiving the electrical flow indicia and selectively operating the winch motor such that the electrical flow indicia remains within a selected operating range.

15. The system according to claim **14**, wherein the electrically conductive body comprises:

an electrically conductive hub;

at least three electrically conductive arms, each of the arms connected at a first end to the hub; and

an electrically conductive rim connected to the second end of each of the at least three arms.

16. The system according to claim **15**, further comprising a plurality of electrically conductive rods, a first end of each of the rods connected to the rim and extending therefrom substantially at rights angles thereto.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more

around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected

to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the support structure;

providing a load with an electrical connection to the at least one collection device to passively draw current; and

powering a fuel cell between the support structure and the load, the powering performed with energy collected from the at least one collection device.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a diode electrically connected between the at least one collection device and the support structure.

9. The system of claim **8**, wherein the collection device comprises a diode.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising:

a switch connected in series between the at least one collection device and the load; and

a capacitor connected in parallel with the switch and the load.

15. The system of claim **14**, wherein the switch comprises an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

16. The system of claim **15**, further comprising a transformer connected between the interrupter and the load.

17. The system of claim **8**, further comprising:

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the means for suspending;

means for passively inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

21. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a switch connected in series between the at least one collection device and the load, the switch comprising an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

22. The system of claim **21**, further comprising a transformer connected between the interrupter and the load.

23. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure, the collection device configured to passively draw current;

a load electrically connected to the at least one collection device;

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

24. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a fuel cell between the support structure and the load.

25. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

TECHNICAL FIELD

[0001] The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

[0002] The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

[0003] In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

[0004] Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

[0005] Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

[0006] While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

[0007] Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

[0008] Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

[0009] Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

[0011] FIG. **1** is a circuit diagram of a weather energy circuit.

[0012] FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

[0013] FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

[0014] FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

[0015] FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

[0016] FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

[0017] FIG. **2**E is a side view of a support structure for an energy collection fiber.

[0018] FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

[0019] FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

[0020] FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

[0021] FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

[**0022**] FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

[**0023**] FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

[**0024**] FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

[**0025**] FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

[**0026**] FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

[**0027**] Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

[**0028**] An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

[**0029**] In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than **100** volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

[**0030**] A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

[**0031**] Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. 2A-2G using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

[**0032**] Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

[**0033**] FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

[**0034**] FIG. **2**D presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[**0035**] FIG. **2**E provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

[**0036**] FIG. **2**F presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[**0037**] FIG. **2**G provides two supports as provided in FIG. **2**F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

[**0038**] FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load.

[**0039**] Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

[**0040**] In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground.

[**0041**] The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

[**0042**] FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

[**0043**] FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

[**0044**] FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

[**0045**] FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

[**0046**] FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

[**0047**] Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

[**0048**] It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device from a plurality of support structure wires elevated above a ground level, the collection device electrically connected to the support structure wire; and

providing a load with an electrical connection to the plurality of support structure wires to draw current.

2. The method of claim 1, wherein the collection device comprises a diode.

3. The method of claim 1, wherein the collection device comprises a collection fiber.

4. The method of claim 1, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim 1, further comprising storing energy provided to the load.

6. The method of claim 5, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim 3, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. The method of claim 2, wherein the diode is elevated relative to the ground level.

9. A system of energy collection comprising:

a plurality of support structure wires elevated above ground level;

at least one collection device electrically connected to the plurality of support structure wires; and

a load electrically connected to the plurality of support structure wires.

10. The system of claim 9, wherein the collection device comprises a diode.

11. The system of claim 9, wherein the collection device comprises a collection fiber.

12. The system of claim 9, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

13. The system of claim 10, wherein the diode is elevated relative to the ground level.

14. The system of claim 11, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

15. The system of claim 9, further comprising a diode electrically connected between the at least one collection device and the plurality of support structure wires.

16. The system of claim 11, wherein the collection fiber comprises a first end and a second opposing end, and wherein the system further comprises a support structure connected to both ends of the collection fiber.

17. The system of claim 11, further comprising:

a plurality of collection fibers;

a support frame having a top side and a bottom side; and

a conducting connecting wire between the plurality of support structure wires and the support frame,

wherein one end of each of a plurality of collection fibers is connected to the top side of the support frame, and the opposing end of each of a plurality of collection fibers is connected to the bottom side of the support frame.

18. The system of claim 11, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from a single point of the support structure, wherein each end of the collection fiber is connected to an end of the multiple supports.

19. The system of claim 11, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from multiple points of the support structure, wherein each end of the collection fiber is connected to an end of the multiple supports.

20. The system of claim 18, further comprising a plurality of rigid structures wherein collection fibers are connected between a plurality of the rigid structures.

21. The system of claim 9, further comprising:

a switch connected in series between the plurality of support structure wires and the load; and

a capacitor connected in parallel with the switch and the load.

22. The system of claim 21, wherein the switch comprises an interrupter connected between the plurality of support structure wires and the load.

23. The system of claim 22, wherein the interrupter comprises one of a fluorescent tube, a neon bulb, an AC light, or a spark gap.

24. The system of claim 22, further comprising a transformer connected between the interrupter and the load.

25. The system of claim 9, further comprising:

a motor for providing power the motor connected between the plurality of support structure wires and the load; and

a generator powered by the motor.

26. The system of claim 9, wherein the load comprises a spark gap in a container of fluid, and the load is used to produce a chemical reaction.

27. The system of claim 26, wherein the fluid comprises water and the chemical reaction comprises the production of hydrogen and oxygen.

28. The system of claim 9, further comprising a fuel cell between the plurality of support structure wires and the load.

29. The system of claim 9, wherein the load comprises a fuel cell.

30. The system of claim 28, wherein the fuel cell produces hydrogen and oxygen.

31. The system of claim 28, further comprising a diode connected between the plurality of support structure wires and the fuel cell.

32. A system of collecting energy comprising:

means for suspending collection fibers, the means elevated above a ground level, the collection fibers electrically connected to the means for suspending collection fibers;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending collection fibers; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the collection fibers and the means for inducing current flow.

(57) **ABSTRACT**

A mechanism to tap an electrical source which uses an aircraft (**10**) (preferably a lighter than air balloon) tethered by a conductive line (**12**). The conductive line (**12**) is extended/withdrawn by a winch motor (**13**, **14**) to adjust the altitude of the aircraft (**10**). The conductive line (**12**) is isolated from the ground (**17**) and an electrical conductor (**6**) is connected to the conductive line and to an electrical load (**5**). In this manner, static electricity generated in the atmosphere is gathered for use.

ATMOSPHERIC ELECTRICAL GENERATOR WITH CHANGE OF STATE

[0001] This is a continuation-in-part of U.S. patent application Ser. No. 12/218,297, entitled "Atmospheric Electrical Generator", filed on Jul. 14, 2008, by Ogram.

BACKGROUND OF THE INVENTION

[0002] This invention relates to the production of electrical energy and more particularly to the production of electrical energy from the atmosphere.

[0003] Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

[0004] Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

[0005] Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

[0006] It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

[0007] While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

[0008] It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

[0009] The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0010] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

[0011] The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0012] The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

[0013] Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

[0014] The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

[0015] The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

[0016] In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

[0017] In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

[0018] A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metalic base unit.

[0019] The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

[0020] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

[0021] A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

[0022] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

[0023] The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0024] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0025] This preset range is established either in the base programming of the controller or is established by an operator of the system.

[0026] As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0027] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0028] The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWING IN BRIEF

[0029] FIG. **1** diagrams the preferred embodiment of the invention.

[0030] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0031] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0032] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0033] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0034] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0035] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0036] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

DRAWINGS IN DETAIL

[0037] FIG. **1** diagrams the preferred embodiment of the invention.

[0038] Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

[0039] Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

[0040] In this embodiment, located proximate to balloon **10**, is an electrical apparatus **11**. The electrical apparatus **11**, is either a collection enhancement mechanism which enhances the collection of static electricity or a transformer.

[0041] In the collection enhancement lead embodiment, an electrical collection enhancement lead is configured to attract the static charge and conduct the charge into the conductive line **12**.

[0042] In another embodiment, the electrical apparatus **11** is a transformer which converts the atmospheric static electricity from a direct current configuration to an alternating current configuration. An insulated conductor extends from the ground to the transformer to assist in this operation.

[0043] Those of ordinary skill in the art readily recognize a variety of DC-AC transformers such as, but not limited to: U.S. Pat. No. 7,471,528, entitled "Parallel Operating System of DC-AC Converters and Controller IC Therefor" issued to Fukumoto on Dec. 30, 2008; U.S. Pat. No. 7,499,290, entitled "Power Conversion" issued to Mazzola, et al. on Mar. 3, 2009; U.S. Pat. No. 7,531,993, entitled "Half Bridge Circuit and Method of Operating a Half Bridge Circuit" issued to Udrea et al. on May 12, 2009; U.S. Pat. No. 5,538,536, entitled "DC-AC Converter and Controller IC Therefor" issued to Fukumoto on May 26, 2009; and, U.S. Pat. No. 7,554,823, entitled "Controller IC, DC-AC Conversion Appratus, and Parallel Running System of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jun. 30, 2009; all of which are incorporated hereinto by reference.

[0044] The electricity flows, whether direct current or alternating current, using the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

[0045] Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

[0046] In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metalic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

[0047] The electrical current through conductor **6** is measured using sensor **8**.

[0048] In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

[0049] Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

[0050] The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

[0051] In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

[0052] In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

[0053] In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

[0054] There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mar. 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

[0055] In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

[0056] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0057] Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

[0058] Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

[0059] By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

[0060] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0061] Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

[0062] When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

[0063] If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0064] If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0065] In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

[0066] As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

[0067] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0068] By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0069] Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

[0070] Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

[0071] FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

[0072] Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

[0073] In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

[0074] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0075] This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

[0076] The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

[0077] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0078] This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

[0079] An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

[0080] Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

[0081] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0082] In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

[0083] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0084] Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

[0085] Conductive lead **82** is positioned proximate to balloon **80**.

[0086] In FIG. **4**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

[0087] It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon;

b) a direct current to alternating current transformer electrically connected via an electrically exposed tether to said lighter than air balloon and said base unit such that alternating current is communicated to said base unit; and,

c) a base unit having a spool of insulated conductive wire on a winch motor, one end of said insulated conductive wire electrically connected to an output of said direct current to alternating current transformer, said winch motor capable of selectively extending or withdrawing said insulated conductive wire from said spool, a second end of said insulated conductive wire electrically connected to a load.

2. The mechanism to tap an electrical source according to claim **1**, further including a controller, said controller selectively operating said winch motor based upon a voltage level in said insulated conductor wire.

3. The mechanism to tap an electrical source according to claim **2**,

a) further including an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor, said electrical flow indicia communicated to said controller; and,

b) wherein said controller operates said winch motor such that said electrical flow indicia remains within a selected operating range.

4. The mechanism to tap an electrical source according to claim **3**, wherein said conductor further includes an insulated ground wire communicating between said direct current to alternating current transform and ground.

5. The mechanism to tap an electrical source according to claim **4**,

a) further including a lightning sensor generating a lightning presence indicia indicative of lightning within a prescribed range, said presence indicia being communicated to said controller; and,

b) wherein said controller, in response to said lightning presence indicia, operates said winch motor to withdraw substantially all of said insulated conductive wire onto said spool.

6. A mechanism comprising:

a) an airborne aircraft tethered by a conductive line secured to a winch capable of extending or withdrawing said conductive line from a spool; and,

b) a direct current to alternating current transformer connected via an electrically conductive tether to said lighter than air balloon.

7. The mechanism according to claim **6**, further including a base unit selectively extending and withdrawing an insulated conductive wire to an output of said direct current to alternating current transformer.

8. The mechanism according to claim **7**, wherein a second end of said insulated conductive wire is electrically connected to an earthbound load.

9. The mechanism according to claim **8**,

a) further including a lightning sensor communicating with said base unit; and,

b) wherein said base unit, in response to selected signals from said lightning sensor withdraws substantially all of said insulated conductive wire.

10. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon;

b) a direct current to alternating current transformer, said transformer having an electrically exposed tether connected to said lighter than air balloon such that direct current from the atmosphere is communicated to said transformer;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive material secured to said transformer so that alternating current is provided to said conductive line, said winch motor capable of adjusting an altitude of said lighter than air balloon by selectively extending or withdrawing said conductive line from said spool;

c) an insulator electrically isolating said conductive line from ground; and,

d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load;

e) a sensor array having,

1) an electrical flow sensor monitoring electrical flow through said conductor, and,

2) a lightning sensor monitoring existence of proximate lightning; and,

f) a controller responsive to signals from said sensor array to selectively operate said winch motor.

11. The mechanism to tap an electrical source according to claim **10**,

a) further including a warning light; and,

b) wherein said controller activates said warning light when said electrical flow in said conductor is non-zero.

12. The mechanism to tap an electrical source according to claim **10**, further including an electrical collection enhancement lead in electrical contact with said conductive material, said electrical collection enhancement lead configured to attract static electricity and positioned proximate to said lighter than air balloon.

(57) **ABSTRACT**

An antenna for the collection of atmospheric static electricity in which an electrically conductive hub is suspended from a balloon or blimp via a tether. The hub is either solid or uses a spoke/arm arrangement. A number of rods extend from the hub enhance the collection of atmospheric static electricity. The collected atmospheric electricity is conducted from the rods to an electrical connection where the electricity is conducted to earth via a conductive line.

FIG. 12

ATMOSPHERIC STATIC ELECTRICITY COLLECTOR

BACKGROUND OF THE INVENTION

[0001] This invention relates to the production of electrical energy and more particularly to the collection of static electricity from the atmosphere.

[0002] This is a continuation in part of U.S. patent application Ser. No. 12/218,297, filed on Jul. 14, 2008, and entitled, "Atmospheric Electrical Generator".

[0003] Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

[0004] Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

[0005] Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

[0006] It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

[0007] While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

[0008] It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

[0009] The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0010] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

[0011] The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0012] The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

[0013] Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

[0014] The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

[0015] The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

[0016] In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

[0017] In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

[0018] A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metalic base unit.

[0019] The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

[0020] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

[0021] A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

[0022] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

[0023] The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0024] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0025] This preset range is established either in the base programming of the controller or is established by an operator of the system.

[0026] As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0027] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0028] An aspect of the present invention is the use of an antenna which are used to collect the atmospheric static electricity. The antenna is shaped as a hub which is suspended from the blimp/balloon. The hub is ideally spoked shaped although an alternative embodiment uses a solid hub.

[0029] A number of rods extend from the hub so as collect atmospheric static electricity These rods are ideally rounded at the ends to enhance the attraction of the atmospheric static electricity.

[0030] The collected atmospheric electricity is conducted from the rods to an electrical connection on the hub where the electricity is conducted to a power plant on earth such as described above.

[0031] The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

[0032] FIG. **1** diagrams the preferred embodiment of the invention.

[0033] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0034] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0035] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0036] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0037] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0038] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0039] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0040] FIGS. **9**A and **9**B are side views and top views of an embodiment of the antenna used to collected atmospheric electricity.

[0041] FIG. **10** is a top view of an alternative embodiment of the antenna of this invention.

[0042] FIG. **11** is a side view of yet another alternative embodiment of the antenna used to collect atmospheric electricity.

[0043] FIG. **12** is the preferred embodiment of the antenna of this invention.

DRAWINGS IN DETAIL

[0044] FIG. **1** diagrams the preferred embodiment of the invention.

[0045] Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

[0046] Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

[0047] In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **1 1** is configured to attract the static charge and conduct the charge into the conductive line **12**.

[0048] The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

[0049] Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

[0050] In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metalic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

[0051] The electrical current through conductor **6** is measured using sensor **8**.

[0052] In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

[0053] Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

[0054] The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

[0055] In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

[0056] In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

[0057] In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

[0058] There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mac. 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

[0059] In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

[0060] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0061] Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

[0062] Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

[0063] By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

[0064] FIG. 3 is a flowchart of the operation of the controller for the preferred embodiment of the invention.

[0065] Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

[0066] When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

[0067] If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0068] If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0069] In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

[0070] As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

[0071] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0072] By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0073] Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

[0074] Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

[0075] FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

[0076] Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

[0077] In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

[0078] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0079] This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

[0080] The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

[0081] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0082] This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

[0083] An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

[0084] Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

[0085] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0086] In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

[0087] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0088] Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

[0089] Conductive lead **82** is positioned proximate to balloon **80**.

[0090] In FIG. **8**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

[0091] FIGS. **9**A and **9**B are side views and top views of an embodiment of the antenna used to collected atmospheric electricity.

[0092] Blimp **90** supports antenna **92** via tether **91** which is attached to antenna **92** by connection **94**. In this embodiment, antenna **92** is made of electrically conductive material and is ideally light in weight to lessen the payload requirements on blimp **90**.

[0093] Encircling antenna **92** and extending therefrom are rods **93** which are rounded at their distal ends so as to enhance attraction of the atmospheric static electricity. The static electricity is communicated to connection **96** and then to electrical line **95** which communicates the electricity to the ground based station (not shown) as described above.

[0094] FIG. **10** is a top view of an alternative embodiment of the antenna of this invention.

[0095] In this embodiment of the antenna a central hub **101** has the blimp connection **104** (capable of receiving the tether to the blimp) secured thereto. In this illustration, four arms **102**A, **102**B, **102**C, and **102**D extend from hub **101**. Hub **101**, and arms **102**A, **102**B, **102**C, and **102**D are all electrically conductive in this embodiment.

[0096] At the end of each arm are rods **103** which are used to enhance the collection of the atmospheric static electricity.

[0097] Although this embodiment illustrates four arms, the invention is not intended to be limited to four arms, rather, any number of arms may be used and the number of rods extending from the distal ends of the arms also varies.

[0098] FIG. **11** is a side view of yet another alternative embodiment of the antenna used to collect atmospheric electricity.

[0099] In this embodiment, several tethers **112**A, **112**B, and **112**C, are used to secure the antenna **113** to the blimp **111**. This arrangement of several tethers provides heightened stability of the antenna by reducing the affects wind will have on the antenna.

[0100] FIG. **12** is the preferred embodiment of the antenna of this invention.

[0101] In this embodiment of the antenna, arms **122**A, **122**B, and **122**C extend from a central hum and are electrically connected to rim **124**. Tether connectors **123**A, **123**B, and **123**C, are used to secure the antenna to the blimp or balloon.

[0102] Rods **125** extend from rim **124** to increase the collection of the static charges in the atmosphere.

[0103] It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. An antenna for the collection of atmospheric static electricity comprising:
- a) a hub being electrically conductive and having,
  - 1) a balloon tether, and,
  - 2) an electrical connection;
- b) at least three electrically conductive arms, a first end of each of said conductive arms electrically connected to said hub; and,
- b) a plurality of rods, a first end of each of said rods being electrically connected to a second end of att least one of said at least three arms.

2. The antenna according to claim **1**, wherein each of said plurality of rods has a rounded second end.

3. The antenna according to claim **2**, wherein at least two rods are attached to the second end of each of said at least three arms.

4. The antenna according to claim **1**, further including an electrically conductive rim connected to a second end of said electrically conductive arms.

5. The antenna according to claim **4**, wherein at least a portion of said plurality of electrically conductive arms are connected substantially at right angles to an exterior of said electrically conductive rim.

6. An antenna for the collection of atmospheric static electricity comprising:
- a) a radial arrangement of at least three electrically conductive arms; and,
- b) a plurality of rods, each of said rods being electrically connected to at least one of said at least three arms.

7. The antenna according to claim **6**, wherein each of said plurality of rods has a rounded end distal from said electrically conductive arm.

8. The antenna according to claim **7**, further including a balloon tether connection secured to the first end of said at least three arms.

9. The antenna according to claim **8**, further including an electrical connection secured to the first end of said at least three arms.

10. The antenna according to claim **9**, wherein said at least two rods attached to said at least three arms is five rods.

11. The antenna according to claim **9**, further including an electrically conductive rim connected to a second end of said electrically conductive arms.

12. The antenna according to claim **11**, wherein said plurality of arms are electrically connected to said electrically conductive rim.

13. The antenna according to claim **12**, wherein at least a portion of said plurality of rods are connected to an exterior of said electrically conductive rim substantially at right angles thereto.

14. An antenna for the collection of atmospheric static electricity comprising:

a) a generally circular electrically conductive body;

b) a a balloon tether connected to a first side of said generally circular electrically conductive body; and,

c) an electrical connection connected to a second side of said generally circular electrically conductive body.

15. The antenna according to claim **14**, wherein said generally circular electrically conductive body includes:

a) an electrically conductive hub;

b) at least three electrically conductive arms, each of said arms connected at a first end to said hub; and,

c) an electrically conductive rim connected to the second end of each of said at least three arms.

16. The antenna according to claim **15**, further including a plurality of electrically conductive rods, a first end of each of said rods connected to said rim and extending therefrom substantially at rights angles thereto.

(57) ABSTRACT

A transducer converts energy coming from an energy source into an electrical signal for storage as electrical energy on a first storage element. A switch is selectively actuated to pass electrical energy from the first storage element to a second storage element. The selective actuation of the switch is driven by sensing electrical energy stored in the second storage element. The switch is closed when electrical energy in the second storage element is sensed to fall below a first threshold. The switch is opened when electrical energy in the second storage element is sensed to rise above a second threshold.

SYSTEM AND METHOD FOR EFFICIENTLY HARVESTING ENVIRONMENTAL ENERGY

PRIORITY CLAIM

[0001] This application claims priority from Italian Application for Patent No. TO2011A000379 filed Apr. 29, 2011, the disclosure of which is hereby incorporated by reference.

TECHNICAL FIELD

[0002] The present invention relates to a system and to a method for efficiently harvesting environmental energy.

BACKGROUND

[0003] As is known, systems for harvesting energy (also known as "energy harvesting" or "energy scavenging" systems) from intermittent environmental energy sources, have aroused and continue to arouse considerable interest in a wide range of technological fields. Typically, energy harvesting systems are designed to harvest, store, and transfer energy generated by mechanical sources to a generic load of an electrical type.

[0004] One of the main energy sources that can be used for harvesting mechanical energy and converting it into electrical energy is constituted by piezoelectric or electromagnetic devices. Low-frequency vibrations, such as for example mechanical vibrations of disturbance in systems with moving parts, can be a valid energy source.

[0005] The main needs that are felt in the field of systems for harvesting energy from environmental sources include minimum consumption of energy of the components of the systems themselves, maximum efficiency for harvesting, conversion, and storage of energy, and the need to supply the energy stored to a plurality of devices different from one another that use it for their operation.

[0006] FIG. **1** is a schematic illustration, by means of functional blocks, of an energy harvesting system of a known type.

[0007] The energy harvesting system **1** of FIG. **1** comprises: a transducer **2**, for example of an electromagnetic or piezoelectric type, subjected in use to environmental mechanical vibrations and configured for converting mechanical energy into electrical energy; a scavenging interface **4**, for example comprising a rectifier circuit, configured for receiving at input an AC signal generated by the transducer **2** and supplying at output a DC signal for charging a capacitor **5** connected to the output of the scavenging interface **4**; and a DC-DC converter **6**, connected to the capacitor **5** for receiving at input the electrical energy stored by the capacitor **5** and supplying it to an electrical load **8**.

[0008] The global efficiency η_{TOT} of the energy harvesting system **1** is given by Eq. (1) below:

$$\eta_{TOT}=\eta_{TRANSD}\cdot\eta_{SCAV}\cdot\eta_{DCDC} \tag{1}$$

[0009] where: η_{TRANSD} is the efficiency of the transducer **2**, indicating the amount of energy available in the environment that has been effectively converted, by the transducer **2**, into electrical energy; η_{SCAV} is the efficiency of the scavenging interface **4**, indicating the energy consumed by the scavenging interface **4** and the factor of impedance decoupling between the transducer and the interface; and η_{DCDC} is the efficiency of the DC-DC converter **6**.

[0010] As is known, in order to supply to the load the maximum power available, the impedance of the load should be equal to that of the source. As illustrated in FIG. **2**, the transducer **2** can be represented schematically, in this context, as a voltage generator **3** provided with an internal resistance R_S of its own. The maximum power P_{TRANSD}^{MAX} that the transducer **2** can supply at output may be defined as:

$$P_{TRANSD}^{MAX}=V_{TRANSD\_EQ}^{2}/4R_S;\ \text{if } R_{LOAD}=R_S \tag{2}$$

[0011] Where: V_{TRANSD_EQ} is the voltage produced by the equivalent voltage generator; and R_{LOAD} is the equivalent electrical resistance on the output of the transducer **2** (or, likewise, seen at input to the scavenging interface **4**), which takes into due consideration the equivalent resistance of the scavenging interface **4**, of the DC-DC converter **6**, and of the load **8**.

[0012] On account of the impedance decoupling ($R_{LOAD}\neq R_S$), the power at input to the scavenging interface **4** is lower than the maximum power available P_{TRANSD}^{MAX}.

[0013] The power P_{SCAV} stored by the capacitor **5** is a fraction of the power recovered by the interface, and is given by Eq. (3):

$$P_{SCAV}=\eta_{TRANSD}\cdot\eta\text{SCAV}\cdot P_{TRANSD}^{MAX} \tag{3}$$

[0014] whilst the power P_{EL_LOAD} supplied at output by the DC-DC converter to the electrical load **8** is given by the following Eq. (4):

$$P_{EL\_LOAD}=P_{DCDC}\cdot\eta_{DCDC} \tag{4}$$

[0015] where P_{DCDC} is the power received at input by the DC-DC converter **8**, in this case coinciding with P_{SCAV}.

[0016] The main disadvantage of the configuration according to FIG. **1** regards the fact that the maximum voltage supplied at output by the scavenging interface **4** is limited by the input dynamics of the DC-DC converter **8**.

[0017] The voltage V_{OUT} across the capacitor **5** (supplied at output by the scavenging interface **4** and at input to the DC-DC converter **8**) is in fact determined on the basis of the power balancing according to the following Eq. (5):

$$P_{STORE}=P_{SCAV}-P_{DCDC} \tag{5}$$

[0018] where P_{STORE} is the excess power with respect to the power required by the load, recovered by the interface and stored in the capacitor.

[0019] In applications where the transducer **2** converts mechanical energy into electrical energy in a discontinuous way (i.e., the power P_{TRANSD}^{MAX} varies significantly in time) and/or the power P_{EL_LOAD} required by the electrical load **8** varies significantly in time, also the voltage V_{OUT} consequently presents a plot that is variable in time.

[0020] This causes, for example, a variation of the efficiency factor η_{DCDC}, which assumes low values at high values of V_{OUT}. The maximum value of V_{OUT} is moreover limited by the range of input voltages allowed by the DC-DC converter. Maximization of the window of values allowed at input by the DC-DC converter **6** requires a specific design of the DC-DC converter; however, also in the latter case, an upper limit of the range of allowable values for V_{OUT} is imposed.

[0021] There is a need in the art to provide system and a method for efficiently harvesting environmental energy that will enable the aforesaid problems and disadvantages to be overcome.

SUMMARY

[0022] In accordance with an embodiment, a system and method enable maximization of the storage of electrical charge without requiring constraints of design of other components of the system itself, maximizing the global efficiency.

[0023] According to the present invention a system and a method for efficiently harvesting environmental energy are provided as defined in the annexed claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0024] For a better understanding of the present invention, preferred embodiments thereof are now described, purely by way of non-limiting example and with reference to the attached plates of drawings, wherein:

[0025] FIG. **1** shows an energy harvesting system according to a known embodiment;

[0026] FIG. **2** shows an equivalent circuit representation of the system of FIG. **1**;

[0027] FIG. **3** shows an energy harvesting system according to one embodiment of the present invention;

[0028] FIG. **4** shows at a greater circuit detail the system of FIG. **3**;

[0029] FIG. **5** shows the system of FIG. **3** during a first operating step;

[0030] FIG. **6** shows the system of FIG. **3** during a second operating step;

[0031] FIG. **7** is a schematic illustration of control logic for the system of FIG. **3**;

[0032] FIG. **8** shows a hysteresis curve of a hysteretic comparator of the control logic of FIG. **7**;

[0033] FIGS. **9** and **10** show the time plots of electrical signals internal to the system of FIG. **3**; and

[0034] FIG. **11** shows a vehicle comprising the system of FIG. **3**.

DETAILED DESCRIPTION OF THE DRAWINGS

[0035] FIG. **3** shows an energy harvesting system **10** according to one embodiment.

[0036] In a way similar to what is illustrated in FIG. **1** and described with reference to said figure, the energy harvesting system **10** comprises the transducer **2** and the scavenging interface **4**, electrically coupled to one another in a way in itself known.

[0037] The energy harvesting system **10** further comprises: a first storage element **12**, for example one or more capacitors; a second storage element **16**, for example one or more capacitors; a switch **14**, connected between the first storage element **12** and the second storage element **16**, which can be operated for connecting the first and second storage elements **12**, **16** to one another; and the DC-DC converter **6**, electrically coupled to the second storage element **16** and configured for supplying one or more loads **18***a* . . . **18***n* connected to respective outputs **6***a* . . . **6***n* of the DC-DC converter **6**.

[0038] In greater detail, as illustrated in FIG. **4**, the scavenging interface **4** comprises, according to one embodiment, a rectifier **20**, for example comprising diodes **21** connected to one another to form a Graetz-bridge structure **22**. The rectifier **20** has the function of receiving at input an AC signal (for example, a voltage signal) generated by the transducer **2** and supplying at output a corresponding DC signal (once again, a voltage signal). It is evident that the rectifier **20** is not necessary in the case where the transducer **2** is configured for generating at output a DC signal (in particular, a voltage signal) V_{TRANSD}.

[0039] The input terminals of the bridge structure **22** are connected to respective output terminals of the transducer **2** so as to be biased at the input voltage V_{TRANSD} generated at output by the transducer **2**. The output terminals of the bridge structure **22** are, instead, connected between a ground reference terminal GND, at reference voltage V_{REF}, and a biasing terminal **24**, at voltage V_{OUT_INT}. The first storage element **12** is connected between the biasing terminal **24** and the ground reference terminal GND, and, in use, is charged to a voltage $V_{OUT\_NT}-V_{REF}$. For example, the voltage V_{REF} is 0 V. The voltage V_{REF} can, however, assume values other than 0 V, for example be in a neighborhood of 0 V, or assume other values still, higher or lower than of 0 V, indifferently.

[0040] The switch **14** is connected between the biasing terminal **24** and an intermediate terminal **26**. The second storage element **16** is connected between the ground reference terminal GND and the intermediate terminal **26**. In this way, in use, the switch **14** can be operated for coupling the second storage element **16** with the biasing terminal **24**, providing ideally a connection in parallel between the first and second storage elements **12**, **16** and, alternately, uncoupling the second storage element **16** from the biasing terminal **24** insulating electrically the first storage element **12** from the second storage element **16**. The switch **14** is controlled in opening and closing by an appropriate control logic **28**, which will be described more fully in what follows.

[0041] In use, the voltage V_{OUT_INT} generated at output by the scavenging interface **4** is stored in the first storage element **12**. In the case where the switch **14** is open, there is no transfer of charge from the first storage element **12** to the second storage element **16** and the DC-DC converter **6**. The switch **14** can be driven in closing for the time necessary to charge the second storage element **16**, by transfer of charge from the first storage element **12**. Once a desired state of charge of the second storage element **16** has been reached, the switch **14** is opened, insulating the first storage element **12** from the second storage element **16**.

[0042] The first storage element **12** is configured for storing a high electrical charge. In particular, the storage element **12** is an element of a capacitive type having a capacitance C_1 of between 10 μF and 100 μF, for example equal to 50 μF. The second storage element **16** is also of a capacitive type, having a capacitance C_2 of between 1 μF and 20 μF, for example equal to 10 μF. The second storage element **16** is moreover configured in such a way that the voltage that is set up between its conduction terminals does not exceed the range of voltages allowed at input by the DC-DC converter **6** used. In this way, it is possible to use DC-DC converters **6** of a known type, designed without particular constraints of input dynamics deriving from the specific technical application.

[0043] If V_L is the lower limit of the range of voltages allowed at input by the DC-DC converter, and V_H is the upper limit of the range of voltages allowed at input by the DC-DC converter, the condition that brings about opening of the switch **14** is given by $V_{IN\_CONV}>V_H$, whereas the condition that brings about closing of the switch **14** is given by $V_{IN\_CONV}<V_L$. Hence, in use, we find that $V_L<V_{IN\_CONV}<V_H$. Said condition is ensured, in use, by the logic **28**, which implements, for example, a hysteretic algorithm such as to satisfy the aforesaid condition for the voltage V_{IN_CONV}.

[0044] FIG. **5** shows a portion of the energy harvesting system **10** during an operating step in which the switch **14** is open, in particular during a step of charging of the first storage element **12** via the energy supplied by the transducer **2** and of simultaneous supply of the DC-DC converter **6** by means of the second storage element **16**. The DC-DC converter **6** is supplied at input by the charge stored in the second storage element **16**, which consequently, during the step according to FIG. **5**, decreases. The first storage element **12** is electrically uncoupled from the load **18**a . . . **18**n and receives at input the voltage V_{TRANSD} appropriately rectified by the scavenging interface **4** (and reduced by a factor depending upon the efficiency η_{TRANSD} of the scavenging interface **4**). The first storage element **12** is hence charged.

[0045] With reference to what has been described in regard to FIG. **5**, it is evident that the supply of the DC-DC converter **6** is possible only if the second storage element **16** has been previously pre-charged. In an initial step of start-up of the energy harvesting system **10**, the operating step of FIG. **5** comprises the step of charging both the first and the second storage elements **12**, **16**, in a way similar to what is described in what follows with reference to FIG. **6**.

[0046] FIG. **6** shows a portion of the energy harvesting system **10** during an operating step in which the switch **14** is closed. Said operating condition is achieved when the voltage V_{IN_CONV} across the second storage element **16** drops below the limit value V_L and in the start-up step when both the first and the second storage elements **12**, **16** are discharged. In this case, the logic **28** controls the switch **14** in closing. The first and second storage elements **12**, **16** are hence electrically coupled to one another via the connection provided by the switch **14** closed (ideally, considering a switch **14** with zero internal resistance, they are connected in parallel to one another), and there is a transfer of charge between the first and second storage elements **12**, **16**. In particular, the second storage element is charged by means of the charge stored in the first storage element **12**. Consequently, in the absence of supply by the transducer **2** (via the scavenging interface **4**), the voltage V_{OUT_INT} drops and the voltage V_{IN_CONV} increases up to the value V_H (provided that, of course, the voltage V_{OUT_INT} is sufficiently high as to enable the voltage V_{IN_CONV} to reach the value V_H). When the value $V_{IN\_CONV}=V_H$ is reached, the logic **28** controls the switch **14** in opening, and flow returns to the condition of FIG. **5**.

[0047] FIG. **7** is a schematic illustration of the control logic **28**, configured for controlling the switch **14** in opening and closing, according to one embodiment of the present invention.

[0048] The control logic **28** comprises: a first resistor **32** and a second resistor **34**, connected between the intermediate terminal **26** and the ground reference terminal GND; a comparator **36**, including a first input terminal configured for receiving a reference signal V_R at input, a second input terminal connected between the first and second resistors **32**, **34** for receiving a partition signal V_p proportional to the signal V_{IN_CONV}, and an output terminal for supplying at output a comparison signal V_{COMP} indicating a result of the comparison between the reference signal V_R and the partition signal V_P; a control circuit **38**; and a driving circuit **40**, connected to the control circuit **38**.

[0049] The comparator **36** is a hysteretic comparator, of a known type. The comparator hence receives at input the signal to be monitored (partition signal V_P) and the reference signal V_R, around which it generates, in a known way, the hysteresis. The triggering thresholds are hence $V_H'=V_R+V_{HYST}/2$ and $V_L'=V_R-V_{HYST}/2$ (see also FIG. **8**). Alternatively, the comparator **36** can be without hysteresis. In this case, the comparison signal V_{COMP} varies when the partition signal V_P rises/drops with respect to the threshold value given by the reference signal V_R. A hysteretic comparator is advantageous as compared to a non-hysteretic comparator in so far as it is less subject to undesirable variations of the output signal (comparison signal V_{COMP}) due to electrical noise.

[0050] The control circuit **38** is configured for receiving at input the comparison signal V_{COMP} and, on the basis of the value assumed by the comparison signal V_{COMP}, controlling, via the driving circuit **40**, the switch **14** in opening and closing. The control circuit **38** is, for example, a microprocessor circuit configured for carrying out the aforementioned step of checking on the comparison signal V_{COMP}. Furthermore, the control circuit **38** and the driving circuit **40** can be built in integrated form as a single control and driving circuit.

[0051] The switch **14** is, for example, a MOSFET of a P type, having a first conduction terminal (source terminal), connected to the biasing terminal **24**, a second conduction terminal (drain terminal), connected to the intermediate terminal **26**, and a control terminal (gate terminal). In this case, the switch **14** is of a type designed to sustain high voltages between its source and drain terminals (e.g., drift MOS, DMOS, etc.). The diode **41** must be connected as illustrated in FIG. **7** in order to prevent conduction when the switch **14** is open.

[0052] In detail, the diode **41** is connected between the source terminal S and the drain terminal D of the switch **14**, in antiparallel configuration (with respect to the normal direction of flow of the current through the switch **14**). As is known, a characteristic of a MOSFET is that of displaying, under certain operating conditions, the electrical properties of a diode (parasitic diode). Said diode is electrically set (integrated) between the source and drain terminals of the MOSFET. In other words, the switch **14** can present the electrical behavior of a diode, in which the cathode of the diode corresponds to the source terminal and the anode to the drain terminal. The diode **41** is hence the diode integrated in the MOSFET that forms the switch **14**.

[0053] If technologies different from MOSFET technology are used for the switch **14**, the diode **41** may not be present.

[0054] The driving circuit **40** is connected to the gate terminal of the switch **14** and is configured for biasing appropriately the gate terminal of the switch **14** in order to drive the transistor in conduction or inhibition. Said circuit is in effect a level shifter capable of converting the signal (typically at low voltage) produced by the control logic **38** into a CMOS signal referenced to the terminal **24** (source of the switch **14**). By so doing it is possible to generate a correct driving signal of the switch **14** without jeopardizing operation thereof and without damaging the gate oxide thereof.

[0055] The value of resistance of the resistors **32** and **34** is chosen as high as possible according to the area on silicon available so as to guarantee the lowest current absorption at the node **26**, and so as to maximize the overall efficiency of the system **10**. The ratio between the resistors **32** and **34** is chosen so as to be able to compare the voltage at the node **26** with the low-voltage reference V_R normally generated by a bandgap circuit.

[0056] The comparator **36** is a hysteretic comparator, of a type in itself known. As illustrated schematically in FIG. **8**, the comparator **36** is provided with two different triggering thresholds: a lower threshold (positioned at a value V_L' proportional to V_L) for falling-edge values of the signal V_P applied at input to the comparator **36**, and an upper threshold (positioned at a value V_H' proportional to V_H) for rising-edge values of the signal V_P applied at input to the comparator **36**. For example, $V_L'=3$ V and $V_H'=20$ V.

[0057] The output V_{COMP} of the comparator **36** assumes two values, indicated in FIG. **8** as V_{COMP}^{+} and V_{COMP}^{-}. FIG. **8** exemplifies a comparator **36** with hysteresis around the value of the reference V_R.

[0058] In use, during charging of the second storage element **16**, the output of the comparator **36** is at the value V_{COMP}^{-}; the switch **14** is driven into a closed state by the control circuit **38** and by the driving circuit **40**; and the voltage V_{IN_CONV} across the second storage element **16** increases until it reaches the value V_H. When the voltage V_{IN_CONV} reaches a value equal to V_H (i.e., the voltage V_P reaches a value equal to V_H'), the output V_{COMP} of the comparator **36** switches from V_{COMP}^{-} to V_{COMP}^{+}. The control logic **38**, via the driving circuit **40**, opens the switch **14**, and the DC-DC converter **6** is supplied at input exclusively by the second storage element **16**. Then, the voltage V_{IN_CONV} (i.e., the signal V_P) decreases until it reaches the lower limit value V_L (i.e., V_L'); at this point, the output V_{COMP} of the comparator **36** switches to the value V_{COMP}^{-} and the control logic **38**, via the driving circuit **40**, closes the switch **14**, and the second storage element **16** is again charged by means of the charge stored in the first storage element **12**.

[0059] What has been described above is also illustrated in FIGS. **9** and **10**, which show the time plots of the signals V_{TRANSD} (FIG. **9**), and V_{OUT_INT} and V_{IN_CONV} (FIG. **10**). It should here be noted that the signal V_{TRANSD}, supplied at output by the transducer **2**, has an ideal time plot of an impulsive type, with pulses having all the same amplitude and the same frequency (they are uniform in time with respect to one another). The signal V_{OUT_INT} is defined on the basis of the ideal signal V_{TRANSD}. Each pulse of the signal V_{TRANSD} of the transducer **2** generates an increase in the signal V_{OUT_INT}, which assumes a steplike local profile. A real signal source V_{TRANSD} is typically of a discontinuous type, with pulses having amplitudes different from one another and random onset frequency. A source of this type will cause a corresponding variation of the profile of increase of the signal V_{OUT_INT}.

[0060] In an initial step of start-up of the energy harvesting system **10** (not illustrated in FIG. **10**), the voltage present across the first storage element **12** is lower than the value V_L. The switch **14** is closed and the transducer **2** supplies energy to the first and second storage elements **12**, **16**, charging them (time interval preceding time T_1). Then, when the voltage across the first and second storage elements **12**, **16** reaches the limit value of V_H (time t_1), the switch **14** is opened. The voltage V_{IN_CONV} across the second storage element **16** starts to decrease, whilst the voltage V_{OUT_INT} across the first storage element **12** continues to rise (i.e., the process for charging the first storage element **12** continues).

[0061] Of course, what has been illustrated in FIGS. **9** and **10** indicates an optimal operating condition, in which the environmental energy converted by the transducer **2** is sufficiently high and such as to be higher than the energy used for charging the second storage element **16** and used by the electrical load **18***a*, . . . , **18***n*.

[0062] When the voltage V_{IN_CONV} reaches the lower-limit value $V_{IN\_CONV}=V_L$ (time t_2), the switch **14** is closed and there is a transfer of charge from the first storage element **12** to the second storage element **16**. The voltage V_{IN_CONV} increases until the value $V_{IN\_CONV}=V_H$ is reached (time t_3).

[0063] The switch **14** is then opened again, and the step of discharge of the second storage element **16** is resumed.

[0064] As is known, the operation of charge sharing between the first storage element **12** and the second storage element **16** following upon closing of the switch **14** is the cause of a power loss due to the presence of the switch **14** itself. This causes a consequent reduction in the global efficiency of the energy harvesting system **10**. The power P_{CHARGE} useful for charging the second storage element **16** is given by the following Eq. (6):

$$P_{CHARGE}=P_{SCAV}-P_{CONV}-P_{SH} \tag{6}$$

[0065] where P_{SH} is the mean power lost during the operation of charge sharing.

[0066] The mean power P_{SH} is defined as the ratio between the energy lost ΔE and the time interval T_{SH} elapsing between a given charge-sharing event and a subsequent charge-sharing event (for example, with reference to FIG. **10**, the interval t_2-t_4).

[0067] The energy ΔE and the interval T_{SH} are defined by Eqs. (7) and (8):

$$T_{SH}=\frac{0.5\cdot C_2\cdot(V_H^2-V_L^2)}{\eta_{DCDC}\cdot P_{LOAD}} \tag{7}$$

$$\Delta E=0.5\cdot C_2\cdot(V_H-V_L)\cdot\left[2\cdot V_{OUT}+(V_H-V_L)\cdot\left(\frac{C_1-C_2}{C_1}\right)\right] \tag{8}$$

[0068] Consequently, P_{SH} is given by Eq. (9):

$$P_{SH}=\frac{\Delta E}{T_{SH}}=\left[\frac{2\cdot V_{OUT}-\frac{C_2}{C_1}\cdot(V_H-V_L)}{(V_H-V_L)}-1\right]\cdot\eta_{DCDC}\cdot P_{LOAD} \tag{9}$$

[0069] If the charge balancing is positive, the voltage V_{OUT_INT} across the first storage element **12** increases during the cycles T_{SH}; otherwise, it decreases. In order to maximize the value of energy stored in the first storage element **12** (and hence maximize the interval T_{SH}), it is advisable to maximize the threshold value V_H, which in any case must be kept within the input dynamics of the DC-DC converter **6**. It is hence advisable to use DC-DC converters **6** with high input dynamics (in particular, with an upper limit of input dynamics of a value that is as high as possible) so as to enable high threshold values V_H.

[0070] When the interval T_{SH} is maximized, the power dissipated on account of operations of charge sharing is reduced in so far as also the frequency of occurrence of the latter is reduced.

[0071] FIG. **11** shows a vehicle **100** comprising the energy harvesting system **10**, according to one embodiment of the present invention. The vehicle **100** is, in particular, a motor vehicle. It is evident, however, that the energy harvesting system **10** can be used in any vehicle **100** or in systems or apparatuses other than a vehicle. In particular, the energy harvesting system **10** can find application in generic systems in which it is desirable to harvest, store, and use environmental energy, in particular by means of conversion of mechanical energy into electrical energy.

[0072] With reference to FIG. **11**, the vehicle **100** comprises one or more transducers **2** coupled in a known way to a portion of the vehicle **100** that is subject to mechanical stresses and/or vibrations, for converting said mechanical stresses and/or vibrations into electric current.

[0073] The energy harvesting system **10** is connected to one or more electrical loads **18***a* . . . **18***n*. In particular, according to one application of the present invention, the electrical loads **18***a* . . . **18***n* comprise TPM (tire-parameter monitoring) sensors **50** for monitoring parameters of tires **102**. In this case, the TPM sensors **50** are coupled to an internal portion of the tires **102** of the vehicle **100**. Likewise, also the transducers **2** (for example, of an electromagnetic or piezoelectric type) are coupled to an internal portion of the tire **102**. The stress on of the transducers **2** when the vehicle **100** is travelling causes the production of a current/voltage electrical signal at output from the transducer **2** by means of conversion of the mechanical energy into electrical energy. The electrical energy thus produced is stored, as described previously, in the first storage element **12**, and supplied, when necessary, to the second storage element **16**, which in turn makes it available for the DC-DC converter **6** to which two or more TPM sensors **50** are connected. Thanks to the fact that the first storage element **12** has a capacitance greater than that of the second storage element **16**, which is not constrained by parameters of design of the DC-DC converter **6**, when the vehicle **100** stops it is in any case possible to supply the TPM sensors **50** using the electrical energy stored in the first storage element **12**. By appropriately sizing the first storage element **12** it is possible to increase or reduce as desired the range of autonomy of supply of the TPM sensors **50** when the vehicle is stationary.

[0074] According to one embodiment of the present invention, the energy harvesting system **10**, comprising one or more transducers, and the TPM sensors, are glued inside one or more tires **102**.

[0075] The impact of the tire **102** on the ground during motion of the vehicle **100** enables production of electrical energy.

[0076] As an alternative to what is illustrated in FIG. **11**, the energy harvesting system **10** can be set in any other portion of the vehicle **100**, and/or used for supplying an electrical load other than or additional to the TPM sensors **50**.

[0077] Another possible application of the energy harvesting system **10** is the generation of electrical energy by exploiting the mechanical energy produced by an individual when he is walking or running. In this case, the energy harvesting system **10** is located inside the shoes of said individual (for example, inside the sole). In systems aimed at fitness, where it is particularly interesting to count the steps, it is useful to recover energy from the vibrations induced by walking/running to be able to supply without the use of a battery acceleration sensors and/or RFID transmitters capable of communicating with cellphones, devices for playing music, or with any other apparatus involved in information on the steps performed.

[0078] From an examination of the characteristics of the invention obtained according to the present disclosure the advantages that it affords are evident.

[0079] In particular, the system according to the present invention has a high efficiency and autonomy irrespective of external conditions, such as possible energy peaks acquired by the transducer or a temporary absence of energy. In fact, the first storage element **12**, which has a high capacity for storing energy, has the function of reserving energy in situations of temporary absence of energy; the switch **14** is configured for uncoupling, when necessary, the first storage element **12** from the DC-DC converter **6** and from the load of the latter, rendering operativeness of the energy harvesting system **10** independent of any particular temporary conditions external to the system itself.

[0080] Furthermore, the architecture proposed for the energy harvesting system **10** enables use of standard electronic components, i.e., ones not developed purposely for this application (for example, the DC-DC converter **6** does not need to be designed to satisfy particular conditions of input dynamics), which means a considerable economic saving and saving in terms of overall efficiency.

[0081] Finally, the hysteretic control of the switch **14** enables storage of a high electrical charge in the capacitor **16** without jeopardizing the functionality of the DC-DC converter **6** and without requiring any modification thereof.

[0082] Finally, it is clear that modifications and variations may be made to what has been described and illustrated herein, without thereby departing from the sphere of protection of the present invention, as defined in the annexed claims.

[0083] For example, there may be present a plurality of transducers **2**, all of the same type or of a type different from one another, indifferently. For example, the transducer/transducers can be chosen in the group comprising: electrochemical transducers (designed to convert chemical energy into an electrical signal), electromechanical transducers (designed to convert mechanical energy into an electrical signal), electroacoustic transducers (designed to convert variations of pressure into an electrical signal), electromagnetic transducers (designed to convert a magnetic field into an electrical signal), photoelectric transducers (designed to convert light energy into an electrical signal), electrostatic transducers, or thermoelectrical transducers.

What is claimed is:

1. A system, comprising:

a transducer configured to convert energy coming from an external energy source into an electrical signal;

a first storage element coupled to an output of the transducer and configured to receive said electrical signal and store electrical energy,

a second storage element configured to store electrical energy; and

a switch coupled between the first and the second electrical-energy storage elements and operable to electrically couple the first and second storage elements to one another and, alternatively, uncouple the first and second storage elements from one another.

2. The system according to claim **1**, wherein the first storage element comprises a first conduction terminal and a second conduction terminal, wherein the second storage element comprises a first conduction terminal and a second conduction terminal, wherein the second conduction terminals of the first and second storage elements are connected to a common reference terminal, wherein the first conduction terminals of the first and second storage elements are connected to respective terminals of the switch in such a way that, when the switch is operated to electrically couple the first and second storage elements, the respective first conduction terminals of the first and second storage elements are coupled to one another.

3. The system according to claim **1**, wherein said first storage element has an electrical energy storage capacity greater than that of said second storage element.

4. The system according to claim **1**, further comprising control logic having an output coupled to control said switch, said control logic configured to close the switch when the electrical energy stored in the second storage element is lower than a first threshold value, and further configured to open the switch when the electrical energy stored in the second storage element is higher than a second threshold value.

5. The system according to claim **4**, wherein the control logic comprises:

a comparator with hysteresis configured to receive on a first input a first comparison signal indicative of electrical energy stored in the second storage element, and receive on a second input a second predefined comparison signal, and supply at the output a third comparison signal indicative of a result of a comparison between the first and second comparison signals;

a control and driving circuit configured to receive the third comparison signal and, on the basis of the third comparison signal, control opening or closing of the switch.

6. The system according to claim **1**, wherein the first storage element includes a capacitor and wherein the electrical signal generated by the transducer is an AC voltage signal, the system further comprising a scavenging interface having an input connected to the transducer and an output connected to the first storage element, the scavenging interface configured to receive at an input the electrical signal and generate at an output a first intermediate DC signal to charge the first storage element.

7. The system according to claim **1**, further comprising a DC-DC converter coupled between the second storage element and an electrical load, said DC-DC converter configured to receive a second intermediate signal depending upon the electrical energy stored in the second storage element and supply said electrical load via said second intermediate signal.

8. The system according to claim **7**, wherein the second storage element includes a capacitor having biasing terminals, the DC-DC converter further configured to accept a voltage signal having a value lower than a maximum value, and the second storage element being configured in such a way that the difference of potential that, in use, is set up across its terminals has a value lower than said maximum value.

9. The system according to claim **1**, comprising an energy-harvesting system for use in harvesting energy from movement of a support.

10. The system according to claim **9**, wherein said support is a means of transport.

11. The system according to claim **9**, wherein said transducer is chosen in the group comprising: electrochemical transducer, electromechanical transducer, electroacoustic transducer, electromagnetic transducer, photoelectric transducer, electrostatic transducer, thermoelectrical transducer.

12. An energy-harvesting method, comprising:

converting, by a transducer, energy from an external energy source into electrical energy to generate an electrical signal;

storing said electrical energy in a first storage element;

coupling the first storage element to a second storage element so as to store, in the second storage element, at least a portion of the electrical energy stored in the first storage element;

alternatively, uncoupling the first storage element from the second storage element so as to insulate the first storage element from the second storage element; and

during uncoupling, supplying an electrical load with electrical energy stored in the second storage element.

13. The method according to claim **12**, further comprising monitoring the electrical energy stored in the second storage element, wherein a coupling of the first storage element to the second storage element is carried out when the electrical energy stored in the second storage element falls lower than a first threshold value, and wherein uncoupling of the first storage element from the second storage element is carried out when the electrical energy stored in the second storage element rises higher than a second threshold value.

14. The method according to claim **12**, wherein monitoring:

supplying, on a first input of a comparator with hysteresis, a first comparison signal indicative of the electrical energy stored in the second storage element;

supplying, on a second input of the comparator with hysteresis, a second predefined comparison signal; and

generating, at an output of the comparator with hysteresis, a third comparison signal indicative of a result of a comparison between the first and second comparison signals,

wherein said coupling and uncoupling actions are performed on the basis of a value assumed by the third comparison signal.

15. The method according to claim **12**, wherein the first storage element includes a capacitor and wherein the electrical signal generated by the transducer is an AC voltage signal, the method further comprising:

rectifying the electrical signal generated by the transducer to generate a first intermediate DC signal; and

charging the first storage element with the first intermediate signal.

16. A circuit, comprising:

a first capacitor having a first terminal coupled to a reference voltage node and a second terminal coupled to an input node and configured to store first electrical energy;

a second capacitor having a third terminal coupled to said reference voltage node and a fourth terminal and configured to store second electrical energy;

a switching circuit having an input terminal coupled to the first terminal and an output terminal coupled to the fourth terminal;

a hysteresis comparator coupled to sense the second electrical energy at the fourth terminal and configured to close the switching circuit in response to sensed second electrical energy falling below a first threshold and open the switching circuit in response to sensed electrical energy rising above a second threshold.

17. The circuit of claim **16**, further comprising a rectifying circuit configured to rectify an AC signal to generate an DC signal at said input node.

18. The circuit of claim **17**, further comprising a transducer circuit configured to convert non-electrical energy into said AC signal.

19. The circuit of claim **18**, further comprising a DC-DC converter circuit having an input coupled to said fourth terminal and configured to supply power to a load from the second electrical energy.

20. The circuit of claim **16**, wherein said first capacitor has an electrical energy storage capacity greater than that of said second capacitor.

(57) **ABSTRACT**

The subject matter described herein is an atmospheric energy collector. The atmospheric energy collector includes of a windsock arrangement that has a large up-wind opening on one side and that tapers from the larger up-wind opening on the one side to a small down-wind opening on the other side. The up-wind side is secured to a tether such that an electrically conducting material (e.g. metal) included in construction of the atmospheric energy collector is connected to the tether. The windsock arrangement is extended outwards by wind and the like atmospheric conditions such that the electrically conducting material collects the atmospheric energy and transfers the collected energy to the tether.

FIG. 6

ATMOSPHERIC ENERGY COLLECTION

TECHNICAL FIELD

[0001] The subject matter described herein relates to a light-weight, extendible electricity collecting windsock arrangement comprising an enhanced collection surface for atmospheric electrical energy collection.

BACKGROUND

[0002] The atmosphere above the earth is known to include electrical charge. The earth's surface is negatively charged, while the air above it is positively charged. All atmospheric effects are a result of an interplay between these two huge areas of opposite electrical energy. The potential difference between the positively charged atmosphere and the negatively charged earth surface causes atmospheric electrical energy to be developed. Some of this atmospheric electrical energy may be experienced through thunderstorms.

[0003] Even though there is a huge amount of atmospheric electrical energy in the atmosphere, collection of the atmospheric electrical energy still remains a problem. Due to high voltage and low current conditions, there is a need for large collection surfaces for maximizing the collection of atmospheric electrical energy. Note that the terms atmospheric electricity, atmospheric energy, and atmospheric electrical energy have been used interchangeably in this specification.

[0004] The problem of low current is compounded by a heavy weight of the collectors of atmospheric electrical energy. The heavy weight of the collectors increases payload requirements of a lift mechanism, which may be used to lift the collectors to an appropriate height or altitude so that the collection of atmospheric electrical energy is maximized. Thus, a need exists for large yet light-weight collectors such that payload requirements for the lift mechanism remain reasonable.

SUMMARY

[0005] The subject matter described herein relates to an atmospheric energy collector. The atmospheric energy collector includes an electricity collecting windsock arrangement that has a large up-wind opening on one side and that tapers from the larger up-wind opening on the one side to a small down-wind opening on the other side. The up-wind side is secured to a tether such that an electrically conducting material (e.g. metal) included in construction of the atmospheric energy collector is connected to the tether. The electricity collecting windsock arrangement is extended outwards by wind and the like atmospheric conditions such that the electrically conducting material collects the atmospheric energy and transfers the collected energy to the tether. Further, the electricity collecting windsock includes light-weight collectors such that payload requirements for the lift mechanism remain reasonable (i.e. remain within a predetermined value).

[0006] In one aspect, an electricity collection apparatus includes a tether and a windsock. The windsock is formed of an insulation material with a metal deposited on at least a portion of the insulation material. The metal of the windsock is electrically connected to the tether. The windsock extends in a direction of ambient wind to provide a surface area based on the ambient wind, and the surface area provides the metal to collect electrical energy from the ambient wind, the collected electrical energy being transferred to the tether.

[0007] In another aspect, an electricity collection apparatus includes a windsock formed of an insulation material the windsock to extend in a direction of ambient wind to provide a surface area based on the ambient wind. The apparatus further includes one or more electrical conductors provided on at least a portion of the insulation material to collect electrical energy from the ambient wind. The apparatus further includes an electrically conductive tether connected with windsock to anchor the windsock in the direction of the ambient wind, the electrically conductive tether being electrically connected to the one or more electrical conductors provided on at least a portion of the insulation material to transfer the collected electrical energy from the one or more electrical conductors to an electrical storage.

[0008] The subject matter described herein provides many advantages. For example, large collection surfaces allow a maximized collection of atmospheric energy. Moreover, the light-weight collectors allow payload requirements for the lift mechanism to remain reasonable (i.e. remain within a predetermined value).

[0009] The details of one or more variations of the subject matter described herein are set forth in the accompanying drawings and the description below. Other features and advantages of the subject matter described herein will be apparent from the description and drawings, and from the claims.

DESCRIPTION OF DRAWINGS

[0010] The accompanying drawings, which are incorporated in and constitute a part of this specification, show certain aspects of the subject matter disclosed herein and, together with the description, help explain some of the principles associated with the disclosed implementations. In the drawings,

[0011] FIG. **1**A illustrates extendible electricity collecting windsock arrangement that is used for collection of atmospheric electrical energy in accordance with implementations of the current subject matter;

[0012] FIG. **1**B illustrates a cross-section of one implementation of the electrically conducting windsock in accordance with implementations of the current subject matter;

[0013] FIG. **1**C illustrates a cross-section of another implementation of the electricity collecting windsock in accordance with implementations of the current subject matter;

[0014] FIG. **2** illustrates an exemplary conductive line in accordance with implementations of the current subject matter;

[0015] FIG. **3**A illustrates a front view of a conductive line in accordance with implementations of the current subject matter;

[0016] FIG. **3**B illustrates a top view of the conductive line shown in FIG. **3** in accordance with implementations of the current subject matter;

[0017] FIGS. **4**A, **4**B, and **4**C illustrate electrical schematics for handling the static charge from the atmosphere in accordance with implementations of the current subject matter;

[0018] FIG. **5** illustrates an adjusting apparatus (winch motor and spool) that enables adjustment of location/height of the electricity collecting windsock arrangement in accordance with implementations of the current subject matter; and

[0019] FIG. **6** is a process flow diagram illustrating aspects of a method in accordance with implementations of the current subject matter.

[0020] When practical, similar reference numbers denote similar structures, features, or elements.

DETAILED DESCRIPTION

[0021] To address these and potentially other issues with currently available solutions, one or more implementations of the current subject matter provide methods, systems, articles or manufacture, and the like that can, among other possible advantages, provide an energy collector formed as a windsock and having an enhanced collection surface for atmospheric electrical energy collection. In preferred implementations, an electricity collecting windsock is formed as a flexible cylinder, a truncated cone, or a cone with a metal surface, and is mounted to a mast or other tether so as to capture ambient wind which extends the windsock outward from the mast, in turn forming the largest possible surface area for the wind conditions to enable the metal surface to collect atmospheric amperage. The collected amperage is transferred from the metal surface of the electricity collecting windsock to the mast or tether, and eventually to an electricity storage device. Although implementations in which windsock arrangements having one windsock each are discussed below, those or ordinary skill in the art understand that a windsock arrangement may include two or more windsocks for enhanced atmospheric electricity collection.

[0022] FIG. **1**A illustrates an implementation of electricity collecting windsock arrangement **100** that is used to collect atmospheric electrical energy. The electricity collecting windsock arrangement **100** includes an extendible electricity collecting windsock **102**. The extendible electricity collecting windsock **102** is made of a material that has a high tensile strength and provides electrical insulation. This electrically insulating material **134** (discussed below with respect to FIG. **1**B) may be a plastic or a flexible glass, such as polyester like polyethylene terephthalate (PET) or biaxially-oriented polyethylene terephthalate (BoPET). BoPET is known in the industry by different trade names, some of which are Mylar, Melinex and Hostaphan.

[0023] As is described later with respect to FIGS. **1**B and **1**C, which illustrate cross-sections of implementations of electricity collecting windsock **102**, a thin coat of an electrically conducting material **132**, **162** is deposited on the electrically insulating material **134**. The deposited electrically conducting material **132**, **162** is a good conductor of electricity, and helps electricity collecting windsock **102** to tap atmospheric electrical energy. The electrically conducting material may be any one of a metal or a suitable alloy, such as one of or a combination of one or more of gold, silver, copper, aluminum, and the like.

[0024] The electricity collecting windsock **102** has a large up-wind opening up-wind opening **104** on one side. The electricity collecting windsock **102** tapers from the large up-wind opening **104** on the one side to a small down-wind opening **106** on the other side of the electricity collecting windsock **102**. The up-wind opening **104** has a metal loop **110** on the circumference of the up-wind opening **104**. The metal loop **110** is attached to a tether **112** using an attachment mechanism **114**. The attachment mechanism **114** may include a soldering mechanism. In some implementations, other attachment mechanisms **114** are also known to be used, such as nut and bolt mechanism, threading mechanism, gluing mechanism, and the like. The electricity collecting windsock **102** is extended outwards by wind **116** and/or like atmospheric conditions such that the electrically conducting material (e.g. metal) collects the atmospheric electrical energy and transfers the collected energy to the tether **112**.

[0025] The tether **112** includes a conductive line that is isolated from the ground. The conductive line is used to transfer the collected atmospheric electrical energy from the electricity collecting windsock **102** to an electricity storage device (not shown) where the collected atmospheric charge may be gathered for later or simultaneous use.

[0026] When wind **116** strikes against the electricity collecting windsock arrangement **100** in the direction illustrated, the electricity collecting windsock **102** extends outward, thus allowing the electrically conducting material **132** (discussed below with respect to FIG. **1**B) to collect maximum possible atmospheric electricity. In one implementation, the outward extension **118** is fifty feet or more. When there is no wind, the electricity collecting windsock **102** may be in a relatively compressed state such that the length of the electricity collecting windsock **102** is less than the outward extension **118** caused by windy conditions or like atmospheric conditions. The collected atmospheric electrical energy is communicated to the tether **112**.

[0027] FIG. **1**B illustrates a cross-section **130** of one implementation of the electrically conducting windsock **102**. The cross-section **130** illustrates the electrically conducting material **132** deposited on the inner surface of the electrically insulating material **134**. The electricity collecting windsock **102** includes the electrically conducting material **132** and the electrically insulating material **134** such that the electrically conducting material **132** forms the inner surface of the electricity collecting windsock **102**. When the wind **116** strikes the electricity collecting windsock arrangement, the electricity collecting windsock **102** extends outward, thus allowing the electrically conducting material **132** to collect maximum possible atmospheric electricity. The electrically conducting material **132** may include multiple collectors that are spaced apart such that the collection surface is greatly enhanced. The multiple collectors may be spaced apart in patterns, such as spaced apart lines, squares, rectangles, circles, and the like, or any other pattern that may maximize the collection of the atmospheric electrical energy. As noted above, the electrically insulating material **134** may be a plastic or a flexible glass, such as polyester like polyethylene terephthalate (PET) or biaxially-oriented polyethylene terephthalate (BoPET). The electrically conducting material **132** may be a metal or alloy, such as one of or a combination of one or more of gold, silver, copper, aluminum, and the like.

[0028] FIG. **1**C illustrates a cross-section **160** of another implementation of the electricity collecting windsock **102**. The electrically conducting material (e.g. metal deposit) **132**, **162** may be placed on both sides of the electrically insulating material **134** such that the collection ability is increased even further. Multiple collectors are implemented and are spaced apart on electrically conducting material **132**, **162** such that the collection surface is greatly enhanced. The multiple collectors may form one or more patterns, as noted above with respect to FIG. **1**B. Furthermore, the electrically insulating material **134** (e.g. mylar) used in the electricity collecting windsock **102** is light, thereby minimizing the overall weight of the electricity collecting windsock **102** and reducing the weight for payload calculations. The electrically conducting materials **132**, **162** may be an electrically conducting metal or alloy, such as one of or a combination of at least one of gold, copper, aluminum, silver, and the like. The electrically conducting materials **132**, **162** may be made of the same metal/alloy or a different metal/alloy.

[0029] The electrically conducting materials **132**, **162** may be attached to the electrically insulating material **134** by a gluing mechanism. In some implementations, other attachment mechanisms are known to be implemented, such as paint coating mechanism, a threading mechanism, a nut and bolt mechanism, soldering mechanism, and the like. The attachment mechanism between the electrically conducting material **132** and the electrically insulating material **134** may or may not be the same as the attachment mechanism between the electrically conducting material **162** and the electrically insulating material **134**.

[0030] FIG. **2** illustrates an exemplary conductive line in accordance with one implementation. This type of conductive line is commonly referred to as poly-wire. The conductive line consists of multiple interwoven strands of plastic **202** and **204** woven into a cord or rope arrangement having intertwined therein exposed metal wires **206** and **208**. Although FIG. **2** illustrates two plastic strands and two metal wires, any number of possible combinations of plastic strands and metal wires is possible. The exposed metal wires **206** and **208** attract the atmospheric static charge and transmit the charge down to the electricity storage device (not shown).

[0031] FIG. **3**A illustrates a front view of a conductive line **300** in accordance with another implementation. FIG. **3**B illustrates a top view of the conductive line **300** illustrated in FIG. **3**. The conductive line **300** creates an ionized pathway for the flow of the static charges from the atmosphere to the electricity storage device via the electricity collecting windsock arrangement **100**. This conductive line utilizes a tube **302** having an outer layer **304** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film). The tube **302** provides exceptionally high tensile strength and is chemically and dimensionally stable. In one implementation, the tube **302** may have an ideal diameter of between two and three inches. An interior metal coating **306** provides an initial conduit for the flow of static charge. The static charge through the metal may force the tube **302** to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **302** to become ionized to provide an additional pathway for the atmospheric static charges to the electricity storage device (not shown).

[0032] FIGS. **4**A, **4**B, and **4**C illustrate electrical schematics for handling the static charge from the atmosphere. By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations that may serve the same function.

[0033] Referencing FIG. **4**A, Direct Current In (DC IN) **402** is buffered by a gang of capacitors **404** before being communicated to a DC/AC converter **406**. The DC/AC converter converts the direct current into alternating current suitable for placement over an existing electrical grid **408** such as normally found from a power-plant. Those of ordinary skill in the art readily recognize a variety of DC/AC converters that may work in this capacity.

[0034] FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **402** is buffered by capacitor bank **404** before entering into a step down transformer **408**. Step down transformer **408** reduces the voltage so that the voltage can safely be introduced into battery **410**, which is connected to ground **412** at the battery's other pole. Those of ordinary skill in the art readily recognize a variety of batteries that may work in this capacity.

[0035] In FIG. **4**C, DC IN **402** is fed into an adjustable rheostat **414**, which is controlled by the controller so that the DC OUT **416** falls within a specified range.

[0036] FIG. **5** illustrates an adjusting apparatus **500** that enables adjustment of height of the electricity collecting windsock arrangement **100** in accordance with one implementation. As per one implementation, the height of the electricity collecting windsock **102** can be adjusted using a winch motor **502** and a spool **504**. The winch motor **502** and the spool **504** can release or withdraw the tether **112** to adjust the height of the electricity collecting windsock **102** that is connected to the tether **112**. In one implementation, this release and the withdrawal may be performed manually. In another implementation, this release and the withdrawal may be performed automatically based on information obtained from a sensor system that measures atmospheric electrical energy being collected per unit time. If the sensor indicates that a current flow is diminishing, then the tether **112** is released/extended from the spool **504** to increase the altitude of the electricity collecting windsock **102** such that more static charge from the atmosphere is gathered. If the sensor indicates that collected atmospheric electrical energy exceeds a preset level per unit time, the tether **112** is withdrawn onto the spool **504** to decrease the static charge being collected from the atmosphere.

[0037] FIG. **6** is a process flow diagram illustrating aspects of a method consistent with implementations of the current subject matter. At step **602**, the functioning of the electricity collecting windsock arrangement **100** depends on whether atmospheric conditions are windy. If the atmospheric conditions are windy, the wind **116** stretches/extends outward the electricity collecting windsock **102**—Step **604**. Next, it is determined whether the atmospheric electrical energy (atmospheric current) that is collected is in a predetermined range—Step **606**. If the collected atmospheric electrical energy is in the predetermined range, the flow goes back to step **604**. If the current is not in the predetermined range, the height of the electricity collecting windsock **102** may be adjusted using adjusting apparatus **500**, such as the winch motor **502** and spool **504**. One skilled in the art understands that other implementations may include any other adjusting apparatus **500**, such as a pulley, a wheel mechanism, or the like.

[0038] The implementations set forth in the foregoing description do not represent all implementations consistent with the subject matter described herein. Instead, they are merely some examples consistent with aspects related to the described subject matter. Although a few variations have been described in detail herein, other modifications or additions are possible. In particular, further features and/or variations can be provided in addition to those set forth herein. For example, the implementations described above can be directed to various combinations and sub-combinations of the disclosed features and/or combinations and sub-combinations of one or more features further to those disclosed herein. In addition, the logic flows depicted in the accompanying figures and/or described herein do not necessarily require the particular order shown, or sequential order, to achieve desirable results. The scope of the following claims may include other implementations or embodiments.

What is claimed is:

1. An electricity collection apparatus comprising:

a tether; and

a windsock formed of an insulation material with a metal deposited on at least a portion of the insulation material, the metal of the windsock being electrically connected to the tether, the windsock to extend in a direction of ambient wind to provide a surface area based on the ambient wind, the surface area providing the metal to collect electrical energy from the ambient wind, the collected electrical energy being transferred to the tether.

2. The apparatus in accordance with claim **1**, wherein the metal is deposited on at least one of opposite sides of the insulation material.

3. The apparatus in accordance with claim **2**, wherein the metal is a metal selected from a group of metals comprising gold, silver, copper and aluminum.

4. The apparatus in accordance with claim **1**, wherein the insulation material is a polyester film.

5. The apparatus in accordance with claim **1**, wherein the transferred electrical energy at the tether is further transferred from the tether to an electricity storage device.

6. The apparatus in accordance with claim **1**, wherein the metal comprises conductors that are light-weight thereby allowing payload requirements for adjusting the windsock to an optimum location to be within a predetermined value, the optimum location comprising a height of the windsock from ground level.

7. The apparatus in accordance with claim **6**, wherein the deposited metal conductors form a pattern that maximizes the collection of the electrical energy at the optimum location.

8. An electricity collection apparatus comprising:

a windsock formed of an insulation material having a metal deposited on at least a portion of the insulation material, the windsock to extend in a direction of ambient wind to provide a surface area based on the ambient wind, the surface area providing the metal to collect electrical energy from the ambient wind; and

an electrically conductive tether connected with windsock to anchor the windsock in the direction of the ambient wind, the electrically conductive tether being electrically connected to the metal of the insulation material, the collected electrical energy being transferred to the tether.

9. The apparatus in accordance with claim **8**, wherein the metal is deposited on at least one of opposite sides of the insulation material.

10. The apparatus in accordance with claim **9**, wherein the metal is a metal selected from a group of metals comprising gold, silver, copper and aluminum.

11. The apparatus in accordance with claim **8**, wherein the insulation material is a polyester film.

12. The apparatus in accordance with claim **8**, wherein the transferred electrical energy at the tether is further transferred from the tether to an electricity storage device.

13. The apparatus in accordance with claim **8**, wherein the metal comprises conductors that are light-weight thereby allowing payload requirements for adjusting the windsock to an optimum location to be within a predetermined value, the optimum location comprising a height of the windsock from ground level.

14. The apparatus in accordance with claim **13**, wherein the metal conductors form a pattern that maximizes the collection of the electrical energy at the optimum location.

15. An electricity collection apparatus comprising:

a windsock formed of an insulation material the windsock to extend in a direction of ambient wind to provide a surface area based on the ambient wind;

one or more electrical conductors provided on at least a portion of the insulation material to collect electrical energy from the ambient wind; and

an electrically conductive tether connected with windsock to anchor the windsock in the direction of the ambient wind, the electrically conductive tether being electrically connected to the one or more electrical conductors provided on at least a portion of the insulation material to transfer the collected electrical energy from the one or more electrical conductors to an electrical storage.

(57) **ABSTRACT**

An antenna for the collection of atmospheric static electricity in which an electrically conductive hub is suspended from a balloon or blimp via a tether. The hub is either solid or uses a spoke/arm arrangement. A number of rods extend from the hub enhance the collection of atmospheric static electricity. The collected atmospheric electricity is conducted from the rods to an electrical connection where the electricity is conducted to earth via a conductive line.

FIG. 12

ATMOSPHERIC STATIC ELECTRICITY COLLECTOR

BACKGROUND OF THE INVENTION

[0001] This invention relates to the production of electrical energy and more particularly to The collection of static electricity from the atmosphere.

[0002] This is a continuation in part of U.S. patent application Ser. No. 12/218,297, filed on Jul. 14, 2008, and entitled, "Atmospheric Electrical Generator".

[0003] Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

[0004] Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

[0005] Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

[0006] It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

[0007] While lightning has, attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

[0008] It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

[0009] The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to gamer electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0010] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

[0011] The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0012] The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

[0013] Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

[0014] The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

[0015] The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

[0016] In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

[0017] In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity,

[0018] A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metalic base unit.

[0019] The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

[0020] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

[0021] A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor,

[0022] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

[0023] The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0024] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0025] This preset range is established either in the base programming of the controller or is established by an operator of the system.

[0026] As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0027] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0028] An aspect of the present invention is the use of an antenna which are used to collect the atmospheric static electricity. The antenna is shaped as a hub which is suspended from the blimp/balloon. The hub is ideally spoked shaped although an alternative embodiment uses a solid hub.

[0029] A number of rods extend from the hub so as collect atmospheric static electricity. These rods are ideally rounded at the ends to enhance the attraction of the atmospheric static electricity.

[0030] The collected atmospheric electricity is conducted from the rods to an electrical connection on the hub where the electricity is conducted to a power plant on earth such as described above.

[0031] The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

[0032] FIG. **1** diagrams the preferred embodiment of the invention.

[0033] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0034] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0035] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0036] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0037] FIGS. **6**A and **613** illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0038] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0039] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0040] FIGS. **9**A and **9**B are side views and top views of an embodiment of the antenna used to collected atmospheric electricity.

[0041] FIG. **10** is a top view of an alternative embodiment of the antenna of this invention.

[0042] FIG. **11** is a side view of yet another alternative embodiment of the antenna used to collect atmospheric electricity.

[0043] FIG. **12** is the preferred embodiment of the antenna of this invention.

DRAWINGS IN DETAIL

[0044] FIG. **1** diagrams the preferred embodiment of the invention.

[0045] Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A , extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

[0046] Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

[0047] In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

[0048] The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

[0049] Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

[0050] In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metalic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

[0051] The electrical current through conductor **6** is measured using sensor **8**.

[0052] In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

[0053] Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

[0054] The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

[0055] In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

[0056] In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

[0057] In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

[0058] There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mar. 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

[0059] In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

[0060] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0061] Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

[0062] Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

[0063] By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

[0064] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0065] Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

[0066] When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. lithe current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

[0067] If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0068] If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0069] In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

[0070] As noted earlier, some embodiments of the invention monitor the voltage instead of the current

[0071] FIGS. **4**A, **413**, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0072] By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0073] Referencing FIG. **4**A, Direct Current In (DC INT) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

[0074] Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

[0075] FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

[0076] Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27; 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

[0077] In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

[0078] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0079] This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

[0080] The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

[0081] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0082] This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

[0083] An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

[0084] Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

[0085] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0086] In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

[0087] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0088] Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

[0089] Conductive lead **82** is positioned proximate to balloon **80**.

[0090] In FIG. **8**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

[0091] FIGS. **9**A and **9**B are side views and top views of an embodiment of the antenna used to collected atmospheric electricity.

[0092] Blimp **90** supports antenna **92** via tether **91** which is attached to antenna **92** by connection **94**. In this embodiment, antenna **92** is made of electrically conductive material and is ideally light in weight to lessen the payload requirements on blimp **90**.

[0093] Encircling antenna **92** and extending therefrom are rods **93** which are rounded at their distal ends so as to enhance attraction of the atmospheric static electricity. The static electricity is communicated to connection **96** and then to electrical line **95** which communicates the electricity to the ground based station (not shown) as described above.

[0094] FIG. **10** is a top view of an alternative embodiment of the antenna of this invention.

[0095] In this embodiment of the antenna a central hub **101** has the blimp connection **104** (capable of receiving the tether to the blimp) secured thereto. In this illustration, four arms **102**A, **102**B, **102**C, and **102**D extend from hub **101**. Hub **101**, and arms **102**A, **10213**, **102**C, and **1020** are all electrically conductive in this embodiment.

[0096] At the end of each arm are rods **103** which are used to enhance the collection of the atmospheric static electricity.

[0097] Although this embodiment illustrates four arms, the invention is not intended to be limited to four arms, rather, any number of arms may be used and the number of rods extending from the distal ends of the arms also varies.

[0098] FIG. **11** is a side view of yet another alternative embodiment of the antenna used to collect atmospheric electricity.

[0099] In this embodiment, several tethers **112**A, **11213**, and **1120**, are used to secure the antenna **113** to the blimp **111**. This arrangement of several tethers provides heightened stability of the antenna by reducing the affects wind will have on the antenna.

[0100] FIG. **12** is the preferred embodiment of the antenna of this invention.

[0101] In this embodiment of the antenna, arms **122**A, **122**B, and **122**C extend from a central hum and are electrically connected to rim **124**. Tether connectors **123**A, **123**B, and **123**C, are used to secure the antenna to the blimp or balloon.

[0102] Rods **125** extend from rim **124** to increase the collection of the static charges in the atmosphere.

[0103] It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

1-16. (canceled)

17. A system for collection of atmospheric static electricity comprising:

a balloon;

a hub that is electrically conductive and connected to the balloon by a tether, the hub having two or more arms that are electrically conductive, a first end of each of the two or more arms electrically connected to the hub, the hub further having a plurality of rods, a first end of each of the rods being electrically connected to a second end of at least one of the two or more arms;

a winch motor having a spool of conductive line, one end of the conductive line secured to the hub, a portion of the conductive line and the hub collecting electricity in the atmosphere, the winch motor selectively extending or withdrawing the conductive line from the spool;

a conductor having a first end electrically connected to the conductive line and a second end electrically connected to a load being powered by collected electricity from the conductive line;

an electrical flow sensor monitoring electrical flow through the conductor and generating an electrical flow indicia indicative of the electrical flow in the conductor; and

a controller to operate the winch motor to maintain the electrical flow indicia within a selected operating range.

18. The system according to claim **17**, wherein each of the plurality of rods has a rounded second end.

19. The system according to claim **18**, wherein at least two rods are attached to the second end of each of the two or more arms.

20. The system according to claim **17**, further comprising an electrically conductive rim connected to a second end of the two or more arms.

21. The system according to claim **20**, wherein at least a portion of the two or more electrically conductive arms are connected substantially at right angles to an exterior of the electrically conductive rim.

22. A system for collection of atmospheric static electricity comprising:

two or more arms that are electrically conductive;

a plurality of rods, each of the plurality of rods being electrically connected to at least one of the two or more arms; and

a balloon tether connected between a balloon and the two or more arms;

a winch motor that extends or withdraws a spool of conductive line, one end of the conductive line being secured to the two or more arms, an extended portion of the conductive line and the two or more arms being adapted to collect electricity in the atmosphere;

a conductor having a first end electrically connected to the conductive line and a second end electrically connected to a load being powered by collected electricity from the conductive line;

an electrical flow sensor monitoring electrical flow through the conductor and generating an electrical flow indicia indicative of the electrical flow in the conductor; and

a controller to operate the winch motor to maintain the electrical flow indicia within a selected operating range.

23. The system according to claim **22**, wherein each of the plurality of rods has a rounded end distal from the electrically conductive arm.

24. The system according to claim **23**, further including a balloon tether connection secured to the first end of the two or more arms.

25. The system according to claim **24**, further including an electrical connection secured to the first end of each of the two or more arms.

26. The system according to claim **25**, wherein the at least two rods attached to the two or more arms includes three or more rods.

27. The system according to claim **25**, further including an electrically conductive rim connected to a second end of the two or more arms.

28. The system according to claim **27**, wherein the plurality of arms are electrically connected to the electrically conductive rim.

29. The system according to claim **28**, wherein at least a portion of the plurality of rods are connected to an exterior of the electrically conductive rim substantially at right angles thereto.

30. A system for the collection of atmospheric static electricity comprising:

an electrically conductive body;

a balloon tether connected to a first side of the electrically conductive body and to a balloon; and

an electrical connection connected to a second side of the electrically conductive body;

a winch motor that selectively extends or withdraws a spool of conductive line, one end of the conductive line secured to the electrical connection, a portion of the conductive line and the electrically conductive body collecting electricity in the atmosphere, the winch motor selectively extending or withdrawing the conductive line from the spool;

a conductor having a first end electrically connected to the conductive line and a second end electrically connected to a load being powered by collected electricity from the conductive line;

an electrical flow sensor monitoring electrical flow through the conductor and generating an electrical flow indicia indicative of the electrical flow in the conductor; and

a controller receiving the electrical flow indicia and selectively operating the winch motor such that the electrical flow indicia remains within a selected operating range.

31. The system according to claim **30**, wherein the electrically conductive body comprises:

an electrically conductive hub;

at least three electrically conductive arms, each of the arms connected at a first end to the hub; and

an electrically conductive rim connected to the second end of each of the at least three arms.

32. The system according to claim **31**, further comprising a plurality of electrically conductive rods, a first end of each of the rods connected to the rim and extending therefrom substantially at rights angles thereto.

(57) ABSTRACT

The system and apparatus of one or more embodiments of the present invention extracts, conditions, and conveys electric power from the earth ionosphere cavity through the integrated and collaborative operation of the system and apparatus consisting of a capacitively-coupled insulated elevated terminal (coupled capacitor upper plate), an evacuated spark gap, an integrated step-down transformer and resonant capacitor, and a ground terminal (coupled capacitor lower plate). The architecture governing exemplary embodiments of the system and apparatus of the present invention emulates the natural architecture governing the interaction of living trees with the electrical energy resident in the earth ionosphere cavity. The implementation of such exemplary embodiments of the present invention utilizes standard and customized components appropriate for their function within the system and apparatus.

The extracted electric power from the earth ionosphere cavity manifests in the form of broadband electromagnetic waves in the 0 to 200 Hz frequency range. Electric energy from these waves produce magnetic fields inside the integrated step-down transformer which are added together by the primary coil of the integrated step-down transformer, and delivered as 60 Hz 120/240 VAC to an electric load via the secondary coil of the integrated step-down transformer resonating at 60 Hz due to the influence of the integrated resonant capacitor.

The system and apparatus of exemplary embodiments of the present invention extracts, conditions, and conveys ionosphere cavity-resident electric power in alternating current and direct current realms.

FIG. 2

METHOD AND APPARATUS FOR EXTRACTING AND CONVEYING ELECTRICAL ENERGY FROM THE EARTH'S IONOSPHERE CAVITY

[0001] This application claims benefit of U.S. Provisional Application No. 61/889894, filed 11 Oct. 2013, titled, "Method and Apparatus for Extracting and Conveying Electrical Energy From the Earth's Ionosphere Cavity," the disclosure of which is incorporated herein by reference in its entirety.

BACKGROUND OF THE INVENTION

[0002] A portion of the disclosure of this patent document contains material which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by any-one of the patent document or the patent disclosure, as it appears in the Patent and Trademark Office patent file or records, but otherwise reserves all copyright whatsoever.

[0003] The invention is an apparatus and methodology for extracting electric power manifesting as a broadband collection of electric field oscillations in the 0 to 200 Hz frequency range within the Earth's ionosphere cavity, through the use of an elevated biased hemispherical or other curved surface capacitor coupling the ionosphere cavity and Earth, and then conveying this electrical energy at the proper frequency, amperage, and voltage to existing homes and buildings where it is delivered for consumption over existing home or building wiring.

DESCRIPTION OF THE RELATED ART

[0004] The current state of the art in this field is focused on the bending of radio frequency waves in the Earth's ionosphere cavity for the purpose of distorting (through reflection) the resident cavity's magnetic field to physically direct the stimulating electrical energy to targeted locations within the Earth's ionosphere cavity and/or coordinates on the Earth's surface at specific energy levels appropriate to specific applications. The regenerative feedback was done by Sutton's active antenna.

[0005] Nikola Tesla attempted to transmit wireless power in the "natural medium"; however, Tesla bad no description of a device to receive natural oscillations as described in the present disclosure.

[0006] There is no known prior art in the field of electric energy extraction from the ionosphere cavity and conveyance to other terminals within the cavity for delivery of usable electric power.

SUMMARY OF THE INVENTION

[0007] In one exemplary embodiment of the present invention, a properly-scaled electric power extraction/conveyance apparatus is installed at a typical consumer residential home to deliver 60 Hz 120/240 VAC electric power, sufficient to convey the equivalent of 5 kW of continuous electricity, to the home's existing electric service entry component to power electrical appliances in the home over existing home electric wiring.

[0008] In another exemplary embodiment of the present invention, a properly-scaled electric power extraction/conveyance apparatus is installed at an appropriate location within an industrial park or neighborhood to deliver 60 Hz 120/240 V AC electric power, sufficient to convey the equivalent of 300 kW of continuous electricity, to the service entry components of industrial buildings or neighborhood homes to power electrical devices and appliances over existing building or home electric wiring.

[0009] Alternative exemplary embodiments of the present invention will extract direct current electric power from the Earth ionosphere cavity, generated by the earth's rotating magnetosphere, and convey in the form of conditioned direct current to direct current load sources, or convert to alternating current and convey in the form of conditioned alternating current to alternating current load sources.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] A disclosure embodiments of the present invention, is set forth more particularly in the remainder of the specification, which makes reference to the accompanying figures, in which:

[0011] FIG. **1** provides an example of an electric power extraction and conveyance apparatus for one residential-scale embodiment of the present invention. Certain additional example embodiments of the present invention utilize similar fundamental technologies, but differ in the scale (size) of the components and characteristics of the electricity conveyed for consumption; and

[0012] FIG. **2** is a schematic illustration of ground terminals for use with embodiments of the present invention.

DETAILED DESCRIPTION

[0013] Applicant has discovered that trees extract and use electric power from the Earth ionosphere cavity. The present invention emulates the architecture of electric power extraction and usage methodology inherent in the natural operation of living trees, but uses standard and customized components, common in the field, for its implementation. The natural electric power extraction and use of electric power by trees leverages the shape and physical composition of trees as instances of large electrical capacitors coupled to the ionosphere cavity. The canopy of trees (upper limbs and leaf structures) emulates the upper plates of a coupled capacitor, the trunks of trees emulate a combined dielectric and resonant transformer/capacitor, and the root systems of trees emulate ground terminals (lower coupled capacitor plates). The extraction of electric power from the ionosphere cavity by trees is in the form of ultra-low frequency broadband waves (oscillations) in the frequency range of 0.1 to 14 Hertz (ULF). Inherent tree physical composition and control structure (i.e., DNA/RNA) govern the use of the extracted electric power to accomplish tree growth, seasonal metabolic adjustments, and reproductive processes. Any excess extracted electric power by trees is returned to the ionosphere cavity. The present invention is an exemplary instance of this same natural architecture using standard and customized components that facilitate extraction and conveyance of ionosphere cavity-resident broadband electric power at useful scales sufficient to provide continuous electrical power for electrical devices used by people.

[0014] One preferred exemplary embodiment of the present invention is in the form shown in Drawing **1** above and will deliver continuous 60 Hz 120/240 V AC electric power to consumer residences (and other structures with similar electricity conditioning and consumption requirements) equivalent to electric power capacity of 5 kilowatts.

[0015] A secondary exemplary embodiment of the present invention is also in the form shown in FIG. **1**, appropriately scaled for larger electrical power demands and related conveyance capacity, and will deliver continuous 60 Hz 120/240 V AC electric power to larger buildings or electrical distribution facilities for commercial office parks with electric power capacity of 300 kilowatts.

[0016] A third exemplary embodiment of the present invention is also in the form shown in FIG. **1**, appropriately scaled for larger electrical power capacity, and will deliver continuous 60 Hz 120/240 VAC electric power to utility substations with electric power capacity of 30,000 kilowatts (or higher).

[0017] The following system, power sources, and component descriptions provide additional details of the present invention in various embodiments.

[0018] Earth's ionosphere cavity (**10**) is a reservoir of continuously-generated electrical energy (E-Field) in both direct current (DC) and alternating current (AC) realms. The DC electric energy is created by the constant rotation of the Earth's magnetosphere exposed to the solar wind. Earth's perpetually moving magnetic fields create the DC electric power in the ionosphere cavity E-Field per the equations in James Clerk Maxwell's fundamental theory of electromagnetism. AC electrical energy in the ionosphere cavity is generated from the persistent E-Field disturbances (i. e., oscillations) caused by lightning discharges. The present invention includes the direct extraction of AC electric power from the ionosphere cavity, and the direct extraction of DC electric power from the ionosphere cavity which is converted to AC electric power before conveyance. Optional operational configurations of the present invention will also enable conveyance of extracted DC electric power for potential scenarios where the conveyance of conditioned DC electricity is required.

[0019] Electric-field oscillations (**22**) are induced by lightning and encapsulated in the earth-ionosphere cavity, creating a continuous source of renewable electrical energy. The frequency of lightning occurrences in the ionosphere cavity averages thirty (30) strikes per second, with each strike representing approximately one (1) terawatt (TW) of instantaneous energy. Assuming an average energy dissipation rate for each lightning strike of fifteen (15) microseconds (μsec), i. e., the time involved for one (1) terawatt of instantaneous energy to dissipate to zero (0) energy, these lightning-induced electric field oscillations are sufficient to provide 4,500 times the entire electric energy consumption on planet Earth at the projected consumption rate for the year 2100 (55.3 TWh annually). Lightning-induced E-Field oscillations vary between 0.1 and 14 Hertz with wavelengths exceeding the practicality of an electromagnetic antenna for collecting the energy. The present invention utilizes capacitive coupling to overcome this obstacle.

[0020] An insulated upper capacitor plate (terminal) (12) elevated above the influence of the ground floor collects E-Field oscillations from the ionosphere cavity. This insulated elevated terminal, capacitively-coupled to the E-Field bounded by the earth-ionosphere cavity, is arranged in a surface of large radii of curvature, supporting maximum surface connection to the E-Field without leaking the high voltage charge applied to the elevated terminal. The capacitance and resistance of the elevated terminal are responsive to the reception of broadband electric-field frequencies in the 0 to 200 hertz range. The elevated terminal is subject to high voltage alternating current biasing used to collect electric-field oscillations generated by lightning impulses in the earth-ionosphere cavity.

[0021] An evacuated spark gap (**24**) connected to the elevated terminal (**12**) prevents electrical discharge occurring between the elevated terminal and the ionosphere cavity. As the high voltage alternating current approaches peak voltage the spark gap energizes and a large voltage is applied to the step-down transformer primary coil (**16**). The high voltage pumps high current from the ground terminal (**14**, **26**) converting the electric-field to a magnetic field within the transformer (**16**). The step-down transformer is connected to a 60 hertz resonant capacitor (**18**), the secondary side of the transformer resonating at 60 hertz will supply a 60 hertz 120/240 VAC power to the load. Filter circuits will condition the power. The evacuated spark gap function may be accomplished by solid state circuitry in the implementation of the present invention.

[0022] The resonant transformer (**16**) is integrated with a parallel resonant capacitor across the transformer where the integrated combination resonates at 60 hertz supplying power to the electricity consuming structure (home or business). Various step-down transformers (**28**) are utilized to condition the conveyed electricity to accommodate the requirements of the receiving station for various embodiments of the present invention.

[0023] Ground (**26**) is the source of electric current for the present invention. A ground terminal, connected to the soil, is arranged in a surface of large radii of curvature to permit instantaneous sourcing of high currents from earth ground without temperature and voltage rise inhibiting the ground terminal collection of current. The capacitance and resistance of the ground terminal to earth is minimized to promote on demand current sourcing. Drawing **2** illustrates an exemplary apparatus of the present invention that optimizes ground connection quality by maximizing the penetration extent and resulting surface area of the ground terminal's extension into the soil.

[0024] Step-down transformers (**28**) are scaled to transform the electrical current and voltage into structured and conditioned electricity that is compatible with the electric power needs of the load sources for various embodiments of the present invention.

[0025] A mechanical nut (**40**) solidly attached to shaft **44** to facilitate extension, when turned, of large gauge copper wire extrusions (**46**).

[0026] A downward pointed anchor flat shaft (**42**) attached to the bezel **50** via a T-slot in bezel.

[0027] A copper (or other highly-conductive metal) spool base (**44**) sourcing "X" independently attached large gauge pointed copper wires (**46**) of length "Y", where "X" is equal to the number of escape portals in bezel (**50**), and "Y" is the length determined to yield optimum surface area of wires of type **46** for high quality connectivity to soil. The spool can freely rotate inside the bezel (**48**) and emulates the primary root structure of a living tree.

[0028] Sharpened large gauge (reinforced) copper wires (**46**), quantity "X", of length "Y" emulating the root structure of living trees.

[0029] Threaded bezel (spool-housing sleeve) (**48**) with drilled escape portal holes with end of copper wires (**46**) protruding through holes ½ inch.

[0030] Bezel anchor slots (**50**) of twice the height of anchor flat shafts (**42**) and T-slotted to accommodate anchor flat shafts.

[0031] Extended pointed end (**52**) of inner spool base shaft.

[0032] Escape portals (**54**) in bezel to allow for large gauge copper wire (**46**) extension into soil.

[0033] Connector port (**56**) for connection to ground terminal (**14**) in Drawing **1**.

[0034] Bezel threads (**58**).

[0035] Various embodiments of the present invention will include one or more of the following characteristics in various combinations. These descriptions are provided for purposes of example. Not all of the following characteristics will be required for any given exemplary embodiment.

[0036] Characteristic 1, The form (shape), physical composition, size, insulation, location altitude, discharge capacitive threshold and discharge rate, and the strength of AC or DC biasing applied to the (CUP) upper coupled capacitor plate (**12**: elevated terminal) all form an integrated whole, the purpose of which is to extract and temporarily store DC or AC electric power from the Earth's ionosphere cavity (**10**) at high voltage, and to trigger the energizing of the evacuated spark gap (**24**).

[0037] Characteristic 2, The elevated terminal (**12**) is capacitively coupled to the E-Field (**10**) bounded by the earth ionosphere cavity, and arranged in a surface of large radii of curvature, supporting maximum surface connection to the E-Field without leaking the high voltage charge applied to the elevated terminal (**12**).

[0038] Characteristic 3, The capacitance and resistance of the elevated terminal (**12**) are responsive to the reception of broadband electric-field frequencies in the 0 to 200 hertz range.

[0039] Characteristic 4, The elevated terminal (**12**) is subject to high voltage alternating current biasing used to collect E-Field oscillations generated by lightning impulses in the earth-ionosphere cavity.

[0040] Characteristic 5, An alternative instantiation of elevated terminal (**12**) is subject to high voltage direct current biasing used to collect E-Field direct current generated by the Earth's rotating magnetosphere.

[0041] Characteristic 6, The evacuated spark gap (**24**) may be in the form of a cohesive physical spark ignition or an operational emulation of this function through solid state circuitry.

[0042] Characteristic 7, The evacuated spark gap (**24**) connected to the elevated terminal (**12**) prevents electrical discharge occurring between the elevated terminal and the ionosphere cavity.

[0043] Characteristic 8, The high voltage alternating current from the E-Field, induced into the elevated terminal (**12**), approaches peak voltage and causes the evacuated spark gap (**24**) to energize and a large voltage is applied to the step-down transformer primary coil (**16**).

[0044] Characteristic 9, The high voltage alternating current impulse from the elevated terminal (**12**), which causes the evacuated spark gap (**24**) to energize, manifests as alternating current on broadband frequencies between 0.1 and 200 Hz.

[0045] Characteristic 10, In an alternative instantiation of the elevated terminal (**12**) the stored high voltage direct current, which causes the evacuated spark gap (**24**) to energize, manifests as direct current on broadband frequencies between 0 and 200 Hz.

[0046] Characteristic 11, The high voltage applied to the step-down transformer primary coil (**16**) pumps high current from the ground terminal (**14**), converting the electric-field to a magnetic field within the transformer (**16**).

[0047] Characteristic 12, The high current pumped from the ground terminal (**14**), caused by high voltage applied to the step-down transformer primary coil (**16**), will attempt to normalize the field and extinguish the evacuated spark gap (**24**).

[0048] Characteristic 13, The transformer's (**16**) magnetic field expands in response to the high current electric-field inrush from the ground terminal (**14**).

[0049] Characteristic 14, The primary winding inside the step-down transformer (**16**) will add the energy from each broadband frequency together into a single magnetic field, where it will become a 60 Hz frequency at the secondary winding of the transformer (**16**).

[0050] Characteristic 15, The step-down transformer (**16**) is connected to a 60 Hertz resonant capacitor (**18**).

[0051] Characteristic 16, The secondary (coil) side of the step-down transformer (**16**), resonating at 60 hertz, will supply a 60 hertz 120/240 VAC power to the electric load.

[0052] Characteristic 17, Filter circuits within the step-down transformer will condition the power according to the electric power needs of the electric load.

[0053] Characteristic 18, Electric-field lines exist (within the Earth's ionosphere cavity) that are horizontal to the surface of the Earth and extend to heights above 30,000 feet, with voltage gradients typically 100 Volts per vertical meter.

[0054] Characteristic 19, Lightning impulses create global broadband oscillations in the Earth ionosphere cavity electric-field between 0.1 and 14 Hertz.

[0055] Characteristic 20, Rotation of the Earth's magnetosphere creates global electric field oscillations in the Earth ionosphere cavity that manifest as electromagnetic waves in the 0 to 200 Hertz frequency range.

[0056] Characteristic 21, Global broadband oscillations in the Earth ionosphere cavity electric-field can be used for wireless energy transmission without harm to people, plants, or trees.

[0057] Characteristic 22, A maximum quality ground connection is achieved by expanding the surface area of the ground connection (**48** and **44**) through extension of high-conductor large gauge copper wires (**46**) horizontally through bezel (**48**) escape portals (**54**) along depth of source spool (**44**) and bezel (**48**).

[0058] Characteristic 23, The technique described in Characteristic 22 effectively expands the diameter of the ground source spool (**44**) with regard to quality of ground connection.

[0059] Characteristic 24, Bezel threads (**58**) expand surface area of bezel (**48**) touching earth, enhancing ground connection quality.

[0060] Characteristic 25, Bezel threads (**58**) enhance ground connection quality of bezel (**48**), source spool (**44**), and high conductor large gauge copper wires (**46**) through rotational insertion and resulting friction hold v. other (direct drive) insertion methods which can result in corruption of ground hole integrity caused by imprecise angle and/or vibration during insertion.

[0061] While one or more embodiments of the present invention have been described above, it should be understood that any and all equivalent realizations of the present invention are included within the scope and spirit thereof. Thus, the embodiments presented herein are by way of example only and are not intended as limitations of the present invention. Therefore, it is contemplated that any and all such embodiments are included in the present invention.

What is claimed is:

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant transformer connected between a ground terminal disposed below the surface of the earth and an elevated terminal;

impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce current flow from the ground terminal through the primary winding of the transformer; and

a power conversion circuit connected to a secondary winding of the resonant transformer to convert electrical current flowing through the secondary winding to a desired form.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformer is below 200 Hz.

3. The power receiver of claim **1** wherein the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

4. The power receiver of claim **3** wherein the impulse generator comprises:

the upper capacitive plate;

a pair of electrodes separated by a spark gap, said electrodes connected between the upper capacitive plate and the primary winding of the resonant transformer and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

5. The power receiver of claim **1** further comprising a lower capacitive plate coupled to the ground terminal.

6. The power receiver of claim **1** wherein the resonant transformer comprises a capacitor connected in parallel with a primary winding of the resonant transformer.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

METHOD OF UTILIZING RADIANT ENERGY.

SPECIFICATION forming part of Letters Patent No. 685,958, dated November 5, 1901.

Application filed March 21, 1901. Serial No. 52,154. (No model.)

To all whom it may concern:

Be it known that I, NIKOLA TESLA, a citizen of the United States, residing at the borough of Manhattan, in the city, county, and State of New York, have invented certain new and useful Improvements in Methods of Utilizing Radiant Energy, of which the following is a specification, reference being had to the drawings accompanying and forming a part of the same.

It is well known that certain radiations—such as those of ultra-violet light, cathodic, Roentgen rays, or the like—possess the property of charging and discharging conductors of electricity, the discharge being particularly noticeable when the conductor upon which the rays impinge is negatively electrified. These radiations are generally considered to be ether vibrations of extremely small wave lengths, and in explanation of the phenomena noted it has been assumed by some authorities that they ionize or render conducting the atmosphere through which they are propagated. My own experiments and observations, however, lead me to conclusions more in accord with the theory heretofore advanced by me that sources of such radiant energy throw off with great velocity minute particles of matter which are strongly electrified, and therefore capable of charging an electrical conductor, or even if not so may at any rate discharge an electrified conductor either by carrying off bodily its charge or otherwise.

My present application is based upon a discovery which I have made that when rays or radiations of the above kind are permitted to fall upon an insulated conducting body connected to one of the terminals of a condenser, while the other terminal of the same is made by independent means to receive or to carry away electricity, a current flows into the condenser so long as the insulated body is exposed to the rays, and under the conditions hereinafter specified an indefinite accumulation of electrical energy in the condenser takes place. This energy after a suitable time interval, during which the rays are allowed to act, may manifest itself in a powerful discharge, which may be utilized for the operation or control of mechanical or electrical devices or rendered useful in many other ways.

In applying my discovery I provide a condenser, preferably of considerable electrostatic capacity, and connect one of its terminals to an insulated metal plate or other conducting body exposed to the rays or streams of radiant matter. It is very important, particularly in view of the fact that electrical energy is generally supplied at a very slow rate to the condenser, to construct the same with the greatest care. I use by preference the best quality of mica as dielectric, taking every possible precaution in insulating the armatures, so that the instrument may withstand great electrical pressures without leaking and may leave no perceptible electrification when discharging instantaneously. In practice I have found that the best results are obtained with condensers treated in the manner described in a patent granted to me February 23, 1897, No. 577,671. Obviously the above precautions should be the more rigorously observed the slower the rate of charging and the smaller the time interval during which the energy is allowed to accumulate in the condenser. The insulated plate or conducting body should present as large a surface as practicable to the rays or streams of matter, I having ascertained that the amount of energy conveyed to it per unit of time is under otherwise identical conditions proportionate to the area exposed, or nearly so. Furthermore, the surface should be clean and preferably highly polished or amalgamated. The second terminal or armature of the condenser may be connected to one of the poles of a battery or other source of electricity or to any conducting body or object whatever of such properties or so conditioned that by its means electricity of the required sign will be supplied to the terminal. A simple way of supplying positive or negative electricity to the terminal is to connect the same either to an insulated conductor, supported at some height in the atmosphere, or to a grounded conductor, the former, as is well known, furnishing positive and the latter negative electricity. As the rays or supposed streams of matter generally convey a positive charge to the first condenser-terminal, which is connect-

RADIANT ENERGY.

EXAMINER

ed to the plate or conductor above mentioned, I usually connect the second terminal of the condenser to the ground, this being the most convenient way of obtaining negative electricity, dispensing with the necessity of providing an artificial source. In order to utilize for any useful purpose the energy accumulated in the condenser, I furthermore connect to the terminals of the same a circuit including an instrument or apparatus which it is desired to operate and another instrument or device for alternately closing and opening the circuit. This latter may be any form of circuit-controller, with fixed or movable parts or electrodes, which may be actuated either by the stored energy or by independent means.

The rays or radiations which are to be utilized for the operation of the apparatus above described in general terms may be derived from a natural source, as the sun, or may be artificially produced by such means, for example, as an arc-lamp, a Roentgen tube, and the like, and they may be employed for a great variety of useful purposes.

My discovery will be more fully understood from the following detailed description and annexed drawings, to which reference is now made, and in which—

Figure 1 is a diagram showing typical forms of the devices or elements as arranged and connected in applying the method for the operation of a mechanical contrivance or instrument solely by the energy stored; and Fig. 2 is a diagrammatical representation of a modified arrangement suitable for special purposes, with a circuit-controller actuated by independent means.

Referring to Fig. 1, C is the condenser, P the insulated plate or conducting body, which is exposed to the rays, and P′ another plate or conductor, all being joined in series, as shown. The terminals T T′ of the condenser are also connected to a circuit including a receiver R, which is to be operated, and a circuit-controlling device *d*, which in this case is composed of two very thin conducting-plates *t t′*, placed in close proximity and very mobile, either by reason of extreme flexibility or owing to the charater of their support. To improve their action, they should be inclosed in a receptacle from which the air may be exhausted. The receiver R is shown as consisting of an electromagnet M, a movable armature *a*, a retractile spring *b*, and a ratchet-wheel *w*, provided with a spring-pawl *r*, which is pivoted to armature *a*, as illustrated. The apparatus being arranged as shown, it will be found that when the radiations of the sun or of any other source capable of producing the effects before described fall upon the plate P an accumulation of electrical energy in the condenser C will result. This phenomenon, I believe, is best explained as follows: The sun as well as other sources of radiant energy throw off minute particles of matter positively electrified, which, impinging upon the plate P, communicate an electrical charge to the same. The opposite terminal of the condenser being connected to the ground, which may be considered as a vast reservoir of negative electricity, a feeble current flows continuously into the condenser, and inasmuch as these supposed particles are of an inconceivably small radius or curvature, and consequently charged to a relatively very high potential, this charging of the condenser may continue, as I have found in practice, almost indefinitely, even to the point of rupturing the dielectric. Obviously whatever circuit-controller be employed it should operate to close the circuit in which it is included when the potential in the condenser has reached the desired magnitude. Thus in Fig. 2 when the electrical pressure at the terminals T T′ rises to a certain predetermined value the plates *t t′*, attracting each other, close the circuit connected to the terminals. This permits a flow of current which energizes the magnet M, causing it to draw down the armature *a* and impart a partial rotation to the ratchet-wheel *w*. As the current ceases the armature is retracted by the spring *b* without, however, moving the wheel *w*. With the stoppage of the current the plates *t t′* cease to be attracted and separate, thus restoring the circuit to its original condition.

Many useful applications of this method of utilizing the radiations emanating from the sun or other source and many ways of carrying out the same will at once suggest themselves from the above description. By way of illustration a modified arrangement is shown in Fig. 2, in which the source S of radiant energy is a special form of Roentgen tube devised by me having but one terminal *k*, generally of aluminium, in the form of half a sphere with a plain polished surface on the front side, from which the streams are thrown off. It may be excited by attaching it to one of the terminals of any generator of sufficiently-high electromotive force; but whatever apparatus be used it is important that the tube be exhausted to a high degree, as otherwise it might prove entirely ineffective. The working or discharge circuit connected to the terminals T T′ of the condenser includes in this case the primary *p* of a transformer and a circuit-controller comprising a fixed terminal or brush *t* and a movable terminal *t′* in the shape of a wheel with conducting and insulating segments which may be rotated at an arbitrary speed by any suitable means. In inductive relation to the primary wire or coil *p* is a secondary *s*, usually of a much greater number of turns, to the ends of which is connected a receiver R. The terminals of the condenser being connected as indicated, one to an insulated plate P and the other to a grounded plate P′, when the tube S is excited rays or streams of matter are emitted from the same, which convey a positive charge to the plate P and condenser-terminal T, while terminal T′ is continuously receiving negative electricity from the plate

P'. This, as before explained, results in an accumulation of electrical energy in the condenser, which goes on as long as the circuit including the primary p is interrupted. Whenever the circuit is closed, owing to the rotation of the terminal t', the stored energy is discharged through the primary p, this giving rise in the secondary s to induced currents which operate the receiver R.

It is clear from what has been stated above that if the terminal T' is connected to a plate supplying positive instead of negative electricity the rays should convey negative electricity to plate P. The source S may be any form of Roentgen or Lenard tube; but it is obvious from the theory of action that in order to be very effective the electrical impulses exciting it should be wholly or at least preponderatingly of one sign. If ordinary symmetrical alternating currents are employed, provision should be made for allowing the rays to fall upon the plate P only during those periods when they are productive of the desired result. Evidently if the radiations of the source be stopped or intercepted or their intensity varied in any manner, as by periodically interrupting or rythmically varying the current exciting the source, there will be corresponding changes in the action upon the receiver R, and thus signals may be transmitted and many other useful effects produced. Furthermore, it will be understood that any form of circuit-closer which will respond to or be set in operation when a predetermined amount of energy is stored in the condenser may be used in lieu of the device specifically described with reference to Fig. 1, and also that the special details of construction and arrangement of the several parts of the apparatus may be very greatly varied without departure from the invention.

Having described my invention, what I claim is—

1. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations, and the other armature by independent means, and discharging the condenser through a suitable receiver, as set forth.

2. The method of utilizing radiant energy, which consists in simultaneously charging a condenser by means of rays or radiations and an independent source of electrical energy, and discharging the condenser through a suitable receiver, as set forth.

3. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations, and the other by independent means, controlling the action or effect of said rays or radiations and discharging the condenser through a suitable receiver, as set forth.

4. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations and the other by independent means, varying the intensity of the said rays or radiations and periodically discharging the condenser through a suitable receiver, as set forth.

5. The method of utilizing radiant energy, which consists in directing upon an elevated conductor, connected to one of the armatures of a condenser, rays or radiations capable of positively electrifying the same, carrying off electricity from the other armature by connecting the same with the ground, and discharging the accumulated energy through a suitable receiver, as set forth.

6. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations, and the other by independent means, and effecting by the automatic discharge of the accumulated energy the operation or control of a suitable receiver, as set forth.

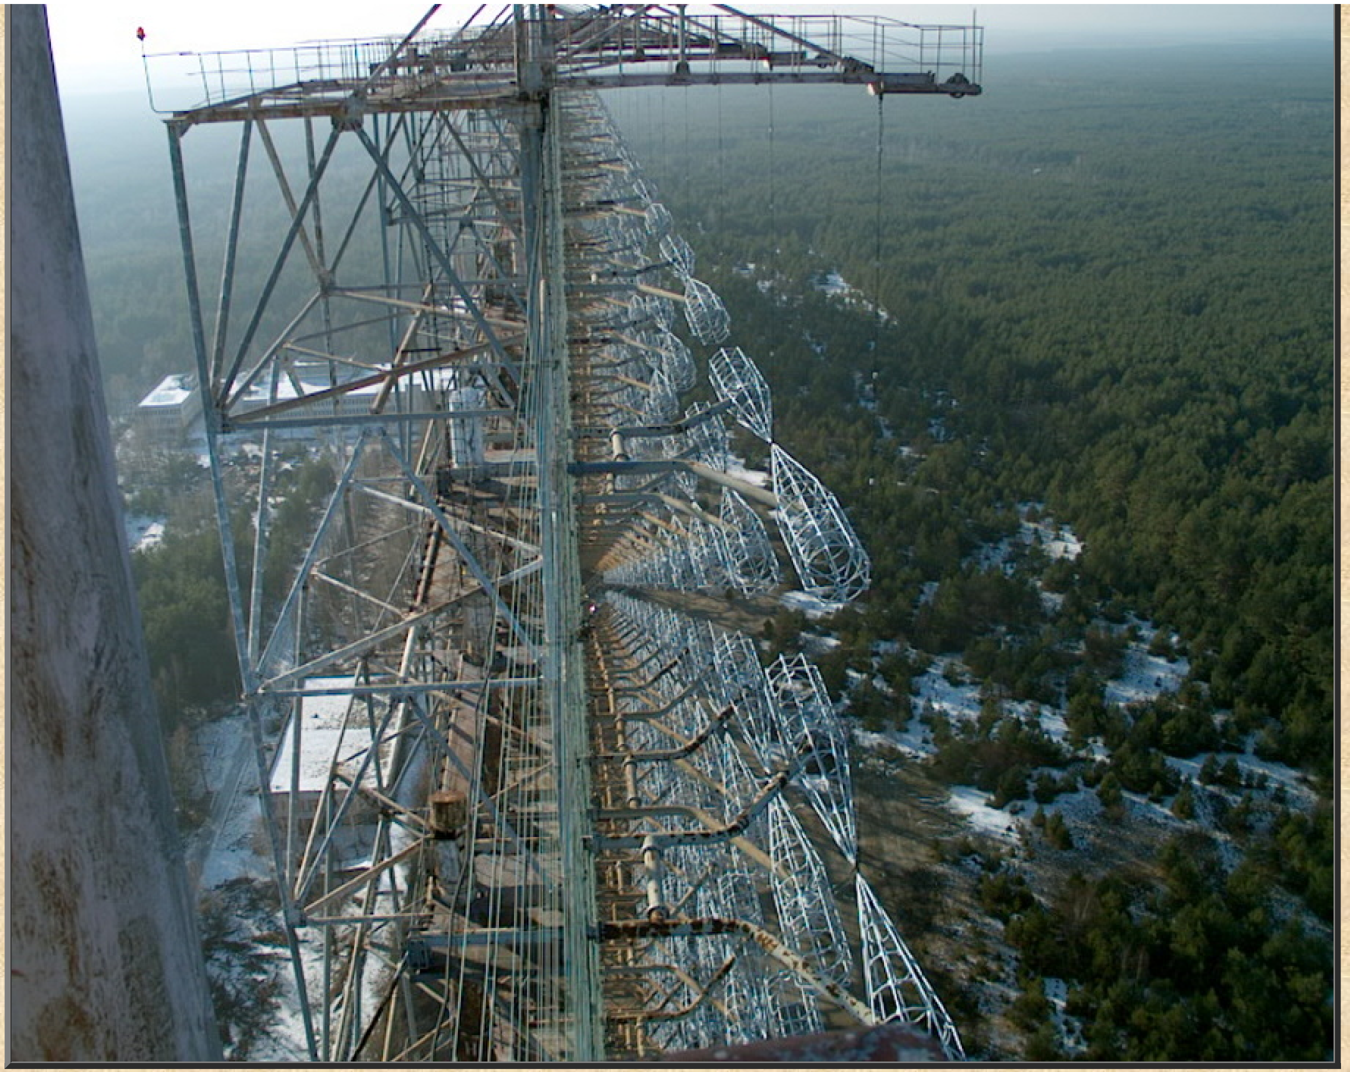
A back plane reflector of small wires can just be seen left of center, most clearly at the bottom of the image.

The Russian Woodpecker was a notorious Soviet signal that could be heard on the shortwave radio bands worldwide between July 1976 and December 1989. It sounded like a sharp, repetitive tapping noise, at 10 Hz, giving rise to the "Woodpecker" name. The random frequency hops disrupted legitimate broadcast, amateur radio, and utility transmissions and resulted in thousands of complaints by many countries worldwide.

The signal was long believed to be that of an over-the-horizon radar (OTH) system. This theory was publicly confirmed after the fall of the Soviet Union, and is now known to be the Duga-3[1] system, part of the Soviet ABM early-warning network. This was something that NATO military intelligence was well aware of all along, having photographed it and giving it the NATO reporting name Steel Yard.



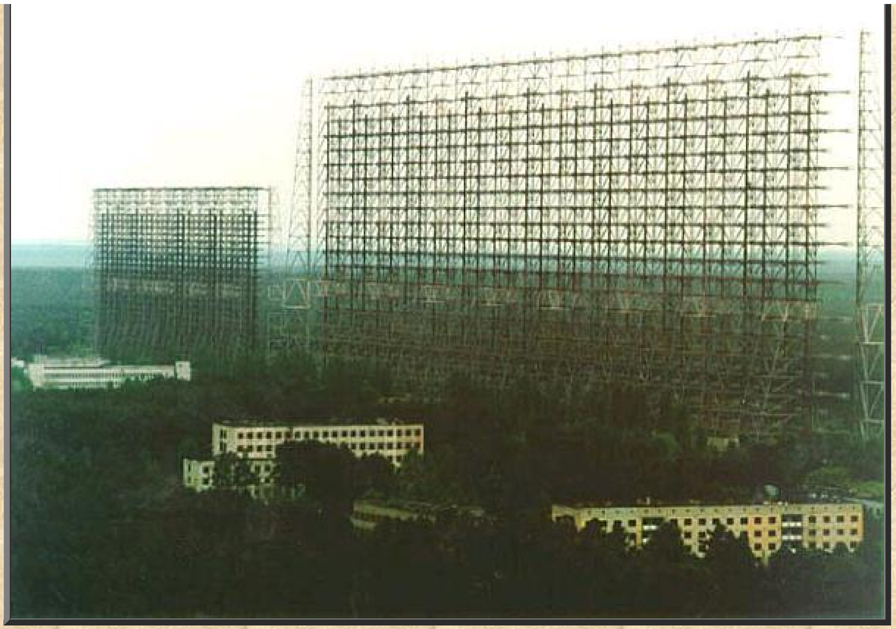
"Woodpecker" Duga radar array, Chenobyl, Ukraine by Necator

Woodpecker - Woodpecker on shortwave radio interfering with WWVH, November 2, 1984.

History

The Soviets had been working on early warning radars for their anti-ballistic missile systems through the 1960s, but most of these had been line-of-sight systems that were useful for raid analysis and interception only. None of these systems had the capability to provide early-warning of a launch, which would give the defenses time to study the attack and plan a response. At the time the Soviet early-warning satellite network was not well developed, so work started on over-the-horizon radar systems for this associated role in the late 1960s.

The first experimental system, Duga-1, was built outside Mykolaiv in the Ukraine, successfully detecting rocket launches from Baikonur Cosmodrome at 2,500 kilometers. This was followed by the prototype Duga-2, built on the same site, which was able to track launches from the far east and submarines in the Pacific Ocean as the missiles flew towards Novaya Zemlya. Both of these radars were aimed east and were fairly low power, but with the concept proven work began on an operational system. The new Duga-3 systems used a transmitter and receiver separated by about 60 km.[2]

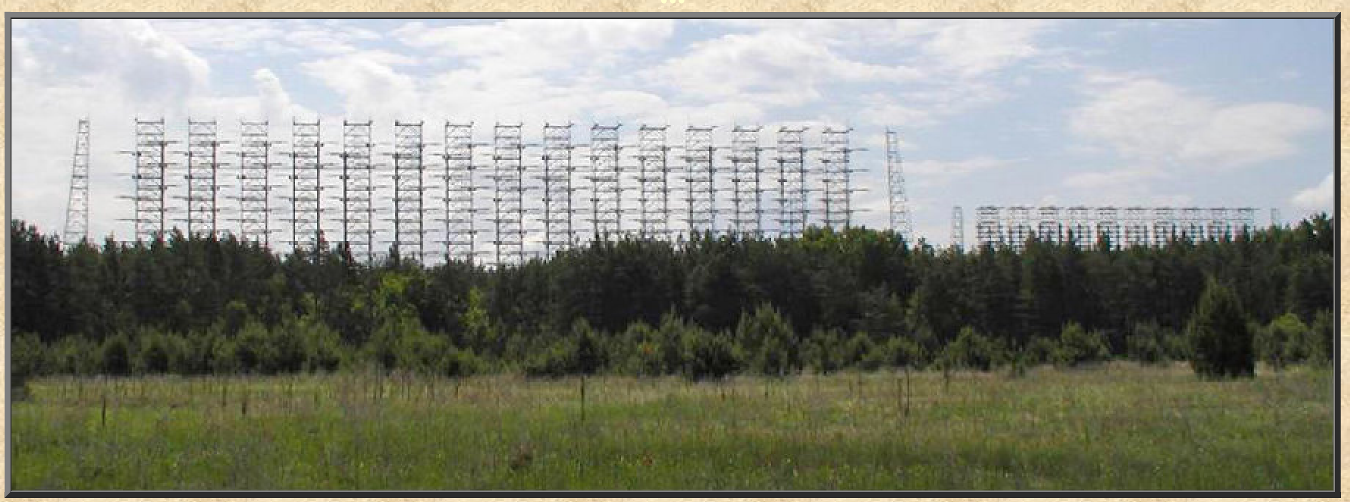


РЛС Дуга-1 Чернобыль-2 (Radar arch-1 Chernobyl-2) by DM.HANTER

Appearance

Starting in 1976 a new and powerful radio signal was detected worldwide, and quickly dubbed the Woodpecker by amateur radio operators. Transmission power on some woodpecker transmitters was estimated to be as high as 10 MW EIRP. As well as disrupting shortwave amateur radio and broadcasting it could sometimes be heard over telephone circuits due to the strength of the signals. This led to a thriving industry of "Woodpecker filters" and noise blankers.

One idea amateur radio operators used to combat this interference was to attempt to "jam" the signal by transmitting synchronized unmodulated continuous wave signals, at the same pulse rate as the offending signal. This idea was considered, but abandoned as impractical. Simple CW pulses didn't appear to have any effect. However, playing back recordings of the woodpecker transmissions sometimes caused the woodpecker transmissions to shift frequency leading to speculation that the receiving stations were able to differentiate between the "signature" waveform of the woodpecker transmissions and a simple pulsed carrier.[4]



Чорнобиль-2. Приймальні антени. (Chernobyl-2. RX antennas.) by djcrok

Identification

Triangulation quickly revealed the signals came from Ukraine. Confusion due to small differences in the reports being made from various military sources led to the site being alternatively located near Kiev, Minsk, Chernobyl, Gomel or Chernihiv. All of these reports were describing the same deployment, with the transmitter only a few kilometers southwest of Chernobyl (south of Minsk, northwest of Kiev) and the receiver about 50 km northwest of Chernobyl (just west of Chernihiv, south of Gomel). Unknown to most observers, NATO was well aware of the new radar installation, which they referred to as Steel Yard.

Even from the earliest reports it was suspected they were tests of an over-the-horizon radar., and this remained the most popular theory during the cold war. Several other theories were floated as well, including everything from jamming western broadcasts to submarine communications. The broadcast jamming theory was debunked early on when a monitoring survey showed that Radio Moscow and other pro-Soviet stations were just as badly affected by woodpecker interference as Western stations. More speculative explanations were also offered, claiming it was a system for weather control or even an attempt at mass subconscious mind control.

As more information about the signal became available, its purpose as a radar signal became increasingly obvious. In particular, its signal contained a clearly recognizable structure in each pulse, which was eventually identified as a 31-bit pseudo-random binary sequence, with a bit-width of 100 µs resulting in a 3.1 ms pulse. This sequence is usable for a 100 µs chirped pulse amplification system, giving a resolution of 15 km (10 mi) (the distance light travels in 50 µs). When a second Woodpecker appeared, this one located in eastern Russia but also pointed toward the US and covering blank spots in the first system's pattern, this conclusion became inescapable.

In 1988, the Federal Communications Commission conducted a study on the Woodpecker signal. Data analysis showed an inter-pulse period of about 90 ms, a frequency range of 7 to 19 MHz, a bandwidth of 0.02 to 0.8 MHz, and typical transmission time of 7 minutes.

- The signal was observed using three repetition rates: 10 Hz, 16 Hz and 20 Hz.
- The most common rate was 10 Hz, while the 16 Hz and 20 Hz modes were rather rare.
- The pulses transmitted by the woodpecker had a wide bandwidth, typically 40 kHz.

Пропускной пункт на территорию РЛС (Checkpoint to the territory of the radar) - by Alex Taranenko

Disappearance

Starting in the late 1980s, even as the FCC was publishing studies of the signal, the signals became less frequent, and in 1989 disappeared altogether. Although the reasons for the eventual shutdown of the Duga-3 systems have not been made public, the changing strategic balance with the fall of the cold war in the late 1980s likely had a major part to play. Another factor was the success of the US-KS early-warning satellites, which entered preliminary service in the early 1980s, and by this time had grown into a complete network. The satellite system provides immediate, direct and highly secure warnings, whereas any radar-based system is subject to jamming, and the effectiveness of OTH systems is also subject to atmospheric conditions.

According to some reports, the Komsomolsk-na-Amure installation in Siberia was taken off combat alert duty in November 1989, and some of its equipment was subsequently scrapped. Google Maps photography of the area shows that the antenna has been removed. The original Duga-3 site lies within the 30 kilometer Zone of Alienation around the Chernobyl power plant. It appears to have been permanently deactivated, since their continued maintenance did not figure in the negotiations between Russia and Ukraine over the active early warning radars at Mukachevo and Sevastopol. The antenna still stands, however, and has been used by amateurs as a transmission tower (using their own antennas) and has been extensively photographed.

Appearances in media

The Ukrainian-developed computer game S.T.A.L.K.E.R has a plot focused on the Chernobyl Nuclear Power Plant and the nuclear accident there. The game heavily features actual locations in the area, including the Duga-3 array. It is presented as the "Brain Scorcher", a wide-area mind control device which must be deactivated by the player.

GENERAL PREFACE

THIS series of small monographs is one which should commend itself to a wide field of readers.

The reader will find in these volumes an up-to-date résumé of the developments in the subject considered. The references to the standard works and to recent papers will enable him to pursue further those subjects which he finds of especial interest. The monographs should therefore be of great service to physics students who have examinations to consider, to those who are engaged in research in other branches of physics and allied sciences, and to the large number of science masters and others interested in the development of physical science who are no longer in close contact with recent work.

From a consideration of the list of authors it is clear that the reader need have no doubt of the accuracy of the general accounts found in these volumes.

ATMOSPHERIC ELECTRICITY

CHAPTER I

THE IONISATION OF THE ATMOSPHERE

THE electrical conductivity of the air, first established by Linss in the year 1887, plays an important part in all the phenomena included under the title Atmospheric Electricity. Since 1901, when Elster and Geitel and C. T. R. Wilson independently discovered that this conductivity is due to the presence of small carriers of positive and negative charge called ions, the nature and the origin of these ions have been the subject of many investigations. Two different paths have been followed, the one dealing with the number and the nature of the atmospheric ions, the other with the radiations producing them. *The two paths converge on the problem of the* ionisation-balance of the atmosphere, the manner in which an equilibrium is maintained between the rate of creation and the rate of disappearance of the ions. It is only of recent years that an answer to this problem has emerged.

The investigation of the ionisation of the air has been rendered exceptionally difficult by the number of separate factors involved and by the variation of each with local geological and meteorological conditions. Much remains to be done before the conditions governing the conductivity of even the lowest layers of the atmosphere are completely understood; observations at greater heights in the regions accessible to balloons and airships are just emerging from the difficult pioneer stage, and the very important regions of the upper air which lie beyond fifteen kilometres above the ground can at present be examined only indirectly by deductions based upon the mode of propagation of upwardly directed wireless waves and upon the variations of the earth's magnetic field.

§ 1. The Atmospheric Ions, Small and Large

A gas molecule is ionised when some external agency supplies the energy necessary to remove an electron from it, whereupon the positively charged residue of the molecule and the ejected electron, both of which under ordinary pressures very soon attach themselves to one or more uncharged molecules, form what is called an ion-pair. Such ions are known as "normal," "small," or "fast," and when found in the atmosphere have mobilities of the same order as those determined for pure dry air in laboratory experiments, about 1·5 cm./sec. in a field of gradient 1 volt per cm.

The presence in the air of minute particles of dust, of the products of combustion, and of extremely small drops of water even when the air is unsaturated, leads very often to the capture of a normal ion by one of these condensation or Aitken nuclei, as they are termed, and so to the formation of another type of ion of low mobility, ranging from ·0005 to ·0003 cm./sec., known as "large," "slow," or "Langevin" ions. Roughly speaking, one-third of the condensation nuclei present in the air is electrically neutral, the other two-thirds carry, nearly equally, positive and negative charges captured from small ions. The interplay between the large and the small ions and the uncharged nuclei is of considerable importance.

Besides these two main types of atmospheric ion, a group of "intermediate" ions whose mobilities lie between ·1 and ·01 cm./sec. has been found to be present under special meteorological conditions such as low relative humidity. While the origin of this type of ion is at present uncertain, its existence emphasises the fact *that the customary division into the two main classes,* large and small, requires refinement, and future work will no doubt proceed in the direction of dividing the ions according to their mobilities into a larger number of groups. J. Nolan and de Sachy have recently found evidence of such groups in the small and the large ion "families."[1]

It has been found that the great majority of the ions, large and small, carry a single elementary charge, either positive or negative.[2] Over land areas the large ions considerably outnumber the small ones, often in the ratio of ten to one. Thus while the numbers, n_+ and n_-, of small ions of each sign per c.c. of the air over land usually range from 300 to 1000, those of the large ions, N_+ and N_-, amount to from 1,000 to 80,000 per c.c. Since practically all the large ions are formed from the capture of small ones by nuclei, an increase in the number of these nuclei, such as is due to the fires of an industrial area, will increase the proportion of the large ions in the air at the expense of the small ions.

Over the oceans this state of affairs is reversed ; the air away from land areas is but poorly supplied with nuclei and the large ions are in the minority. The mean values of n_+ and n_- at sea lie between 500 and 700 per c.c., while N_+ and N_- are about 200 per c.c. In view of their comparative freedom from capture by nuclei, it is at first sight rather surprising that the number of small ions per c.c. in mid-ocean differs but little from the same quantity over the land, where the average values of n_+ and n_- are also about 600 per c.c. This is, however, to be explained (§ 12) by the fact that the decreased rate of disappearance of the small ions over the sea is balanced by a decrease in the rate at which they are produced.

§ 2. THE DETERMINATION OF THE NUMBER OF IONS PER C.C.

To determine the numbers of the small ions, positive and negative, per c.c. (n_+ and n_-) an arrangement known as an Ebert ion-counter is usually employed. This consists in essentials of a long earthed metal tube A (Fig. 1) on the axis of which is mounted a charged insulated rod B, connected to a quartz fibre electroscope. Air is sucked through the tube for about five minutes by means of a clock-work driven fan F and the speed of the air-stream is arranged to be slow enough for all the small ions entering A with charges opposite in sign to that on the central rod to be drawn to B before reaching the bottom of the tube. The speed of flow must at the same time be great enough to make it impossible for any appreciable number of large ions to have time to reach the rod. If v is the volume of the air sucked through in the course of the measurement (indicated by an anemometer C registering its revolutions on a dial), the quantity of electricity gathered in by the central electroscope system is ven_-, where e is the elementary charge on a single ion and the rod is supposed to have been positively charged. If then C is the capacity of the whole central system, rod and electroscope, and V and V′ are the potentials indicated by the electroscope before and after the experiment, $C(V - V') = ven_-$, an equation from which n_- can be

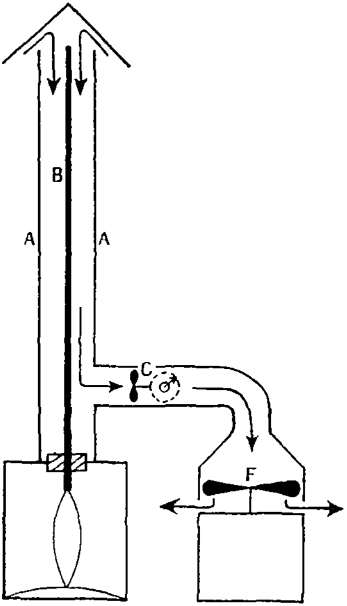

FIG. 1.—Ebert ion-counter.

found. To determine n_+, the measurement must be repeated with the rod B charged negatively.

The same method, using a longer tube, a stronger field in its interior, and a slower draught of air, and thus giving time for the capture of all the slow ions as well, can be applied to the determination of $N + n$. A combination of the two determinations then yields N_+ and N_-, the numbers of the large ions per c.c. of each sign.

The values found for n_+ and n_- are not usually the same; the ratio n_+/n_- over both land and sea has a mean value of 1·22. Although, as explained in § 30, the earth's electric field may sometimes affect the apparatus in such a way as to give a spuriously high ratio, Swann, who has made a special study of the point, concludes that when all precautions are taken a real excess of positive ions must be admitted. Probably the main factor causing this excess is the superior mobility of the small negative ion; Nolan has found that k_-/k_+ has the value 1·16. A lower mobility implies a lower velocity of thermal agitation for the positive than the negative ion, and consequently less likelihood of capture by condensation nuclei. Another contributing cause may be the Ebert effect discussed in § 38. This general excess of positive small ions does not necessarily involve a nett positive charge in the air; it is easily compensated for by a comparatively small excess in the much larger number of large negative ions.

An instrument known as the Aitken dust-counter is used to find the total number of nuclei, charged and uncharged, per c.c. It consists of a small expansion chamber filled with a sample of the air and saturated with water-vapour. The sudden movement of a piston gives an adiabatic expansion which causes drops of water to condense upon the nuclei; the resulting cloud falls upon a glass plate divided into squares and the number of droplets is counted under a microscope. Though called a dust-counter it does not record the coarser dust in the air.[3]

§ 3. The Polar Conductivities and the Ionic Mobilities

A simple relation holds between the conductivity of the air and the numbers per c.c. and the mobilities of the ions responsible for conduction. Consider a point in the atmosphere at which the electric field intensity is F and the specific conductivity, the reciprocal of the specific resistance, is λ. The conduction current, i, through unit area drawn perpendicular to the field is then equal to Fλ, for F is numerically equal to the potential difference, and $1/\lambda$ is the resistance, between the ends of a unit cube of the air. In this equation we assume that conditions are such that Ohm's law can be applied to the air. Since the current is carried by positive and negative streams of ions moving in opposite directions we may write

$$i = \mathrm{F}(\lambda_+ + \lambda_-), \quad . \quad . \quad . \quad (1)$$

where λ_+ and λ_- are called the polar conductivities.

Actually the existence of the two main types of ion, large and small, leads to the flow of four different ion-streams, two up and two down if the field is vertical, in each of which the velocity is different, being given by F × k, where k is the corresponding mobility. The total current is thus

$$i = \mathrm{F}e(n_+k_+ + n_-k_- + \mathrm{N}_+\mathrm{K}_+ + \mathrm{N}_-\mathrm{K}_-), \quad . \quad (2)$$

where k_+ and k_-, K_+ and K_-, are the mobilities of the positive and the negative ions, large and small respectively, and e is the elementary charge. From (1) and (2), separating out the oppositely moving streams,

$$\lambda_+ = (k_+n_+ + \mathrm{K}_+\mathrm{N}_+) \text{ and } \lambda_- = (k_-n_- + \mathrm{K}_-\mathrm{N}_-). \quad (3)$$

In clear country air over land, n_+ and n_- number about 600 per c.c., while N_+ and N_- are about 2000 per c.c. ; k_+ and k_- are 1·5 approximately and K_+ and K_-, ·0004. Here, therefore, the ratio of the first to the second term in each bracket above is 1100 : 1 and most of the conductivity of the air is due to the small ions. Near large towns, however, n is usually of the order of 100 per c.c. and N, on account of the heavy pollution of the atmosphere may be 50,000. Under these conditions the second term would be one-seventh of the first and the large ions would play a part in the transfer of electricity through the air.*

It is not usual to find the polar conductivities from equations (3) above, but directly, from measurements of the rate which the charge on an insulated body exposed to the free air is dissipated by the flow of ions to it. Consider a negatively charged body exposed to moving air and let σ be the density of the electrification on any portion of area dS.[1] Positive ions will move to the body, and since the field F just outside the surface is $4\pi\sigma$, the current per unit area tending to dissipate the charge will be $F\lambda_+ = 4\pi\sigma\lambda_+$. The total dissipation current, obtained by integrating over the whole exposed surface, is $4\pi\lambda_+\int\int\sigma dS$ or $4\pi\lambda_+Q$, where Q is the charge exposed to the air. Since this current represents the rate at which the body loses charge, we have $-dQ/dt = 4\pi\lambda_+Q$, a relation which provides a means of determining λ_+. A similar equation, with λ_- substituted for λ_+, holds for the case of a positively charged body.

An arrangement used for this purpose is due to Gerdien (Fig. 2); it resembles the Ebert apparatus already described, but the air-stream is now made so rapid and the field in the interior of the tube so weak, that only a very small fraction of the total number of ions passing through A has time to reach the central rod. In this case the numbers of ions per c.c. are not appreciably altered by the experiment and Ohm's Law applies.

If the potential V of the negatively charged central electroscope system is observed to rise at a rate dV/dt and if C is the total capacity of the central system, rod and electroscope, we have $-dQ/dt = -CdV/dt$. Also, if C′ is the capacity of that portion of the central system exposed to the stream of air, the rod B and its support, Q = C′V, consequently

---

* The methods used to determine ionic mobilities are described in text-books on the conduction of electricity through gases

$$-CdV/dt = 4\pi\lambda_+ C'V, \quad . \quad . \quad . \quad (4)$$

a relation from which λ_+ can be determined. A similar experiment with the rod positively charged yields λ_-. The use made of the values found for the polar conductivities and an adaptation of the Gerdien method due to Schering are described in Chapter III, § 30.

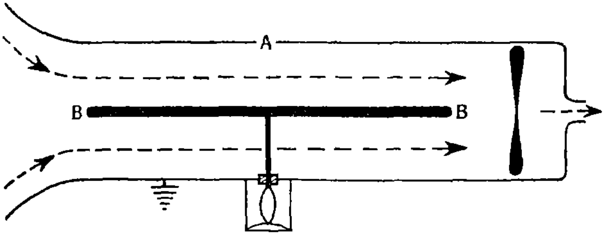

Fig. 2.—Gerdien conductivity apparatus.

§ 4. The Ionising Agencies

Three principal agencies are responsible for the ionisation of the lower atmosphere: radiations from radioactive substances in the surface of the earth, radiations from radioactive matter present in the air itself, and the penetrating radiation. For a discussion of their relative importance it is convenient to use the symbol q to represent the number of "pairs of ions produced per c.c. per second in air at N.T.P.," a quantity which will be referred to as the ionising power of the radiation. This phrase in inverted commas is usually represented by the symbol I. Thus the statement $q = 4$ I means that, at the point in question, the radiations create four pairs of ions per c.c. per second, if the medium there is air at N.T.P. The contributions of the three different agencies just mentioned to the total ionising power, q, are distinguished by the symbols q_e, q_a, and q_h.

§ 5. The Effect of Radioactive Matter in the Earth

Uranium, thorium, and their products are widely distributed through the earth's crust, whose surface layers therefore emit α, β, and γ rays into the air. Since the α rays can only emerge from a very thin layer and can only ionise the first few cms. of the air, their effect is inconsiderable. The β rays can come from greater depths and penetrate much further into the atmosphere. Calculations based upon average values for the measured concentration of radioactive matter in the earth indicate that an effect ranging from 1 I at the surface to 0·1 I at about 10 metres above it is due to these rays. The γ rays are a more important factor, for they can come from still greater depths and consequently from a still larger quantity of radioactive material. It is estimated that they produce on the average 3 I at the surface, 1·5 I at 150 metres above it, and 0·3 I at a height of 1 kilometre. The recent discovery of the γ ray activity of potassium introduces another source of ionisation, for the potassium content of the earth's crust is considerable. No very detailed survey of this question has yet been made, but measurements indicate that at a height of 10 metres the contributions of radium, thorium, and potassium to the γ ray ionisation of the air are in the ratio of 1 : 1 : 0·7, in accord with sampling of the surface content of the earth.[5] The average value for the ionising power of the earth-radiations near the ground has been found directly to lie between 2 and 10 I, which is in accord with the measurements of the radioactive content of the earth's crust. Local surface and geological conditions naturally have a marked effect upon the value of q_e at any given spot.

The radioactive content of sea-water is found to be negligible in comparison with that of soil and rocks, and over the oceans the earth-radiation effect is very small indeed.

§ 6. THE EFFECT OF RADIOACTIVE MATTER IN THE AIR

The atmosphere contains a considerable quantity of the radioactive emanations, radon and thoron, and their successive products. A wire charged negatively to a potential of a few hundred volts and exposed to the air collects an easily detectable quantity of radium A and thorium A by recoil from the disintegration of these emanations. The gases themselves arise from the decay of radium and thorium within the earth, from which they escape by diffusion, by thermal convection, and as a result of decreases in the external atmospheric pressure. The greater portion of the ionisation thus produced is due to the α rays from the emanations themselves and from their A and C products, for here, unlike the case of the radiations from the earth, there is no absorbing layer between the disintegrating atom and the air. The radioactive gases and their products are fairly evenly distributed by atmospheric turbulence through the lower air. This "air-radiation" effect can be calculated from radioactive data if the emanation content of the air is determined. The emanations may be removed from a measured volume of air by drawing it through tubes cooled with liquid air or filled with coconut charcoal. The quantity of emanation condensed or absorbed is then determined by the effect produced in an ionisation electroscope, corrected for the decay of the material during the time of the experiment. A more direct method is to fill a closed ionisation chamber first with ordinary air and then with air which has been freed by the above method from the emanations and from their products, and to determine the saturation currents in the two cases. If these are i_1 and i_2 respectively, v the volume of the vessel and e the elementary charge, the value of the air-radiation ionising power, q_a, is given by $i_1 - i_2 = q_a ve$.

The results of such measurements agree with estimates based upon observations of the average emanation content of the air in placing the air-radiation effect at about 5 I in the neighbourhood of the earth's surface. Of this about 60 per cent. is due to radon and its α ray products and the remainder to the thoron series. It varies somewhat with locality and with those meteorological conditions which determine the rate of escape of the emanations Apart from the effect of strong upward winds in elevating the richer surface layers, the emanation content of the air should decrease fairly rapidly with height. Direct information on this point is difficult to obtain, but what exists indicates that the air-radiation effect falls to less than 2 per cent. of its surface value at a height of 5 kilometres.

The effect, like that of the earth-radiation, is extremely small over the oceans, where the emanation content of the air is only about 1 per cent. of its value over land areas.

§ 7. The Effect of the Penetrating Radiation

The third factor in the ionisation of the atmosphere is a radiation of peculiar interest, whose origin and nature are still the subject of much investigation. It has a penetrating power which is considerably greater than that of the most penetrating γ rays from radioactive bodies, and it travels to the earth's surface in a downward direction, undergoing a certain amount of absorption on the way. Its ionising power at sea-level over both land and ocean areas lies between 1·5 and 2·5 I. Though these figures correctly suggest that the absolute value of the effect is not accurately known, relative observations can be made with great certainty and show that the ionising power of the radiation at a given height above sea-level is practically independent of geographical position and alters only slightly with meteorological conditions such as pressure. The ionisation due to this radiation increases rapidly with height above sea-level, rising ten-fold in the first 5 kilometres. It is discussed in greater detail in the next chapter.

§ 8. The Ionisation Inside a Closed Vessel

It is a matter of considerable difficulty to determine separately the ionising powers of the earth-radiation and of the penetrating rays. Calculations of the former must be based upon measurements of the radioactive content of the earth's crust, and these are necessarily tedious and rough. To proceed further, one must examine the ionisation produced in the air inside a sealed metal chamber under conditions which are modified from those existing in the free air by the presence of the metal walls. This involves correction to free-air conditions. A further disadvantage is that a new ionising agency is introduced, the radioactive matter in and on the inside walls. The ionising power of this "wall-effect," or the "residual ionisation" of the vessel as it is called, is a constant depending on the material of which the walls are made and the cleanliness of the inner surface. It is usually represented by the symbol q_0.

The total ionising power of all the radiations operating upon the gas in a closed vessel may be called q' and the modified effects of the three main ionising agencies q'_e, q'_a, and q'_h : we then have

$$q' = q'_e + q'_a + q'_h + q_0. \quad . \quad . \quad (5)$$

We may suppose the vessel to take the form of a sealed ionisation chamber filled with air at N.T.P. which has been freed from radioactive matter. The saturation current carried by the ions to the central collecting electrode is then given by $i = q've$, where v is the volume of the vessel and e the elementary charge on an ion.

Various methods have been employed to separate out the four terms on the right-hand side of equation (5) from one another. The most satisfactory of these begins by determining q_0. The instrument, whose form is described in the following chapter, is taken to a large snow-fed lake whose radioactive content, like that of the sea, is negligible. When it is sunk to the depth of a few feet in such a lake, the effects of earth and air-radiations are non-existent and equation (5) becomes $q' = q'_h + q_0$; on lowering the vessel still further, q'_h diminishes as the penetrating radiation becomes absorbed in the increasing thickness of water, and it is possible to reach depths at which the saturation current is practically constant and unaffected by further sinking of the instrument. At this stage $q' = q_0$, and the residual ionisation is determined. By combining this observation with that made close to the surface of the lake, q'_h may be found.

Since the effects of the penetrating radiation and of the walls of the vessel are both independent of local conditions other than height above sea-level, they remain the same when the instrument is transported to a site on land at the same level. A measurement of the saturation current in the chamber under land conditions gives q' as stated by equation (5), and hence the sum of the earth and air effects, q'_e and q'_a can be found In actual practice the air-radiation effect within a closed vessel is extremely small: the walls exclude α and β rays coming from outside and reduce q'_a to the ionising power of the γ rays emitted by the B and C products of the radioactive emanations. This amounts to but 4 per cent. of the effect produced by the air-radiation in the free atmosphere, in the case of a vessel with steel walls a few millimetres thick. It is therefore sufficient to determine the air-radiation effect, q'_a, by calculation based upon a knowledge of the emanation content of the air and of the nature of the walls of the vessel. The fourth factor, the effect of the earth-radiation, q'_e, is then obtained by substitution in equation (5).

To pass from these closed vessel determinations of the effect of the radioactive matter in the earth to the effect to be expected in the free air, experiments may be made with screens of different thicknesses placed around the ionisation chamber and the values thus obtained for the earth-radiation effect extrapolated to zero thickness. In doing so account has to be taken of the effect of the screens upon q'_h.

Until more is known of the properties of the penetrating radiation, the relation of its ionising powers inside and outside a closed vessel cannot be stated with any certainty, but it is probable that unless the walls are very thick they will differ little from one another.

The greater part of the residual ionisation arises from α rays and takes place close to the walls ; q_0 is therefore the effect of the residual ionisation near the walls divided by the volume of the vessel.

§ 9. SUMMARY OF IONISING POWERS OF VARIOUS AGENCIES

The table on opposite page gives a rough idea of the effects of the three main factors in the ionisation of the air at sea-level, both in closed vessels of steel, a few millimetres thick, and in the free atmosphere. The values given refer to measurements at about a metre from the surface of the earth ; they are averages and, except in the case of the penetrating radiation, are subject to considerable fluctuations with local conditions.

It is noteworthy that the rate of production of ions over land areas is about six times as great as over the oceans, where the ionisation is practically all due to the action of the penetrating rays. Over land close to the surface of the earth, these rays are much less important, but at greater heights the effects of the earth and the air-radiations fall off rapidly as we have seen, so that here also, from a height of one of two kilometres upwards, the penetrating radiation is the chief agent in making the air a conductor.

§ 10. THE RATE OF DISAPPEARANCE OF THE SMALL IONS

The number of ions produced by the agencies we have discussed will not increase indefinitely as time goes on. Even in pure filtered air, free from nuclei, the small ions disappear by diffusion to the walls and by recombination with one another. Experiments have shown

TABLE I

IONISING POWERS AT THE EARTH'S SURFACE, SEA-LEVEL

Ionising Agent.	Ionising Power in Ion-pairs per c.c. per sec. in Air at N.T.P.			
	Unscreened Closed Vessel.		Free Air.	
	Over Land.	Over Sea.	Over Land.	Over Sea.
Radioactive matter in the earth . .	4·0	0	4·0	0
Radioactive matter in the air . . .	0·2	0	5·0	0
Penetrating Radiation	2·0	2·0	2·0	2·0
	Total ionising power for the free air .		11·0	2·0

that when the diffusion loss can be neglected, the equation $dn/dt = q - \alpha n^2$ applies to such filtered air, n being as before the number of positive or negative small ions per c.c., q the number of pairs of ions produced per c.c. per second, and α the so-called recombination constant of small ions. In the course of time a state of equilibrium will be reached, in which the processes of creation and disappearance of ions balance one another ; then $dn/dt = 0$ and the equilibrium equation $q = \alpha n^2$ holds. Applying this equation to the free air, taking $q = 11$ I from the preceding section and $\alpha = 1{\cdot}6 \times 10^{-6}$ cm.^{3}/sec. from laboratory experiments, we find $n = 2622$. This is very much larger than the number of small ions actually observed, which is round about 600 per c.c. The discrepancy is due to neglect of the important part played by the Aitken or condensation nuclei in capturing the small ions.

An equation applicable to air containing nuclei was first given by von Schweidler [6] in the form

$$dn/dt = q - \alpha n^2 - \gamma n Z,$$

where γ is a constant and Z the total number of nuclei, charged and uncharged, per c.c. of the air. For equilibrium, when dn/dt is zero, it becomes

$$q = \alpha n^2 + \gamma n Z = n(\alpha n + \gamma Z) = n(\alpha n + \beta) \qquad (6)$$

or

$$q = \beta' n \quad . \quad . \quad . \quad . \quad (7)$$

The quantity β' is known as the disappearance constant of the small ions. Experiment shows that in ordinary air, where nuclei are plentiful, the term αn is small compared with β ; even over the oceans it is probably only one-seventh of β. Thus β', while not a true constant, for it depends upon the concentration Z of the nuclei in the air, is to a large extent independent of the number of small ions per c.c. Equation (7) thus states a linear law of recombination as opposed to the quadratic law which holds for filtered air.

If the action of the ionising agents were removed, the small ions would disappear at a rate $dn/dt = \beta' n$, giving $n = n_0 e^{-\beta' t}$, for the number present at any subsequent time. It is assumed in the integration that there are sufficient nuclei present to make β' independent of n. Von Schweidler has pointed out that the quantity $\theta = 1/\beta'$ can, by analogy with the equation for radioactive decay, be termed the average life of a small ion. Equation (7) then becomes

$$q\theta = n \quad . \quad . \quad . \quad . \quad (8)$$

in which θ should vary inversely as the number of nuclei per c.c. of the air.

In a development of this theory put forward by J. J. Nolan and his co-workers, [2, 1] separate consideration is given to the capture of small ions by charged nuclei of opposite sign, leading to neutralisation, and by uncharged nuclei, leading to the formation of large ions. For the small positive ions, they write

$$dn_+/dt = q - \alpha n_+ n_- - \eta_1 n_+ N_0 - \eta_2 n_+ N_- = 0, \text{ for equilibrium} \quad . \quad (9)$$

Here N_0 and N_- are the numbers of uncharged and negatively charged nuclei per c.c. respectively, while η_1 and η_2 are the recombination coefficients for the two types of capture. By a theoretical discussion, too long to be reproduced, this equation is converted into the simpler form $q = [\eta_2 Z/2{\cdot}1]n$, which corresponds to Schweidler's equation (6) and again indicates that the average life of an ion should vary as $1/Z$.

This average life θ is found over land areas to lie between 10 and 60 seconds according to the purity of the air, the higher values being associated with observations made in the country. Over the oceans it may be as much as 230 seconds, according to the measurements of Hess [7] and of Mathias [8] on the island of Heligoland. The table below, taken from Hess, illustrates the great difference in the equilibrium between small and large ions brought about when the wind direction changes ; the first set of observations was made when the wind blew from the nuclei-laden European mainland, the second when it blew from the polar regions :—

TABLE II

OBSERVATIONS OF THE STATE OF ATMOSPHERIC IONISATION (HESS, HELIGOLAND)

Wind.	No of Small Ions per c.c (n).		No. of Large Ions per c.c.(N).		Total No. of Nuclei.	Average Life of Small Ion, secs.	
	n_+	n_-	N_+	N_-	$Z = N_0 + N_+ + N_-$	θ_+	θ_-
S.W. (Land)	220	267	1480	1510	6300	22	22
N.N.W. (Arctic)	794	843	200	200	1100	115	204

These authors find that for values of θ lying between 36 and 100 seconds, Schweidler's linear equation (8) is valid; in purer air, where θ is greater than 100 seconds, the simple equation no longer holds, for the quadratic recombination term αn^2 then becomes significant.

Experiments by P. and J. Nolan[9] and their co-workers have, however, suggested that the form of the accepted equilibrium equation is incorrect and should be replaced by a new empirical relation $q = n(\alpha n + \zeta\sqrt{Z})$, where ζ is a constant. For air with a sufficient concentration of nuclei this reduces to $q = [\zeta\sqrt{Z}]n$, which would imply that the mean life of an ion varies as $1/\sqrt{Z}$. It is therefore possible that the processes governing the disappearance of the small ions in the atmosphere are more complex than has hitherto been supposed. Account may have to be taken of variations in the actual nature of the nuclei, of complexities in the small and the large ion families, such as are indicated by the existence of "intermediate" ions, of the possible occurrence of multiply-charged large ions when the number of nuclei is small,[10] and of the effect of actual dust-nuclei.

§ 11. METHODS OF DETERMINING THE AVERAGE LIFE OF A SMALL ION

The average life, θ, of the small ions can be determined for a sample of air enclosed in an ionisation chamber by two methods suggested by Schweidler.[6] The first involves the separate measurement of the ionising power, q, of the ionising radiations, and of the number of small ions per c.c., n, and substitution in the equation $q\theta = n$. q is obtained from the saturation current, i, using the relation $i = qev$, where v is the volume of the vessel. The corrections to be applied have already been discussed (§ 8). The quantity n is found by allowing the air to stand undisturbed for a sufficient time for equilibrium between small ions and nuclei to be attained and then applying a strong field for a few seconds to sweep the small ions on to the collecing electrode. The second method involves the measurement of the currents flowing in an ionisation vessel for various values of the applied potential difference.[11]

§ 12. THE IONISATION-BALANCE IN THE LOWER ATMOSPHERE

It is of considerable importance to decide to what extent the various factors in the creation and destruction of ions account for the state of ionisation actually observed in the air over land and sea. Any failure in this respect would suggest that new processes must be sought.

The evidence available indicates, however, that the chief factors in the ionisation-balance have been discovered. Over land areas where nuclei are usually plentiful, the Schweidler equilibrium equation, $q\theta = n$, applies. An average value of 60 seconds for θ, the mean life of a small ion, and of 650 per c.c. for the small ion concentration, requires that the rate of creation, q, should be 650/60 or 10·8 ions/c.c./sec. in satisfactory agreement with direct measurements of q, shown in Table I. No direct measurements of θ have yet been made over the oceans. The concentration of nuclei in mid-ocean has been estimated by Hess, from measurements on air from the Arctic, to be such as to give an average life of 230 seconds to a small ion. Since n was found on the *Carnegie* to amount to about 550 small ions/c.c., the ionising power at sea should amount to 550/230 or 2·4 I. The agreement of this figure with the value 2·0 I shown in Table I. is reasonable, in view of the roughness of the estimate of θ used, and of the present uncertainty in the value of q itself.

Hess's estimate of the concentration of Aitken nuclei over the oceans, about 800 per c.c., is borne out by direct measurements on the *Carnegie*, which give means of 870 and 774 per c.c. in the Atlantic and Pacif measure-
respectively, and by a recent count eaks, or in balloons,
the Atlantic. oust and portable, as

The problem of the ionisation

cannot be said to be completely solved until agreement is reached on the form of the interaction-relation between small ions and nuclei. The general nature of the factors in the ionisation-balance has, however, been established, and an explanation can be given of the paradox that the conductivity of the air undergoes no large change as one passes from mid-ocean to land, despite a six-fold increase in the rate at which ions are formed. The increased birth-rate of the small ions is counterbalanced by an increased death-rate, owing to the greater concentration of predatory condensation-nuclei over the land areas.

CHAPTER II

THE PENETRATING RADIATION

UNTIL the year 1911 it was generally supposed that the ionisation inside a closed vessel was entirely due to radiations from the walls, and from radioactive matter in the earth and the outside air. It was therefore to be expected that this ionisation would decrease when the vessel was raised above the surface of the earth. This was tested in balloon ascents by Hess in 1911, and Kolhörster in 1913, who found that the diminution with height was only appreciable during the first kilometre, after which an increase occurred. These observations led Hess to postulate an ionising radiation coming from above and suffering partial absorption in the atmosphere.

Something has already been said of this radiation in § 7 ; the accurate determination of its properties has proved a difficult matter. Its great penetrating power implies that the ionisation it creates within a closed vessel is so small as to require specially refined technique to measure accurately in the presence of the other ionising agencies discussed in Chapter I. Further, the fact that it comes from above and suffers some absorption necessitates investigations at high altitudes so that any softer and more easily absorbed components which do not reach sea-level may be examined. Such measurements must be made on mountain peaks, or in balloons, under conditions which require robust and portable, as well as sensitive, instruments.

§ 13. Experimental Methods of Measuring the Intensity of the Radiation

The most extensive measurements of the intensity of the radiation have been made by the ionisation method. The first point to be attended to is to eliminate as far as possible the disturbing effects of the earth and air-radiations. This can best be done by sinking the ionisation chamber beneath the waters of a lake, or by surrounding it with a thick shield of non-radioactive iron or lead and correcting for the small fraction of the γ rays which are still able to enter the chamber.

The ionising power of the penetrating rays at sea-level is about 2·0 I (ions per c.c. per sec.), so that their contribution to the saturation current in a vessel of volume 1 litre, filled with air at N.T.P., would be $3{\cdot}2 \times 10^{-16}$ amperes. In order to increase this effect, it has become the general practice to fill the vessel with carbon dioxide at a pressure of 30 atmospheres or more.* This carries with it an important advantage, in that it considerably reduces the effect of the residual ionisation, which, we have already seen, is caused by α rays from the walls. The range of these rays in CO_2 at high pressure is small, and they produce all their effect within a few millimetres of the walls themselves. Here the electric field driving ions to the central collecting electrode is weakest and cannot separate out more than a small fraction of those produced before they recombine. A further decrease in the residual effect can be obtained by using a wire cage as an electrostatic screen to form the walls of an inner ionisation chamber. This cuts down the amount of wall material productive of undesirable α rays (Hoffmann, Fig. 4).

The quantity actually measured in these experiments is the sum of the penetrating ray and the residual ionisations, q_h and q_0, and fluctuations in the latter limit the accuracy with which q_h can be found. These arise from the fact that in a given time-interval the number of α particles emitted from the walls undergoes variations about a mean value which are subject to well-known statistical laws. To smooth them out it is generally necessary to make observations over a period of several hours. For accurate measurements in a shorter time instruments have been devised by Hoffmann[1] and by the author[2] which are sensitive enough to show the sudden increases in the ionisation due to single α particles and so to determine the residual ionisation directly.

---

* Increasing the pressure does not give a proportional increase in ionisation. For 30 atmospheres the effect is only 14 times that at N.T.P. and the actual factor is somewhat uncertain. Hence the difficulty of finding the absolute value of q_h.

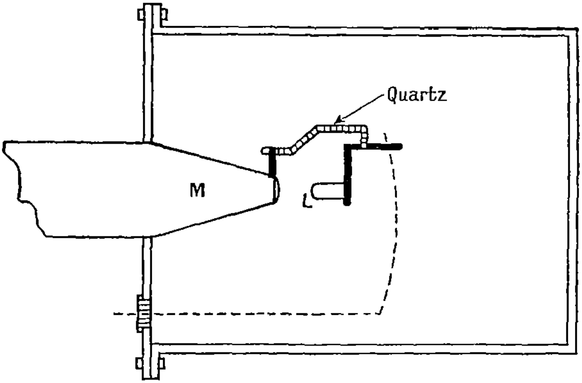

FIG. 3.—Kolhörster ionisation chamber and electroscope.

The portable instrument developed by Kolhörster is shown diagrammatically in Fig. 3. The ionisation chamber is of steel, coated inside with zinc, and is filled with purified air at atmospheric pressure. Two small loops L of platinised quartz fibre, mounted upon a rod held in a quartz insulator, form the central electrode and can be charged by a device operated from outside by an electromagnet (shown dotted). Their potential is determined from their distance apart as read in the eye-piece of a microscope M. In Millikan's instrument quartz fibres are also used as the central electrode, but the gas-filling is CO_2 at a pressure of 30 atmospheres. In both cases the quartz and invar-steel framework supporting the fibres is designed to reduce the effects of temperature variations. The chief disadvantage of this type of chamber is the small volume permissible in view of the pressure and the use of a high-power microscope. The penetrating radiation ionises the gas through the agency of fast-moving particles (§ 17) which fluctuate in number like the α particles from the walls. To smooth them out in the case of small ionisation vessels necessitates observations extending over many hours.

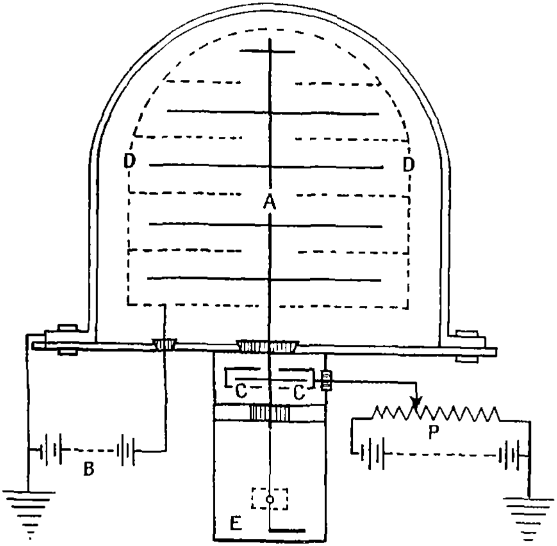

FIG. 4.—Hoffmann's null method for the measurement of the ionisation due to the penetrating radiation.

Another type of apparatus, due to Hoffmann,[3] employs an electrometer which is outside the ionisation vessel (Fig. 4). The chamber is filled with CO_2 at a pressure of about 30 atmospheres, the residual radiation is reduced by the use of a wire cage for the walls of the ionisation vessel proper, and saturation conditions are obtained by adopting the branched form of central electrode A and cage D. The electrometer E is of a specially sensitive type developed from the quadrant electrometer. It serves as a null instrument, for arrangements are provided to maintain the whole central system at zero potential. The cage is kept permanently charged by means of the battery B, and the charge carried to the central electrode by the ions is compensated for by an equal and opposite charge induced upon the inner plates of the small condenser C by means of the potentiometer P. The amount of charge collected during a given time can be found from the capacity of C and the potential applied to the outer plates. Both C and the electrometer are kept evacuated. Though more complicated and less portable than the first type, this instrument has the advantages of freedom from all insulation losses on the collecting system and of greater volume.

The more recent portable instruments show a reduction in the ionising power of the residual wall radiation; in Millikan's 1926 form the ratio of this quantity to the ionising power of the penetrating radiation at sea-level was 4·5/1; in the form used by him in 1930 this had been reduced to 1/30. The ratio for Hoffmann's instrument is less than 1/5.

§ 14. The Ionisation-depth Curve in Air and Water

In studying the variation of the ionisation intensity of the radiation above and below sea-level, it has been found convenient to measure distance downwards from the top of the atmosphere. This distance is usually expressed in equivalent metres of water, i.e. in terms of that column of water which would possess the same mass per unit area of cross-section as the column of air above the point of observation. Thus sea-level is 10·33 equivalent metres of water below the top of the atmosphere.

Observations of the ionisation at various depths below the top of the atmosphere are most conveniently made by sinking an ionisation vessel in a lake situated at a very great altitude. The results when plotted against the total depth, equivalent and real, of water below the top of the atmosphere constitute an ionisation-depth curve. An extensive series of investigations has been carried out by Millikan and Cameron to determine the shape of this curve, using lakes on mountain peaks in both North and South America.[4] Thus they were able to examine the absorption of the rays from near the surface of Gem Lake, California, where the depth below the top of the atmosphere was 7·4 equivalent metres of water (altitude 3000 metres), down to 81 actual metres below the surface of the lake, 86 equivalent metres from the top of the atmosphere. Owing to the need for some water-screening to cut down the air-radiation effect, q'_a, trustworthy observations began at a total depth of some 8 metres.

They have repeated these observations in other lakes at lower altitudes and have been able to show that at the same total depth below the top of the atmosphere the ionisation is always the same. This indicates that within the reasonably high accuracy of their measurements, the absorbing power of the additional thickness of air involved in the observations at lower altitudes is in fact that of the equivalent layer of water. As a consequence of this result measurements made at still greater altitudes on mountain peaks and in balloons can be plotted on the ionisation-depth curve for water with some degree of confidence that the absorption in the air can be reduced to that in water in this way. Observations made in air alone, however, require the instrument to be shielded with lead from the external earth and air-radiations and have not only to be corrected for the small fraction of these which can still penetrate the shields but also for the absorption of the penetrating radiation in the lead. For these reasons they are not so reliable for plotting on the curve as the measurements made in water.

The ionisation-depth curves obtained by Millikan and Cameron are shown in Fig. 5, the portion below 30 metres being inset on a larger scale. The observations made in Lake Arrowhead (altitude 1700 metres) and Gem Lake (altitude 3000 metres) constitute the main "water" curve. The curve marked "land" shows the land observations made at various heights from sea-level to the top of Pike's Peak, California (altitude 4700 metres, 6·2 equivalent metres of water below the top of the atmosphere), inside a thick lead shield. By comparing the abscissæ of the land and water curves for the same ordinate, the water-equivalent of the shield at the higher altitudes was found to be 1·22 metres. The dotted portion of the water curve is obtained by adding this amount to the equivalent depth of the land observations.

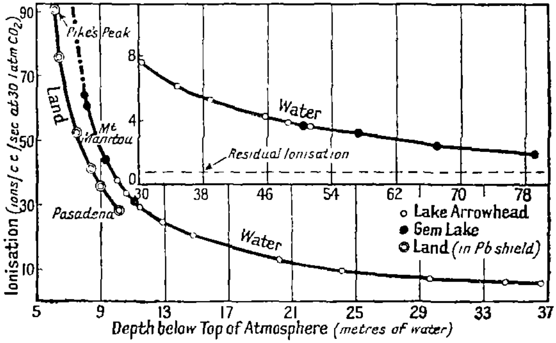

FIG. 5.—Ionisation-depth curve in air and water (Millikan and Cameron).

Even at a total depth of 80 metres the water curve is not parallel to the horizontal axis and the value of the residual ionisation (1·2 ions/c.c./sec. in CO_2 at 30 atmospheres) has to be obtained by extrapolation.

These measurements show clearly the very great penetrating power of the radiation, for the most penetrating known gamma rays (from thorium C″) would be reduced to one-fiftieth of their original intensity in their passage through a single metre of water. The lower part of the ionisation-depth curve has been extended still further by Regener [5] in experiments on Lake Constance. His ionisation vessel had a volume of 34 litres and was filled with CO_2 at a pressure of 30 atmospheres. This was surrounded by a protecting tank filled with water from the surface of the lake which formed a screen

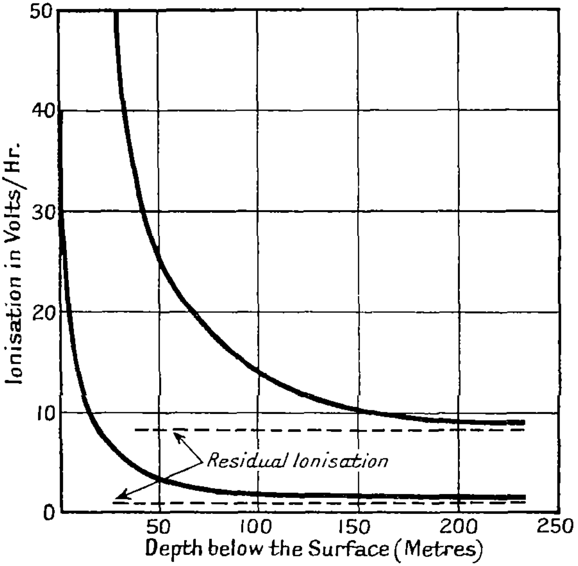

Fig. 6.—Ionisation-depth curve (Regener).

1 metre in thickness and prevented possible variations with depth in the small radioactive content of the surrounding water from affecting the measurements. With this arrangement Regener has followed the radiation down to a depth of 230 metres of water below sea-level, the large volume of the chamber enabling accurate measurements to be made even at great depths. At 230 metres the curve was found to be still falling and could still be determined with an error of the order of 2 per cent. The movement of the fibres of the electrometer was recorded automatically by photographing their position at intervals of one hour. Regener's curve is shown in Fig. 6, with the ordinates of the portion below 30 metres repeated on a tenfold scale.

§ 15. ANALYSIS OF THE IONISATION-DEPTH CURVE

The form of the ionisation-depth curve suggests that it may be made up of three or four separate curves corresponding to component radiations of different penetrating powers. On this view the initial steep portion would correspond in the main to an easily absorbed component which does not reach sea-level in any quantity compared to the others, while only the most penetrating component can reach to the great depths examined by Millikan and Regener. In endeavouring to analyse the curve in this way it has been assumed that the process of absorption of a parallel beam of the s-th component is represented by the well-known equation $-dI = \mu_s I dH$, where $-dI$ is the decrease in the ionisation I due to passage through a thickness dH of the absorbing medium and μ_s is a constant, characteristic of the radiation and of the medium, which is called the absorption coefficient of the s-th component. Integration of this equation gives $I = I_0 e^{-\mu_s H}$. The significance to be attached to μ_s will be discussed later.

There is, however, no reason to believe that the radiation strikes the top of the atmosphere as a parallel beam, and we must assume incidence with equal intensity in all directions and take account of the increased thickness of air or water to be traversed as the angle of incidence is increased. When this is done, it is found that the relation between the ionisation I at a depth H and that which would be found at the top of the atmosphere, I_0, takes the form $I = I_0\int_1^\infty [e^{-\mu_s H x} \,.\, dx/x^2]$.* Tables of this integral have been given by Gold.

The analysis of the ionisation-depth curve must be carried out by a trial and error method, for not only the number of components but the absorption coefficient μ_s and the initial intensity I_0 of each has to be chosen to fit the curve. Analyses of this kind have been made by Millikan and Cameron, and by Regener, whose results are shown in the following table :—

TABLE III

ANALYSES OF THE IONISATION-DEPTH CURVE INTO COMPONENTS

Compt.	Millikan.		Regener.	
	Absorption Coefficient, μ_s.	Intensity at Top of Atmosphere, I_0.	Absorption Coefficient, μ_s.	Intensity at Top of Atmosphere, I_0.
1	0·80 *metres*$^{-1}$	141,000	?	?
2	0·20 ,,	130	0·21	130
3	0·10 ,,	80	0·073	51
4	0·03 ,,	33	0·02	6·5

The values of μ have been expressed in reciprocal metres of water ; in the same units the mean absorption coefficient of the gamma rays from radium B + C after filtration through 10 mm. of lead would be 5·4. Since Regener's experiments did not extend above sea-level he has not been able to determine the constants of the most easily absorbed component.

---

* See Rutherford, *Radioactive Substances and their Radiations*, p. 262, where x = sec θ.

The agreement obtained by these independent observers for the other three components is striking; slight discrepancies in μ may be explained by the uncertainty in the exact value of the residual ionisation, for the curves are still falling at the lowest depths reached. The difference in relative intensities may be due to some selective action arising from the difference in the size of the chambers used.

§ 16. IONISATION-DEPTH CURVES IN HEAVY METALS: THE TRANSITION ZONE

The absorption of the radiation in heavy metals has been studied by placing metal screens round the ionisation vessel. Since this corresponds to sinking it in a lake of the metal, the results obtained should agree with the ionisation-depth curve taken in water when the thickness of each screen is expressed in equivalent metres of water. It is, however, found that the absorbing power of a metal such as lead is initially very high. The curve falls abnormally rapidly at first (for 10 cm. in the case of Pb); afterwards it runs parallel to, but lower than, the water curve, additional screens producing the same reduction as their water-equivalents.* It has been shown that this effect is due to the transition from air to lead, and something similar is exhibited in all transitions from one medium to another. Fig. 7, after Steinke,[6] shows the ionisation-depth curves of aluminium and lead as thick lines. The effects of adding an inside layer of Pb after 28 cm. of Al have been used, and of adding inside layers of Al after 4 and 10 cm. of Pb, are shown by the dotted lines. The increase in the ionisation in two of these cases is very remarkable. It is suggested that the transition zone effect is due to an alteration in the equilibrium between the primary rays and their secondary electrons (§ 20), but no quantitative explanation can yet be given. The phenomenon is of great importance in connection with the problem of the nature of the radiation.

---

* In this work the water-equivalent is that thickness of water with the same number of extra-nuclear electrons in a column one sq. cm. in cross-section. Millikan's water-equivalents (§ 14) are mass-equivalents.

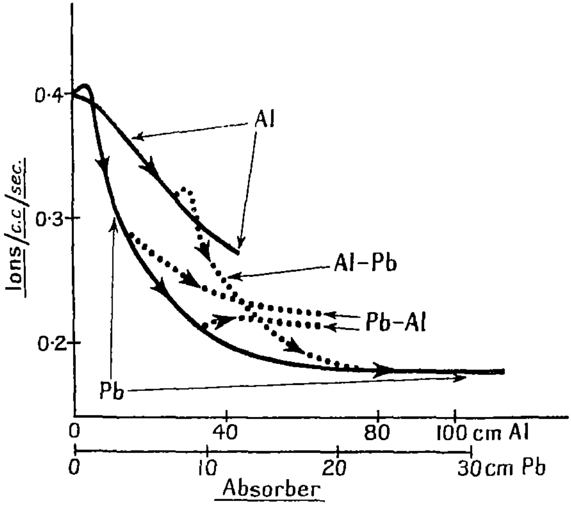

Fig. 7.—Transition-zone effects in Pb and Al (Steinke).

A striking instance of the initial drop in the absorption curve in lead is afforded by a screen used by Millikan in mountain observations. Its calculated water-equivalent was 85 cm., but a comparison with the ionisation-depth curve in water showed that it was effectively 170 cm. at sea-level and 122 cm. at a height of 5000 metres.

§ 17. PHOTOGRAPHIC REGISTRATION AND COUNTING OF THE IONISING PARTICLES

The ions produced by the rays can be studied by means of the Wilson cloud chamber, in which a water-drop is condensed on each. Skobelzyn [7] has shown in this way that much of the ionisation is due to the action of fast-moving particles which travel in a downward direction at the rate of about one particle per square centimetre per minute at sea-level. The photographs of their tracks show that they create some 40 ion-pairs per centimetre of their path in ordinary air.

It is not yet certain whether all the ionisation arises from particles of this kind. A number of the tracks show a paired relation which may be significant, two or more particles entering the chamber during one expansion in directions making a small angle with one another.

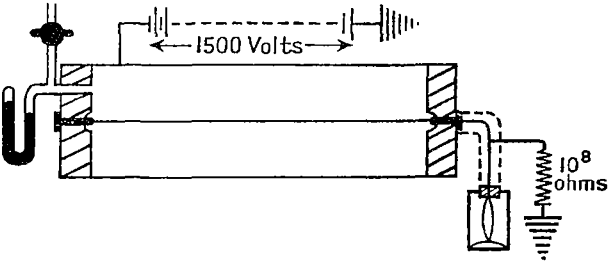

FIG. 8.—Geiger-Müller tube-counter.

The passage of these ionising particles can be continuously recorded with the tube-counter of Geiger and Müller. In this (Fig. 8) the ionisation vessel is a tube of zinc and the collecting electrode a thin wire along the axis, coated with a semi-insulating layer of oxide or varnish. Conditions of pressure and potential difference are adjusted below the sparking value so that the entry of each ionising particle gives rise to a sudden pulse of current of very short duration. The advantage of this device is that the effect of an α particle is equal to that of a β particle, instead of 200 times greater as in the ordinary ionisation chamber. The same cleaning and screening precautions as have been described for the latter must be taken. This counter has been used by Regener [5] to confirm the readings on his ionisation-depth curve; the submerged counter was joined to an arrangement which recorded each pulse automatically.

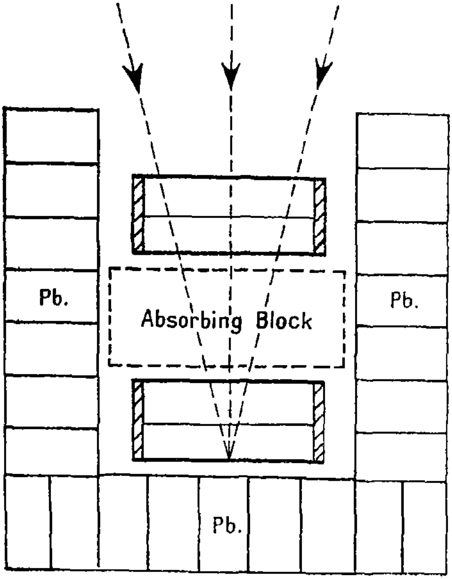

Fig. 9.—The Bothe-Kolhörster experiment.

An apparatus which counts the penetrating ray particles only has been developed by Kolhörster and Bothe (Fig. 9). Two counters are mounted vertically above one another, and account is taken only of those pulses which coincide in time with one another and are considered to be due to the passage of particles which are able to penetrate both counters. The coincidences were originally determined by recording the sudden deflections of both electroscopes on the same moving photographic film. In a development due to Bothe,[8] the two counters are joined to the two grids of a screened-grid valve which is so arranged that a pulse of plate current occurs only when both grids are practically simultaneously changed in potential.

§ 18. The Bothe-Kolhörster Experiment

Bothe and Kolhörster[9] have used this arrangement to determine the absorption coefficient of the ionising particles themselves. A block of gold 4·1 cm. thick was placed between the counters, and the reduction in the number of coincidences was observed. The value found for the absorption coefficient was so close to that given by the usual ionisation chamber method as to lead them to conclude provisionally that the ionising particles are the primary radiation and not of secondary origin. In an extension of this experiment carried out by Rossi,[10] however, evidence was found of the actual production of fresh ionising particles when the radiation was absorbed. These presumably arise from a primary radiation of γ ray type.

§ 19. The Energy of the Ionising Particles

If the ionising particles are electrically charged, the deformation of their paths in a transverse magnetic field should give information as to their nature and energy. Several unsuccessful experiments of this kind have been interpreted as indicating that their momentum is too great for them to be bent in the fields used. Mott-Smith[11] in this way has placed a lower limit of 2×10^9 *e*-volts * to their energy if they are electrons, and 10^9 *e*-volts if they are protons.

The Bothe-Kolhörster-Rossi experiment suggests that the effective range of the particles is about 10 equivalent metres of water or $7{\cdot}7 \times 10^5$ cm. of air at N.T.P. They produce some 40 ion-pairs per centimetre of air and each ion-pair costs the particle about 30 *e*-volts. Hence the total initial energy of a particle must be of the order of $40 \times 30 \times 7{\cdot}7 \times 10^5$ or $9{\cdot}2 \times 10^8$ *e*-volts.

In experiments carried out under thunderstorms,[2] the author has found that the strong electric fields within and outside the cloud are able to stop a large proportion of these particles. He concludes that their energy must be less than 5×10^9 *e*-volts, if they are electrons or protons.

Such energies are more than a hundred times greater than those of the fastest particles emitted by radioactive bodies. If the particles are electrons they must be moving with a velocity only about 40 metres per second less than that of light and their inertial mass is 2000 times their rest-mass, slightly greater than the mass of a slow proton. At such energies electrons and protons may be expected to give approximately the same ionisation per unit path and the same absorption coefficient.

It has recently proved possible to obtain magnetic bending of the tracks in a Wilson cloud-chamber.[18] The paired particles are found to be of two types, positively and negatively charged, presumably protons and electrons. Their energies range from 10^7 to 10^9 *e*-volts.

§ 20. The Nature of the Penetrating Radiation

In view of the difficulties in the way of determining the nature of the fast ionising particles and of some uncertainty as to whether there are not other ionising rays of much shorter range, any discussion of the nature of the penetrating radiation itself is purely tentative. In this section two of the many important points which have been raised in this connection will be outlined.

---

* Electron-volts, the energy expressed in terms of the difference of potential in volts through which an electron must travel to attain this energy.

The first concerns the effects to be expected if the primary radiation is itself constituted of fast-moving charged particles. In such a case the earth's magnetic field should produce a deflection of their paths leading to a concentration of the particles in the higher magnetic latitudes. Brucke has shown that for a fast electron to reach the earth's surface below magnetic latitude 50° its energy must exceed 5×10^9 volts, and for it to attain the equator it must have twice this energy, even if loss of energy in passage through the air be neglected. This question is being investigated at the present time; Millikan[12] has shown that the sea-level intensities in latitudes 59° and 34° are the same within the limits of accuracy of his measurements (1 per cent.). These and other observations speak against a corpuscular nature for the primary rays.

The second point concerns the view that the ionising particles are secondary electrons arising from the passage of primary ultra-gamma ray quanta through the atmosphere, and the utilisation of absorption coefficients derived from the ionisation-depth curve to find the frequencies of these quanta.[13] On this view an ionising particle is produced when a quantum of energy $h\nu$ makes a Compton collision with an electron in an atom. The electron moves forward with energy $h(\nu - \nu_1)$ and the quantum recoils with a lower "degraded" frequency ν_1. Consideration of the equations governing the Compton scattering process shows that for high-frequency quanta the collision in most cases leaves quantum and electron moving forward along paths only slightly inclined to one another, so that the radiation at any point within the atmosphere should consist of a mixture of primary and degraded quanta of various orders (the results of one, two, and more successive collisions) together with the fast electrons arising from collisions of primary and degraded quanta.

Absorption measurements are made upon this mixed beam and yield an absorption coefficient $\bar{\mu}$; what relation this bears to the absorption coefficient of the pure primary radiation, μ, can be determined only by involved calculation. Since the degraded quanta have frequencies ν_1, ν_2, etc., which are less than the primary frequency ν, they are more easily absorbed than the primary quanta. Thus, as the radiation travels through the air, there will come a stage when as many degraded quanta of each kind disappear in each centimetre of path as are produced by Compton processes in the same centimetre. The parent beam is then in equilibrium with its *quantum* products in the same way as a long-lived parent radioactive body such as radium reaches equilibrium with its descendants. From this stage onwards, say after a thickness equivalent to D cm. of water, the constitution of the quantum part of the beam will remain unaltered, and this part will disappear at a rate set by the rate of disappearance of the primary quanta. Until this stage is reached $\bar{\mu}$ cannot equal μ.

Actual absorption measurements, however, are concerned with the ionising electrons and not with the quanta which give rise to them. Consider the first scattering process only, which we may assume for simplicity to give rise to electrons all of the same range, R cm. of water. Then the ionisation at a depth H cm. of water below the top of the atmosphere will be due to electrons from points lying between H and H − R cm. from the top. Thus the actual measurements reflect the state of the beam some distance above the point of observation and can give only an apparent absorption coefficient $\bar{\mu}$ which equals μ, provided that $H - R > D$. If this condition is not fulfilled, the number of electrons brought to rest in 1 cm. is less than the number generated in the same distance and $\bar{\mu}$ will be less than μ.

The ionisation-depth curve has been analysed into four component curves, distinguished by different values of $\bar{\mu}$. The significance of these apparent absorption coefficients obviously depends upon how far the criteria for equilibrium are satisfied in each case. Since according to Millikan, only the least penetrating component reaches equilibrium with its electrons and degraded quanta, the values of $\bar{\mu}$ found for the others will be less than μ. The deduction of their true absorption coefficients is at present impossible, for it involves a wide extrapolation of the laws governing the passage of γ and β rays through matter. Recent experiments have shown that these processes are not completely accounted for by existing theories. In particular, high-frequency quanta interact with atomic nuclei in a manner which is likely to be very important in the case of the penetrating radiation. The paired proton and electron tracks referred to in §§ 17 and 20 show that the rays frequently disintegrate atomic nuclei. This process is not taken into account in the γ ray absorption formulæ. If the radiation does consist of a mixed beam of ultra-gamma quanta and fast electrons, the observed absorption coefficients do not in general approximate to the true coefficients, and it is not possible to deduce the quantum frequencies except perhaps in the case of the softest component.

§ 21. The Origin of the Radiation

The intensity of the radiation is remarkably constant, and no certain variation with solar or sidereal time has been established. Corlin[14] and others have put forward evidence of a sidereal time effect which decreases with depth below the top of the atmosphere and amounts at sea-level to about 2 per cent. of the mean intensity. The effect only shows in averages of a long series of hourly observations, for alterations in the effective thickness of the atmosphere (not always faithfully represented by changes in the barometer) and other causes give rise to larger and irregular fluctuations.

Hoffmann, with the sensitive instrument described in § 13, can find no evidence for a sidereal time variation. A suggested solar effect also awaits confirmation; if it exists at all it is very small ($\frac{1}{3}$ per cent).[16]

It is most natural to look for the source of quanta of such high energy in the interiors of the hot stars, where high temperatures may lead to the conversion of matter into radiation. This possibility has, however, been rejected owing to the absence of appreciable solar and sidereal time effects.

Another argument against it is provided by the estimated total energy reaching the outer atmosphere in the form of penetrating radiation. This is more than one-tenth, probably one-fifth, of the total energy arriving from all the stars as light and heat. If the radiation originated in stellar interiors, very little of it could escape unaltered and most of it would be turned into heat. Unless, therefore, the radiation is generated only in the outermost layers of the stars, it is not possible for it to convey anything like such a large fraction of the total stellar radiation as one-fifth.

Millikan [4] has considered the possibility of the radiation arising from the formation of more complex elements out of hydrogen in interstellar space. The mass of a heavy atom being less, by Δm, than the separate masses of its constituent protons and electrons, energy of amount $\Delta m \times c^2$ ergs would be radiated out as a quantum whose frequency is given by $h\nu = \Delta m \times c^2$, where c is the velocity of light. He considers that the four main components of the radiation (§ 15) represent the formation of the four most abundant groups of elements, apart from hydrogen, viz. helium, "oxygen" (C, N, and O), "silicon" (Mg, Al, and Si), and "iron" (Fe, Ni, and Co). These elements make up 99 per cent. of all known matter, excluding hydrogen. The atomic weight determinations of Aston with the positive ray mass spectrograph give Δm in each case, and thus the quantum frequencies, ν, can be calculated. The corresponding absorption coefficients, μ, are calculated by extrapolating the relation which holds approximately in the gamma-ray region. The theoretical coefficients for the four groups are ·796, ·241, ·142, and ·075 m^{-1} H_2O, respectively, and are to be compared with the four values of the apparent absorption coefficients, $\bar{\mu}$, from the ionisation-depth curve (Table III), ·80, ·20, ·10, and ·03. Millikan attributes the disagreement in the last three cases to a failure on the part of the more penetrating components to reach equilibrium with their secondary electrons. This, as we have seen (§ 20), would cause $\bar{\mu}$ to be less than μ, but the difficulty of making a quantitative check on this point and the impracticability of any extrapolation of the $\nu - \mu$ relation have delayed acceptance of the theory.

C. T. R. Wilson[15] has suggested that part at least of the radiation may be of terrestrial origin and come from thunderclouds. A β particle of radioactive origin emitted upwards in the strong field within the electrified cloud would, he has shown, rapidly increase in energy, for the gain of energy from the electric field would exceed the loss of energy by ionisation along its path. Since he and others consider the electric field within the cloud to be in general directed downwards, a thundercloud should spray upwards a stream of " runaway " electrons of energy up to 5×10^9 *e*-volts (see § 42). These would either be bent down in the earth's magnetic field to strike the earth at distant points or would be converted by direct hits with atomic nuclei into ultra-gamma quanta. Attempts to find direct evidence of this effect are at present being made.

A suggestion that the dissolution of matter into radiation may be responsible for the more penetrating components of the rays has recently been supported by the argument that the smallest absorption coefficient found by Regener (·0205 m^{-1} H_2O) corresponds on certain reasonable assumptions (Jeans[17]) to the value calculated for the radiation arising from the complete dissolution of a particle within the nucleus of a heavy atom (·020 m^{-1})

Some workers consider that apparent contradictions in the results of experiments on the radiation arise from the fact that it consists of fast-moving "neutrons," proton-electron combinations endowed with no resultant charge but having a magnetic moment.

CHAPTER III

ELECTRIC FIELDS AND ELECTRIC CURRENTS IN THE ATMOSPHERE

§ 22. THE FINE-WEATHER FIELD

IT was first found in the year 1752 by Lemonnier that the air above the earth is the seat of a persistent electric field during fine weather. The direction of this field shows that the earth carries a negative charge and the upper layers of the air a positive one. The state of affairs close to a flat portion of the surface of the earth can be expressed in three ways: (*a*) the earth carries a charge of surface density σ per unit area; (*b*) there is a vertical field of strength $F = 4\pi\sigma$, just above the ground; or (*c*) between two horizontal planes close to the ground there is a difference of potential

$$dV = V_{h+dh} - V_h = - Fdh = - 4\pi\sigma dh,$$

where $h + dh$ and h are the heights of the planes.

The quantity dV/dh is called the potential gradient and is positive, since σ is found to be negative. For the same reason, the field F is directed downwards, and this downward direction is by convention adopted as the positive direction for electric fields in the atmosphere. In these definitions it is assumed that the portion of the ground considered is flat and far removed from projections, such as trees and buildings, which would disturb the distribution of charge and concentrate the lines of force at certain points.

The average value of the fine-weather potential gradient is about 100 volts per metre; the corresponding value for the average charge density is $2{\cdot}7 \times 10^{-4}$ electrostatic units per square centimetre or ·0009 coulomb per square kilometre. The total fine-weather charge on the earth is of the order of 500,000 coulombs. Measurements of the fine-weather field are made by determining either σ or dV/dh; they are always expressed in terms of the latter, in volts per metre.

§ 23. DIRECT MEASUREMENT OF THE SURFACE DENSITY OF THE EARTH'S CHARGE

The charge on such a limited portion of the ground as can be isolated for the determination of σ is so small that a sensitive electrometer must be used to measure it. Fig. 10 illustrates the "Universal portable electrometer" devised by C. T. R. Wilson for this purpose. A flat circular plate P, called the test-plate, is surrounded by a guard-ring and mounted flush with the surface of the earth but insulated from it. This plate is joined to a gold-leaf electroscope G, whose leaf moves inside a positively charged case and is observed through a telemicroscope. C is a variable cylindrical condenser, called a compensator, with its inner plate joined to the gold-leaf system, and its outer plate maintained at a constant potential, $-$ V.

To make a measurement, the instrument is initially shielded from the earth's field by placing over it the earthed metal cover Q, indicated by the dotted lines. The reading of the leaf corresponding to earth or zero potential is found by momentarily earthing the plate P and the gold-leaf system with the key K. This earthing key is then withdrawn, the cover removed and the plate exposed to the field, with the compensator capacity zero. A negative charge thus appears by induction upon P, an equal positive charge is set free upon the central system, and the leaf moves inwards. It can be restored to its zero position if a negative charge is induced on the central system by increasing the capacity of the compensator to a value C′. The charge on the test-plate is then − C′V and the surface density, σ, is − C′V/A, where A is the area of the test-plate.

In its original form the apparatus is small and portable,

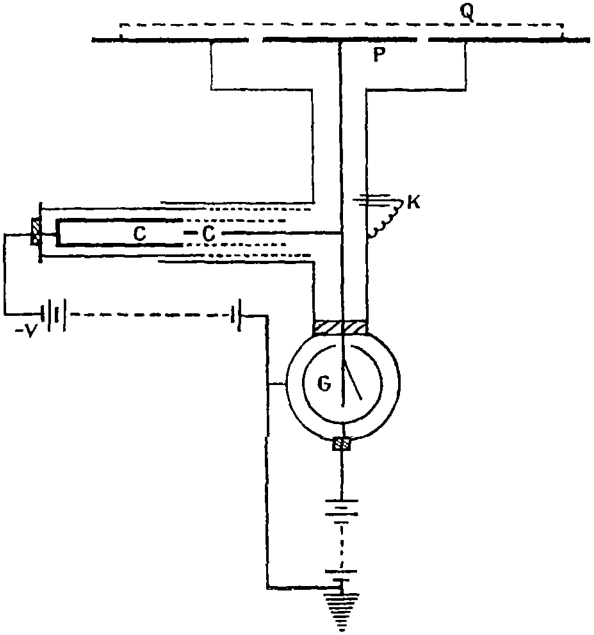

Fig. 10.—Universal portable electrometer (Wilson).

and the two batteries shown in the figure are replaced by small Leyden jars of silvered quartz, which keep their charge for a considerable time. For absolute measurements, with the plate mounted at ground level, a pit must be provided to house the observer ; very often relative measurements are made with the instrument mounted on a tripod, and the factor necessary to reduce the observations to standard conditions determined from simultaneous observations in a pit or with a potential gradient method. Since the lines of force are concentrated upon any projection above the earth, the factor is greater than unity; in the case of a tripod 1 metre high it amounts to 3 or 4. A useful method of calibrating the instrument is to place it in artificial electric fields of known strength. Two large flat metal sheets, one flush with, and the other above, the test-plate, are charged to a measured difference of potential by means of a battery of small cells.[1]

§ 24. MEASUREMENT OF THE POTENTIAL GRADIENT

The potential gradient dV/dh may be found by measuring the difference of potential between two insulated conductors at different heights above the ground. Various forms of electrometer are employed, and one conductor may be the earth itself, while the other is a stretched horizontal wire about a metre above ground-level. Sometimes two wires at different heights are used. It is of course essential that the supports of the wires and the presence of the observer and his instruments should not materially alter the field to be measured. In the arrangement in Fig. 11 (*a*), the wire

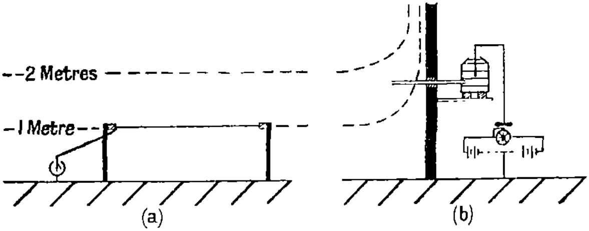

FIG. 11.—Measurement of the potential gradient.
(*a*) Absolute determination in open field.
(*b*) Continuous recording with the Kelvin water-dropper.

is hung between amber or sulphur insulators at the ends of two vertical rods; its length should exceed twice its height above ground.

The wire when first set up is at a different potential to that of the air in its neighbourhood, and a current will flow between them which tends to remove this potential difference. The ordinary conductivity of the air is, however, too small for this process of equalisation to take place very rapidly and the electrometer reading will always lag behind a fluctuating field. It is necessary for this reason to place at the centre of the wire some active ionising agent which speeds up the process by increasing the local conductivity of the air. This may take the form of a glowing fuse of filter-paper, impregnated with a 5 per cent. solution of lead nitrate, or of a disc or spiral of metal coated with a deposit of ionium or radio-thorium. Such "collectors," as they are called, have the advantage of causing the wire and the electrometer to acquire the potential of the air at the centre of the stretched length, where the electric field is least disturbed by supports and observer. The time taken for equalisation of potential depends upon the type and activity of the collector and varies from 1 to 60 seconds. There is always some uncertainty as to the exact position at which the ionising agent exerts its effect, especially if a wind is blowing, but this can be avoided by making observations at different heights.

§ 25. CONTINUOUS RECORDING OF THE POTENTIAL GRADIENT

An adaptation of the arrangement just described is employed to obtain continuous records of the potential gradient, the electrometer being housed in a building and the collector carried on an insulated rod projecting from the wall. The earth's field is very much distorted by the presence of the building, and a reduction factor for the installation must occasionally be determined by making simultaneous measurements in an open field. Fig. 11 (*b*) shows the nature of the distortion of the equipotential surfaces due to a building.

The Kelvin water-dropper is still largely used at recording stations as a potential equaliser. A jet of water from an insulated cistern within the building escapes from the end of a pipe passing through and insulated from the wall, and breaks up into fine drops at the point where the potential is required (Fig. 11). On starting the jet, the potential of the insulated system will in general be somewhat lower than that of the air at the end of the pipe ; this end will carry an induced negative charge and the cistern a positive one. Each drop carries a negative charge away and leaves the system slightly higher in potential than before. Ultimately the negative charge at the end of the pipe disappears and the system is at the potential of the air at the point at which the drops break away. In practice this takes a time of the order of 30 seconds.

Radioactive collectors are also employed, but whatever the type of collector, the insulated system is usually joined to the needle of a quadrant electrometer of low sensitivity, and opposite pairs of quadrants connected to a battery whose centre is earthed. The record can be made intermittently, by means of a clockwork arrangement which depresses an inked pointer attached to the needle (Benndorf), or continuously, by receiving the spot of light from a small mirror on a moving strip of bromide paper.

§ 26. VARIATION OF THE POTENTIAL GRADIENT WITH HEIGHT ABOVE THE GROUND : SPACE-CHARGE

A good many observations of the potential gradient have been made with balloons fitted with collectors of the radioactive or the glowing fuse pattern ; they all indicate a rapid decrease in the field with increasing height above the ground (Table V, § 33). Though no great accuracy can be claimed for these measurements —for they are subject to errors arising from the distortion of the field by free and induced charges on the balloon and are but momentary observations of a quantity subject to considerable variation—it is well established that at a height of 10 kilometres the field has fallen to less than 1/50 of its value at ground level and is diminishing still further. Some recent experiments of Idrac,[2] in which a thermionic valve was employed as a voltmeter, suggest that at very great heights the gradient may sometimes be reversed in direction, but the significance of these results is not yet clear.

This rapid diminution in the potential gradient with height indicates that a free positive charge, practically equal to the negative charge on the surface of the earth, resides within the lower 10 or 15 kilometres of the atmosphere. Integration of the values of dV/dh obtained in balloon ascents gives a total potential difference between the earth and the air at a height of 15 kilometres of about 3×10^5 volts; at this height, and above it, the conductivity of the air is so great that this figure may be taken to represent the potential of the highly conducting "Kennelly-Heaviside layer" some 80 kilometres above the ground.

The density, ρ, of the positive "space-charge" referred to can be determined from Poisson's equation, which, if the lines of force are vertical, takes the form $\frac{d}{dh}(dV/dh) = -4\pi\rho$. Several investigators have endeavoured to examine the nature of the space-charge quite close to the ground, using collectors at different heights. The results obtained are conflicting as to the magnitude, and even the sign, of ρ in this region; evidently local conditions are of main importance.

§ 27. VARIATIONS OF THE POTENTIAL GRADIENT WITH LOCALITY, TIME AND SEASON

Before passing on to the more important variations of the potential gradient, mention should be made of the fact that incessant fluctuations are observed over short periods of time; these are due to local changes in the space-charge and the conductivity of the air in the vicinity of the collector.

For many years continuous records of the potential gradient have been taken at certain stations in the Northern Hemisphere. Less extensive information is available for the Southern Hemisphere, but observations have been made over considerable periods in the Arctic and Antarctic regions. Some very important measurements over the oceans have been carried out by the survey ship *Carnegie* of the Carnegie Institute of Washington. It appears that the sign of the potential gradient in fine weather is positive all over the earth's surface, but that over land areas its value varies considerably with local conditions. The mean of dV/dh at Kew is 317 volts/metre, while that at Davos in Switzerland is but 64 v./m. Over the oceans a value of 126 v./m., which varies little if at all with geographical position, has been found. The average value for the whole earth is not far from 120 v./m.

It would seem that the potential gradient observed on land is not a quantity of much fundamental significance, its value depending primarily upon local conditions of atmospheric conductivity. This is evident from the fact that a simple periodic variation according to *local* time is the basis of all fine-weather land records. The minimum values are obtained in the early morning at about 4 a.m. and the maxima in the evening between 6 and 8 p m. In many places a second maximum at 8 a.m. and a second minimun at midday are found. The amplitude of these daily variations at land stations sometimes reaches 50 per cent. of the mean value for the day.

The local time variation has been shown by Whipple[3] to be closely correlated with the amount and distribution of the smoke pollution of the atmosphere near large cities, where these continuous records have generally been made. Fig. 12 shows the variation at Kew of the potential gradient during the summer months for the two periods 1898-1915 and 1916-28, together with the variation in the amount of pollution (determined by aspirating the air through filter-paper) for the period 1921-28. The figure shows not only the close relation which exists between potential gradient and pollution but also the striking effect of the introduction of " summer time " into Great Britain in the year 1916, after which the morning minimum and maximum moved back by approximately one real hour. The atmospheric pollution curve has maxima and minima which have been explained by Simpson as due to the combined effect of variations in the amount of smoke produced in the city and variations in the stability of the atmosphere, that is in the mixing action of surface winds and general turbulence of the lower air.

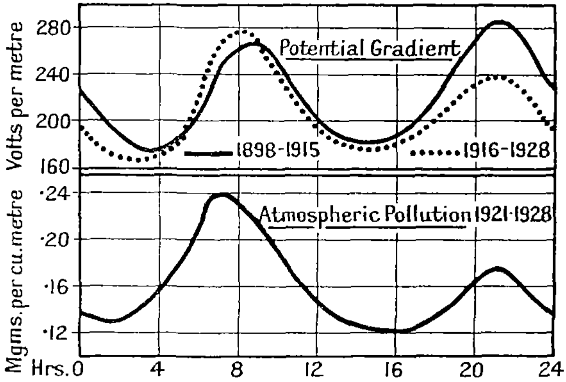

FIG. 12.—Relation between potential gradient and atmospheric pollution (Whipple).

As regards the annual variation of the potential gradient, land stations in both hemispheres show a maximum in the local winter and a minimum in the local summer. The only significant exception is the Antarctic region, where a reversal of phase occurs, giving rise to a maximum in the local summer and a minimum in the winter.

In view of the local origin of the variations of the gradient found at land stations near towns, observations over the oceans, where no pronounced local effects are to be expected, are of very great importance. Mauchly[4] has analysed the measurements of the *Carnegie* cruises and found that there is a well-marked diurnal variation at sea, with maxima and minima occurring at the same moment in all parts of the globe. Thus the potential gradient in all oceans is found to be about 15½ per cent. below the mean at 5 hours, Greenwich Mean Time, and about 20 per cent. above it at 19 hours, G.M.T. It is remarkable that the same 24-hour wave, progressing according to universal solar time, has been observed by expeditions to the Arctic and Antarctic regions and to Lapland. Fig. 13 (*a*) (after Whipple) illustrates these results, which have been confirmed by the last cruise of the *Carnegie*. In each case shown in the figure, the mean potential gradient has been reduced to 100 v./m. No appreciable annual variation has so far been observed over the sea.

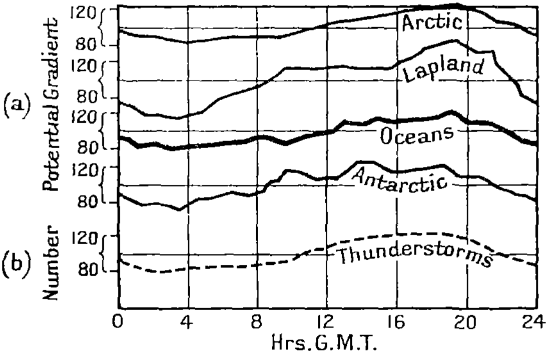

FIG. 13.

(*a*) Variation of potential gradient with universal time.
(*b*) Variation of thunderstorm activity over the earth's surface (Whipple).

Mauchly's discovery of a variation of potential gradient according to universal time is generally accepted as being of fundamental significance. The variation must clearly be ascribed to an alteration in the difference of potential between the upper conducting layers of the atmosphere and the earth ; it affords an important means of testing any theory of the origin and maintenance of this potential difference.

§ 28. THE FINE-WEATHER CURRENT : CONDUCTION AND CONVECTION CURRENTS

In the ordinary fine-weather field positive ions are driven towards the earth and negative ions away from it; the motion of these ions constitutes a downwardly directed conduction current. We have seen (§ 3) that the conduction current passing through 1 sq. cm. of a horizontal plane is given by $I_0 = F(\lambda_+ + \lambda_-)$, where F is the strength of the electric field and λ_+ and λ_- are the polar conductivities of the air at the point in question.

There is, however, a fine-weather current of a different nature which plays a part in the transfer of electricity by the atmosphere. If the air should contain at any point an excess of ions of one sign (a space-charge), movement due to wind or ordinary turbulence will give rise to a mechanical transference of electric charge. Thus if v is the upward vertical component of the velocity of the air and ρ the space-charge per c.c., the upward convection current due to this cause will be $v\rho$ per square centimetre. The real current-density in fine weather is thus the resultant of the downward conduction and the upward convection currents, and is given by $I = I_0 - v\rho$.

The mean value of the total fine-weather current is not far from 2×10^{-16} amperes per square centimetre or 2 microamperes per square kilometre, so that the total current flowing in this way between the upper atmosphere and the whole earth is about 1000 amperes. It would seem, from measurements which have been made in various parts of the world, that this current varies much less with changes in geographical position, in time of day and season of the year, than does the potential gradient. Although in the past it has not received a great deal of attention, it would appear to be a more fundamental quantity than the potential gradient and less affected by purely local conditions.

§ 29. Direct Determination of the Conduction Current at the Surface of the Earth

Direct measurements of the magnitude of the conduction current which flows into the earth's surface have been made with the Wilson universal electrometer, with the test-plate mounted flush with the surface of the ground, as described in § 23. The curve of Fig. 14 illustrates the procedure followed in the measurements. At time t_1 the test-plate is exposed to the earth's field by removing the cover, and the capacity of the compensating condenser is adjusted to the value C necessary to bring the gold leaf back to the zero position. The

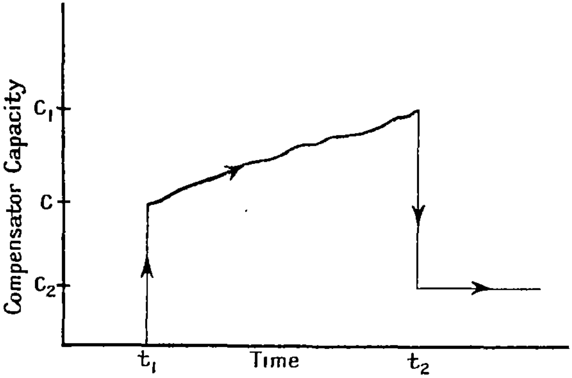

Fig. 14.—Measurement of conduction current with the Wilson universal electrometer.

charge on the plate is then $-$ CV and the field strength $F = 4\pi\frac{CV}{A}$, where, as before, A is the area of the plate and $-$ V the potential of the outside of the compensator. The test-plate is now left exposed until time t_2 and kept continuously at earth potential by increasing the compensator capacity to balance the charge received from the positive ions driven from the air on to the plate. Owing to variations in the strength of the field, and so in the induced charge on the plate, this increase is not a regular one. At time t_2 the plate is again shielded with the cover and the compensator capacity is reduced from C_1 to C_2 to maintain the shielded system at earth potential. At this moment the field strength is $4\pi(C_1 - C_2)V/A$. Since at the beginning of the measurement the compensator capacity was zero, it is evident that during the interval, $t_2 - t_1$, the plate received a positive charge C_2V and the average value of the conduction current per square centimetre was $C_2V/A(t_2 - t_1)$. For routine observations the instrument is mounted on a tripod above the ground, and the readings are reduced to standard conditions by occasional determinations of the reduction factor, from observations in a pit.

§ 30. Indirect Determination of the Conduction Current at a Point in the Air

The conduction current at a point in the air can also be determined by separate measurements of the field strength, F, and the polar conductivities, λ_+ and λ_-. The methods used to determine F, or the potential gradient, have already been described in this chapter; the conductivities are usually found by the Gerdien method sketched in § 2. In another form of the Gerdien method, due to Schering, the cylindrical condenser is replaced by a large earthed wire cage, along the axis of which is a charged insulated wire connected to an electrometer. The rate at which the charge is dissipated by ions of opposite sign is determined in exactly the same manner as in the Gerdien method, and the same equations apply if certain conditions are fulfilled. The cage must be large enough, and the charge on the wire small enough, to ensure that no considerable alteration in the number of ions is caused by the flow of current. The arrangement must be set up in the open air to ensure that ordinary atmospheric circulation prevents the development of the electrode space-charges to be described in the next section. And finally the whole cage must be shielded from the earth's field by a rough roof or by trees, otherwise it will carry an induced negative charge on the outside and rob the air entering it of negative ions.

§ 31. THE COMPARISON OF THE DIRECT AND INDIRECT METHODS: ELECTRODE SPACE-CHARGE

The direct method due to Wilson measures the conduction current entering the earth; the indirect method measures the current at a certain height above the earth. In the latter case the current is carried by two oppositely moving streams of ions of opposite sign; in the former it consists of a single stream, for while positive ions enter the earth, negative ions do not pass from it into the atmosphere. The two methods, therefore, do not measure the same thing. One determines the true conduction current at a height, and the other its positive component at ground-level.

Consider a vertical cylinder of perfectly still air whose height is h and cross-section 1 sq. cm., with its base on the ground (Fig. 15). Let F' and F be the electric field strengths at top and bottom of this cylinder, and λ'_+, λ'_- and λ_+, λ_- the polar conductivities. The conduction current through the top is $F'(\lambda'_+ + \lambda'_-)$; a positive charge $F'\lambda'_+$ enters, and a negative charge $F'\lambda'_-$ leaves, in each second. Through the bottom there is only a downward flow of positive ions, carrying away a positive charge $F\lambda_+$ per second. The cylinder as a whole thus loses a positive charge $F\lambda_+ - F'\lambda'_+$ per second, and a negative charge $F'\lambda'_-$ per second. This may be expressed as a development of a positive space-charge at a rate $F'\lambda'_- - (F\lambda_+ - F'\lambda'_+) = F'(\lambda'_+ + \lambda'_-) - F\lambda_+$ per second. The growth of this "electrode" space-charge will automatically decrease the field F′ and will cease only when F′ has such a value that as many negative as positive ions leave the cylinder in each second, i.e. when

$$F'(\lambda'_+ + \lambda'_-) = F\lambda_+ \quad . \quad (10)$$

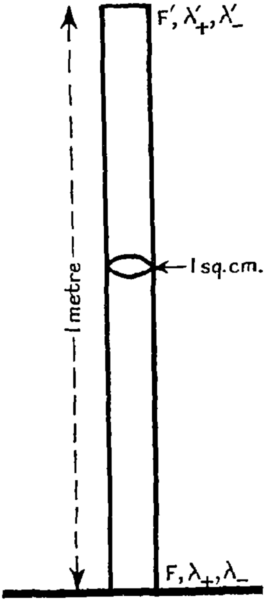

FIG. 15.—Electrode space-charge.

The two sides of this last equation are respectively the conduction currents at height *h* and at ground level. Thus, for perfectly still air, the two methods we have described should give the same numerical values, though they measure different quantities. It appears probable that this conclusion is not realised in practice and that the Wilson method yields much smaller values than the other. Some average figures from the more extensive series of measurements are shown in Table IV.

Still another consequence of the argument we have considered fails to appear in practice. Watson [1] has shown that during fine weather at Kew there is no sign of any electrode space-charge within the first metre above the ground, and that F′ and F are the same.

As there can be no doubt that a space-charge would develop if the air were perfectly still, it has been

TABLE IV

MEASUREMENTS OF THE AIR-EARTH CONDUCTION CURRENT

Indirect Method.		Direct Method.	
Station.	Current (amps./sq. cm.).	Station.	Current (amps /sq. cm.).
Potsdam	$2{\cdot}2\ 10^{-16}$	Kew	$1{\cdot}1\ 10^{-16}$
Davos	2·0 ,,	Munich (Lutz)	1·0 ,,
Gottingen	2·7 ,,		

suggested that ordinary atmospheric turbulence, by continually mixing the lower layers of the air, carries the excess positive charge upwards as rapidly as it is formed. If $F' = F$ and $\lambda'_+ = \lambda_+$, the positive charge developed in the cylinder per second is $F'\lambda'_-$. This must be removed by the air at such a rate that an upward connection current $v\rho = F'\lambda'_-$ per sq. cm. crosses the top of the cylinder, and the total resultant air-earth current at the height h is

$$I = I_0 - v\rho = F'(\lambda'_+ + \lambda'_-) - F'\lambda'_- = F'\lambda'_+ \simeq F\lambda_+.$$

If this view is correct, the quantity $F\lambda_+$, which is the portion of the conduction current measured by the Wilson method, is actually equal to the total current, conductive and convective, passing between the atmosphere and the earth. While this result may not hold in practice with great exactitude, the arguments outlined above indicate that the test-plate method gives a closer approximation to the total fine-weather current than the indirect method which determines the conduction current only. The test-plate result is the more valuable because it appears that any direct estimate of the convection current by itself is very difficult.

§ 32. VARIATIONS IN THE FINE-WEATHER CURRENT

Both direct and indirect methods of studying the air-earth current indicate that in fairly fine weather it is less subject to variations than is the potential gradient. Simultaneous measurements of the field and of the total conductivity of the air, $\lambda = \lambda_+ + \lambda_-$, show that these quantities vary to some extent in inverse ratio, with the result that their product, the conduction current, is less variable than either. Factors such as an increase in the number of condensation nuclei or the presence of fog particles, which decrease λ by raising the proportion of the slow ions present, cause a corresponding increase in the potential gradient. The simple form of the daily variation in the earth's field has its counterpart in an inverse variation of the conductivity, with a maximum in the early morning between 3 and 4 a.m. The extreme effect of atmospheric pollution near large cities, which increases the potential gradient and diminishes the conductivity, has already been discussed (§ 27). In general the reciprocal relation between λ and F is not exact enough to keep the conduction current invariable. At land stations in Europe it is found to have an annual variation which coincides in phase with that of the potential gradient but has a smaller amplitude. At most stations its daily variation follows the changes in the conductivity.

As shown by Table IV the mean values obtained at European stations for the conduction current, using the indirect method, all lie close to $2{\cdot}0 \times 10^{-16}$ amps./sq. cm. The observations over the sea and near the poles give about double this value. Since, as we have seen, to make allowance for the upward convection current near the ground these figures must probably be reduced by half, the total air-earth current in fine weather may be taken to have an average value of 2×10^{-16} amps./sq. cm. over the whole globe.

§ 33. THE CONDUCTION CURRENT AT GREAT HEIGHTS

It has been found from simultaneous determinations of potential gradient and atmospheric conductivity during balloon ascents that the rapid decrease in F with height above the ground is accompanied by an increase in λ, of such magnitude as to keep the conduction current approximately constant. Table V shows the results of an ascent by Wigand,[5] in which it will be seen that when the field had fallen to 1/14 of its value at the ground, the conductivity had risen eleven-fold.

TABLE V

CONDUCTION CURRENT DURING BALLOON ASCENT (WIGAND)

6500	8·8	12·6 ,,	1·2 ,,

§ 34. THE SIGNIFICANCE OF THE AIR-EARTH CURRENT

The general constancy of the air-earth current with height above the ground and in different parts of the world suggests that, at any rate to a first approximation, it has its origin in a constant potential difference between the conducting layers of the upper atmosphere and the earth, and that its actual value depends upon the resistance of the air between the two regions. Now the conductivity of the upper portion of this air-path is entirely due to the penetrating radiation * and is unlikely to alter at all with time of day, locality or season (§§ 20, 21). But below a height of about 2 kilometres over land

---

* This refers to the regions from 15 to 30 kilometres above the ground. The Heaviside layer 80 kilometres up has a solar origin.

areas, an additional ionising influence is exercised by radioactive matter in the air and the earth, which, as we have seen (§ 5), varies very much. Moreover, the conductivity of the air in this region is dependent upon the relative concentrations of the large and the small ions, and these alter with the number of nuclei present. The current-bearing column of air above the point of observation thus consists of an upper constant resistance and a lower variable one in series with each other. The extent to which the current carried by the air-column alters with local conditions will depend on the ratio which the lower variable resistance bears to the total resistance.

The conductivity above 14 kilometres is so high that we may, for the sake of illustration, suppose that this is the actual height of the upper positively charged layer and take the mean specific resistance of the air between it and the earth to be $7{\cdot}1 \times 10^{14}$ ohms-cm., the value found by Wigand at a height of 6·5 kilometres. Then the total resistance of an air-column of cross-section 1 sq. cm. would be 10^{21} ohms. If the variable part of the column be the first 100 metres above the earth, where the specific resistance is usually 8×10^{15} ohm-cm., this portion will contribute 8×10^{19} ohms to the total. We see that even if the conductivity of the first 100 metres were halved, the effect upon the air-earth current would amount to but 4 per cent. The potential gradient near the ground, on the other hand, would be doubled, for from this point of view it represents the fall of potential per unit length of the lowest part of the current-bearing column. It is evident that potential gradient measurements over land, and in particular near cities, cannot be expected to yield information which bears directly upon the question of the total potential difference between upper atmosphere and earth. In the case of observations at sea and in polar regions the position is different; practically all the ionisation throughout the whole column is then due to the penetrating radiation, and the only local effect which can influence the fine-weather gradient is a change in the number of nuclei available for the capture of small ions.

§ 35. The Electric Field during Disturbed Weather

The normal downwardly directed field, due to a positively charged upper atmosphere and a negatively charged earth, is frequently disturbed when the weather ceases to be fine. During fog, as explained in § 32, it is very much increased, and may reach ten times its normal value ; during dust-storms, of the type common in semi-arid regions and deserts, powerful reversed or negative fields are usual and reach 10,000 volts per metre. The effects found during cloudy weather and rain are variable, and range from gradients of the order of a few hundred volts per metre in a fine drizzle to as much as 50,000 volts per metre under thunderclouds.

Generally speaking, negative fields predominate when light or steady rain is falling, though occasional positive excursions are observed. In the case of heavy rainstorms and thunderclouds, the sign of the field depends upon the portion of the cloud passing over the point of observation, but here, too, there is evidence that negative gradients are the more frequent.

The field during thunderstorms fluctuates a great deal if the cloud is active in producing lightning. Its value at the ground does not as a rule exceed 10,000 to 20,000 volts per metre except for very brief intervals occupying fractions of a second. Equally high fields are observed during heavy rainstorms unaccompanied by lightning. During a snowstorm the field is usually positive and in a heavy storm may attain 10,000 v./m. The methods employed for the study of the large and rapidly varying fields of thunderclouds are described in Chapter IV.

§ 36. The Charge on Rain and Snow ; the Precipitation Current

The apparatus required to examine the charge carried to the earth by precipitation—rain, hail, snow, and sleet—is comparatively simple, and consists essentially of an insulated metal vessel to catch the rain, etc., and an electrometer to measure the charge received. Great precautions must, however, be taken to eliminate the disturbing effect of the negative charge given to the air as the drops splash on the container (Lenard effect, § 43). If some of this is lost a spurious positive charge will be indicated. For a similar reason, the entry of spray due to the splashing of rain falling outside the receiving vessel must be prevented. The receiver must be screened electrostatically from the electric field outside. The rate of rainfall, and sometimes the average size of the drops, is also observed ; with sensitive forms of the apparatus the charges carried by individual drops may be measured. As the charges brought down vary considerably, it is necessary in all such work to carry out a long series of observations.

Since the year 1908, when the modern series of observations began, all observers agree in finding a preponderance of positive charge on rain in general. The average ratio of the quantities of positive and negative electricity brought down by all kinds of precipitation varies according to the situation of the observer. Some of the values found for this ratio are : Potsdam (Schindelhauer), 1·4 : 1 ; Puy-en-Velay (Baldit), 2·4 : 1 ; Dublin (McClelland and Nolan), 4·8 : 1 ; Simla (Simpson), 2·4 : 1 ; Otago, New Zealand (Marwick), 3·2 : 1. As exceptions to the general rule, it may be noted that snow usually carries a considerable negative charge, and that the fine drops of a drizzle are also negative. Simpson showed in 1908 that thunderstorm rain—the most heavily charged of all forms—is positively charged when it falls from the front of the cloud and negatively charged elsewhere. Ordinary steady rain, unaccompanied by sudden changes in the barometer, shows the most regular as well as the highest excess of positive charge. If such rainfall alone is considered, Baldit's average ratio of 2·4 : 1 for all types of precipitation rises to 4·3 : 1.

The charge per c.c. in the case of heavy thunderstorm rains reaches average values of 30 to 40 e.s.u., while single drops may carry 100 to 200 e.s.u. (Gschwend) and attain potentials as great as 300 volts. The mean values reported by different observers for the nett charge per c.c. on all forms of precipitation during a long series of observations range from + ·029 e.s.u. at Potsdam (Schindelhauer) to + ·176 e.s.u. at Simla (Simpson).

The transfer of electricity from atmosphere to earth in this manner constitutes a "precipitation" current which appears on the whole to be in the same direction as the fine-weather conduction current, since it carries more positive than negative charge to the earth. In the case of thunderstorms this current sometimes reaches values as high as 2×10^{-11} amps./sq. cm., and the total convection current carried by the rain in such a storm may amount to more than 0·1 amp. Before it is possible to frame a trustworthy estimate of the amount of the excess of positive over negative electricity conveyed to the whole earth in this way, much more information is required from tropical and equatorial regions.

§ 37. CURRENTS DUE TO POINT-DISCHARGE

It is well known that an electric glow or brush discharge takes place from a pointed conductor when placed in a sufficiently strong field. It consists of a stream of ions of the same sign as the charge upon the point. Discharges of this kind must, therefore, be expected from the ends of exposed conductors on the surface of the earth whenever the potential gradient and the height and sharpness of the ends are sufficiently great. Indeed the earliest investigators, Franklin with his kite, Dalibard and Lemonnier with their high metal rods, detected electric fields, the first two in thundery, and the last in fine weather, by means of this current. Under favourable conditions, afforded by mountain peaks or the masts of ships exposed to the intense fields of a thundercloud, the glow discharge may become very conspicuous (St. Elmo's fire).

It was first pointed out by C. T. R. Wilson [6] that point-discharge currents of much smaller intensity must play an important part in the interchange of electricity between the earth and the atmosphere. The fields prevailing under rainstorms and thunderclouds very frequently reach values sufficiently great for considerable currents to be discharged from exposed conductors, such as trees, bushes, housetops and even fields of grass. A conductor need not end in a sharp point or project to a great height in order that it should begin to act as a discharger. For example, an earth-connected sphere of radius 1 cm. need only be raised to a height of 3 metres in the not unusual field of 10,000 volts per metre for the electric intensity at its surface to reach the critical value of 30,000 volts per cm. at which brush discharge begins. A practical instance of the correctness of this suggestion is afforded by some experiments made by the author, in which a small tree, 4 metres high, was cut off at its base, mounted on insulators and connected to earth through a galvanometer. Exposure to the fields due to nearby thunderstorms yielded the average point-discharge currents shown below:—[7]

TABLE VI

POINT-DISCHARGE CURRENTS FROM A SMALL TREE (SCHONLAND)

Field (Volts/metre).	Current (Microamperes).
– 3,500	0·07
– 5,500	0·20
– 11,000	1·00
– 16,000	4·00

The contribution of a single tree such as this must be multiplied by a very large factor to obtain the total current flowing between the earth and a thundercloud; in the case quoted, the tree was typical of the exposed natural conductors for many miles around, and a rough surface integration over the area affected by the cloud indicated that the total point-discharge effect was of the order of 2 amperes in an upward direction.

Since the direction and magnitude of the large fields associated with disturbed weather vary considerably, it is extremely important to know the relative amounts of positive and negative electricity discharged from an exposed point over a long period of time. In a series of observations by Wormell,[8] a sharp point carried on insulators at the top of a pole was connected by cable to one electrode of a voltameter filled with dilute sulphuric acid, the other electrode being earthed. The voltameter (Fig. 16) was constructed of fine capillary tubing (diameter 0·8 mm.) and the gases evolved were separately collected, their volumes being determined from the lengths of the bubbles formed. If v_1 and v_2 are the volumes of the mixed gases collected at the earthed and the point-connected electrodes respectively, the quantities of positive and negative electricity, q_1 and q_2, which have been discharged from the point can be separately determined in the following way: If one unit

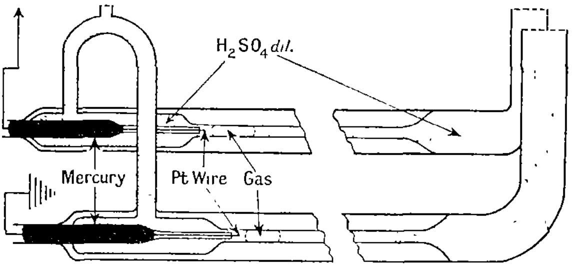

FIG. 16.—Water micro-voltameter (Wormell).

of quantity liberates in electrolysis c c.c. of oxygen and $2c$ c.c. of hydrogen, we have

$$q_1c + 2q_2c = v_1 \quad \text{and} \quad 2q_1c + q_2c = v_2,$$

from which we may determine q_1 and q_2.

The quantities discharged in this way have been examined by Wormell at Cambridge over a period of three years. Some of his results are shown in the table below :—

TABLE VII

INTEGRATED EFFECTS OF POINT-DISCHARGE (WORMELL)

Year	1927	1928.	1929.
Positive quantity discharged, q_1 (coulombs).	·28	·24	—
Negative quantity discharged, q_2 (coulombs).	·14	·11	—
Nett positive discharge, $q_1 - q_2$ (coulombs) .	·14	·13	·11

Each year shows a considerable nett loss of positive electricity by the discharger.

In a more detailed discussion it is noted that of 147 separate periods of disturbed weather accompanied by precipitation, 103 showed an excess of upward current (+ ve discharge), 34 an excess of downward current (— ve discharge), and in 10 the nett discharge was zero. This is what would be expected from the predominance of negative potential gradients in disturbed weather. It is to be hoped that similar measurements will be made in other parts of the world.

§ 38. The Interchange of Electricity Between the Earth and the Atmosphere; the Maintenance of the Earth's Charge

The negatively charged earth and the positively charged upper layers of the atmosphere form two plates of a spherical condenser with the lower air as the dielectric. Although the conductivity of the air between the plates is small, the applied potential difference is great enough to make the leakage of charge through it very considerable. The average value of the charge per unit area of the earth's surface is 9×10^{-14} coulombs/sq. cm., and that of the fine-weather conduction current is 2×10^{-16} amps. per sq. cm. Left to itself, a condenser of this kind would be discharged by internal leakage in a time of the order of ten minutes. But this is not all: to the dissipation of the earth's charge by the fine-weather current we must add the effect of the charge conveyed by rain and snow, for it has been shown that on the whole the nett charge conveyed to the earth by precipitation is positive in sign. Thus to the conduction current of 1000 amperes over the whole surface of the earth must be added a precipitation current in the same direction, estimated by Wigand[9]—though any such estimate can only be provisional—at 400 amperes, making a total of 1400 amperes tending to dissipate the 500,000 coulombs with which the earth is charged.

In spite of the continuous operation of these two factors, the earth's charge remains practically constant, so it is clear that there must exist some reverse or compensatory process which neutralises their effect. Some agency must be continuously at work replenishing the charges on the earth and in the upper air. The discovery of the mechanism responsible for this replenishment has been one of the chief problems of atmospheric electricity, and many suggestions have been made to this end. Two of these, though they have not proved acceptable, will be briefly mentioned.

The suggestion of Ebert is based upon the experimentally verified view that ionised air escaping through the narrow capillaries of the earth's crust is richer in positive than in negative ions, for the higher mobility of the negative ion causes it to diffuse more rapidly to the walls of a narrow passage. The air escaping from the earth and ionised by radioactive emanations, etc., thus gives a positive charge to the lower atmosphere, which Ebert suggested was conveyed to considerable altitudes by convection currents. It appears, however, that the Ebert effect in the lower atmosphere is actually extremely small and that the upward air-currents are quite insufficient to produce the necessary convection.

Another suggestion, made by Simpson and developed by Swann, is that negative charge is conveyed to the earth by fast-moving negatively charged corpuscles or β particles. This view meets with the difficulty that the ionisation produced in the air by the number of β particles needed to maintain the earth's charge would be very large, many times greater than that observed and known to be due to other causes. The objection can be avoided only by ascribing a very small ionising power to an extremely fast β ray (Swann). This is not in accord with what is known of the fastest β rays from radioactive substances, whose ionising powers vary very slowly with their energies.

It was first suggested by C. T. R. Wilson that it is to regions of disturbed weather that we must look for the mechanism of replenishment, that under rain and thunderclouds, where the potential gradient is more often reversed than in the normal direction, there are two processes at work which convey considerable quantities of negative charge to the earth. The first of these is the action of point-discharge from conductors projecting from the ground. This has already been discussed, and it has been shown that experimental tests indicate that it is of great importance. The second process is the charge conveyed to the ground by lightning flashes from thunderclouds. Every second, as will be seen in Chapter IV, some 100 lightning discharges occur over the whole surface of the earth, each involving the passage of a charge of the order of 20 coulombs. Only a fraction of these, perhaps one in four on the average, strike the ground. The effectiveness of this process of transference of charge will depend upon whether more charges of one sign than another are conveyed to the earth. If, for example, practically all the charges transferred were negative, the process would be equivalent to a continuous compensation current of about 500 amperes. Though there is evidence that this is actually the case, the question is still under investigation.

An estimate of the annual electrical " balance-sheet " of a square kilometre of ground at Cambridge has been made by Wormell,[8] on the basis of his point-discharge measurements and observations on lightning discharges. The air-earth conduction current loss and the effect of rain and snow were estimated from average values of these quantities. The results were :—

	Coulombs/sq. km /annum.
By natural point-discharge, gained .	−100
By lightning, gained	− 20
By atmospheric conduction, lost . .	− 60
By precipitation, lost	− 20
Nett gain of negative charge . . .	− 40

Though such an estimate is only a very rough one, it appears to be quite possible that in this locality the four processes approximately balance one another, or even that the earth gains a negative charge.

This suggestion of Wilson involves more than the interchange of electricity between the bases of cumulonimbus clouds, showers and thunderstorms, and the ground; he regards them as equally active in supplying positive electricity to the upper air. On this view the cloud acts as an electrical generator which removes positive electricity from the earth and supplies it to the conducting layers of the atmosphere above, by which it is rapidly distributed in such a way as to maintain them at a constant potential of about 3×10^5 volts, in spite of losses.

If this view is correct, we should expect the potential difference, and so the potential gradient, to show a maximum when the thundery regions of the earth are at their maximum activity.[10] The diurnal variation of the gradient discovered by Mauchly (§ 27) should agree in phase with the diurnal variation of thunderstorm activity over the earth. It has recently been shown by Whipple [11] that this appears to be the case. Whipple's examination of the diurnal variation of the world's thunderstorms is represented by the bottom curve of Fig. 13 (*b*), where it will be seen that the parallelism with the variation of the potential gradient over the oceans and the polar caps is indeed very close.

CHAPTER IV

THE ELECTRIFICATION OF THUNDERSTORMS

§ 39. The Number of Thunderstorms over the Globe

WHILE a thunderstorm is a comparatively rare event at any one station in temperate latitudes, the number of thunderstorms per day experienced by the earth as a whole is very large. Even in such a limited area as France there are comparatively few days in the year where thunder is nowhere reported. The total amount of thunderstorm activity which takes place at various seasons of the year has been determined by Brookes[1] from information taken from all parts of the world. According to his estimate, the earth experiences 16,000,000 thunderstorms per annum, or 44,000 per day. Taking one hour as the average duration of each—a modest estimate—there will on the average be 1800 thunderstorms in progress in different parts of the world at any one moment. In terms of lightning flashes this would mean that something like 100 flashes occur over the earth in every second, or 360,000 per hour.

It appears from recent measurements (§ 42) that the average thunderstorm develops and expends two or three million kilowatts of electrical energy continuously during its hour or two of activity. Over the whole earth, therefore, thunderstorms are continuously expending electrical energy at a rate of some 4×10^9 kilowatts. This figure is so large that by the employment of even a small fraction of its power in an apparently insignificant "side-line," the thunderstorm could be of importance in a number of geophysical problems. Amongst these may be mentioned the generation of Hertzian waves (atmospherics), the maintenance of the earth's negative charge and of the positive charge on the upper air (§§ 37 and 38), the production of high-speed electrons (§ 21), and of ionisation in the upper atmosphere.

§ 40. The Measurement of the Electric Fields and Field-changes due to Thunderstorms

Practically all the quantitative information on the electrification of thunderstorms which has so far been obtained has been derived from measurements of the electric fields and field-changes produced by them at the surface of the earth. The development of these measurements and the interpretation of the results obtained is mainly due to Professor C. T. R. Wilson.[2]

The general principle is similar to that of his test-plate or induced charge method of studying the fine-weather field (§ 23), in which an exposed conductor is kept at zero potential by alteration in the capacity of a compensating condenser, when the charge induced upon the conductor by the field is equal to that given by the compensator to the system. In the measurement of rapidly changing thunderstorm fields, however, compensation is produced automatically and practically instantaneously by means of an ingenious form of capillary electrometer. As shown in Fig 17, this consists of a small bubble of dilute sulphuric acid enclosed between mercury threads in a narrow capillary tube. The threads lead to end-cups of mercury, and one of these, A, is connected to a test-plate T insulated from, but flush with, the surrounding ground, while the other is connected to the earth. Between the mercury and the glass there is everywhere a thin film of dilute acid, so that an electrical "double layer" surrounds the mercury and makes each half of the electrometer a condenser charged to the potential difference of the double layer, about ·90 volt, the mercury being positively charged with respect to the acid. If a positive charge is given to the left-hand side, it will increase the charge on the left-hand condenser and the left-hand thread will move forward a certain distance so as to absorb this charge, by increasing the area of the acid-mercury surface and the capacity of the left-hand condenser. A corresponding movement of the right-hand thread causes a reduction in area on this side and the passage to earth of a quantity of electricity exactly equal to that originally supplied to the electrometer. The distance moved, y, is easily seen to be related to the charge passed through, q, by the equation

$$q = 2\pi r C V'(1 - r/R)y,$$

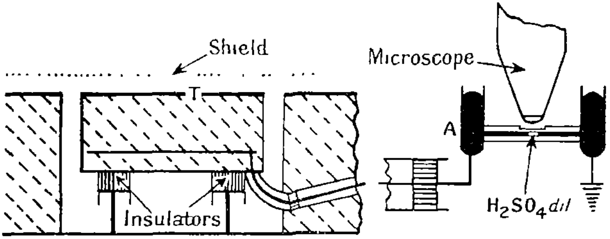

FIG. 17.—Measurement of the electric fields and field-changes due to thunderstorms (C. T. R. Wilson).

where r is the radius of the capillary and R that of the end-tube, V′ the potential difference, and C the capacity per unit area, of the double layer. Thus $q = ky$, where k is an instrumental constant which can be determined by discharging a known quantity of electricity through the instrument. The arrangement thus gives a linear relation between the movement of the acid bubble and the quantity discharged. In spite of the large value of C, about 30 microfarads per square centimetre, it is extremely sensitive. By using a microscope focussed upon one end of the bubble quantities of the order of 10^{-9} coulombs may be measured. A permanent record is best obtained by placing a slit and a moving photographic plate in the focal plane of the objective.

When connected to a test-plate the electrometer automatically maintains it at earth potential and records by its movements the quantities of electricity passing to and from the earth as a result of changes in the external field and of the induced charges on the plate. The type of record obtained from this arrangement during a thunderstorm is illustrated by the thick line of Fig. 18. An earthed cover is swung over the test-plate for a few seconds at the beginning of each minute, causing the movements A′AA″, B′BB″, etc., as the induced charge flows away to earth and then returns. The points A, B, C, E would lie on a horizontal line if there were no actual transfer of charge between the plate and the atmosphere taking place, that is to say, no conduction current, point-discharge, or transport of charge by rain. The first two minutes in the figure show the slight slope due to the conduction current only, the last two show the effect of a fall of positively charged rain. The charge, for example, conveyed to the

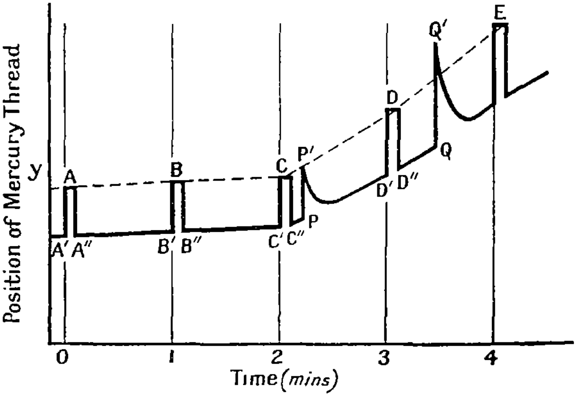

Fig. 18.—Capillary electrometer record during a thunderstorm.

plate by rain and conduction during the third minute is $k(y_D - y_C)$ and the mean value of the current per square centimetre $k(y_D - y_C)/60A$, where A is the area of the plate and k the constant of the electrometer. The dotted line joining the points A, B, C, D, E gives the reading of the instrument when the test-plate is shielded at any time during the record, and this line serves as the zero from which the field and field-changes are measured. The field at the end of the first minute, for instance, is given by $F = 4\pi k(y_B - y_{B'})/A$.

Two sudden interruptions in the record, such as are caused by lightning flashes, are shown at P and Q. At P the record suddenly touches the dotted line, indicating that for a moment the field was completely destroyed and the original induced charge ran to earth through the electrometer. At Q the movement extends beyond the dotted line, showing that the field was actually reversed in sign by the discharge and reached a reverse value equal to half its original strength. The shape of the record immediately after the passage of these lightning flashes, the recovery curve as it is called, is of considerable interest; it will be seen in these two examples that the thundercloud fields and charges recovered their original values after the lapse of something like twenty seconds. The rate of recovery was approximately exponential, being most rapid immediately after the flash and becoming very slow as the cloud approached its original electrified condition. We may find the magnitude of these sudden field-changes by the same method used for the field itself; if Δy be the movement PP′, or QQ′, the sudden field-change which caused it is given by: $\Delta F = 4\pi k \,.\, \Delta y/A$.

The test-plate arrangement, using a plate 50 cm. in diameter, is suitable for the measurement of fields of strength exceeding 1000 volts/metre, such as are caused by thunderstorms when they come within a distance of about 8 kilometres. For more distant storms Wilson employs a different form of exposed conductor, a copper ball 1 foot in diameter mounted on insulators at the end of an iron pipe 5 metres in length (Fig. 19). When the arrangement is in use the pipe is held vertical; by turning it about a horizontal axis through its base, the pipe is lowered and the ball enters an earthed metal case which shields it from the field. Connection to the capillary electrometer is made by an insulated wire passing down the centre of the pipe.

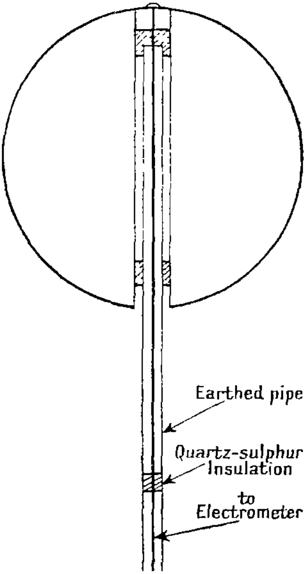

FIG. 19.—Elevated sphere for measuring fields of distant thunderstorms.

The field producing a given movement of the electrometer is calculated as follows: The charge q induced upon the ball when raised to a height h above the ground must be such as to maintain it at earth potential, for the ball is earth-connected through the electrometer. Thus if V is the undisturbed potential of the air at the point occupied by the centre of the sphere of radius r, we have $V + q/r - q/2h = 0$, the third term allowing for the effect of the electrical image of the charged sphere in the earth. If the movement of the electrometer caused by raising the ball from its case to the height h is y, we have $q = -ky$ and $V = k(1/r - 1/2h)y$. This observation therefore gives for the mean potential gradient between the ground and the height h,

$$F = V/h = (k/h)(1/r - 1/2h)y.$$

The same equation relates the sudden changes of field ΔF to the corresponding sudden movements Δy of the electrometer. Since these relations, like those derived for the test-plate, are derived on the assumption of a perfectly plane earth, small corrections must be applied to allow for the effect of the concentration of the lines of force upon the hut used to house the recording instrument.

The effects obtained from the elevated sphere become too small for accurate measurement when the storm is more than 20 kilometres away ; for still greater distances a wireless aerial has been used by some workers. Thunderstorm fields are of the same order as the fine-weather field, about 100 v./m., when the cloud is 20 kilometres off. At distances of 6 to 8 kilometres they often reach 5000 v./m., and when the storm passes overhead values of 10,000 to 20,000 v./m. are commonly observed, while the sudden changes may exceed these figures very considerably for a small fraction of a second. In an active thunderstorm the fields are constantly altering as a result of the neutralisation of part or all of the charge by lightning discharges, of the subsequent rebuilding of the destroyed charges, and of movements of the cloud as a whole.

§ 41. THE CHANGES OF FIELD ACCOMPANYING LIGHTNING DISCHARGES

The methods described have been used for the measurement of the field-changes due to lightning in England and in South Africa,[2, 3] and have led to valuable information as to the magnitude of the electrical quantities involved in the thunderstorm and the distribution of the charges in the cloud. The principles to be followed in the interpretation of the observations have been very completely discussed by Wilson.[2] Their application is not always an easy matter, for though the structure of most thunderclouds may be the same in principle, meteorological conditions lead to frequent departures from any simple model which can be framed. Anything like a full discussion of this question would occupy too much space, and so we will limit ourselves to the detailed consideration of a type of lightning discharge which takes place within the thundercloud without reaching the ground and which is the most frequent kind of flash in a tropical storm. In the Cape Province of South Africa nine-tenths of the discharges are of this nature, and simply involve the downward movement of a positive charge from a height of 4 or 5 kilometres to one of 2 or 3 kilometres.

Consider a simple cloud-model in which a positive charge Q is distributed through a spherical region with its centre at a height H_2 above the ground. To calculate the resulting downwardly directed field at the earth's surface we may regard the charge induced on the conducting earth as replaced by the image-charge — Q at a depth H_2 below the ground and we may disregard the curvature of the earth. The field at any point such as P (Fig. 20), at a horizontal distance L, is then that due to an electric doublet of moment $2QH_2$, and its strength is given by $F_2 = 2QH_2(H_2^2 + L^2)^{-3/2}$, vertically downwards. If a lightning discharge causes the positive cloud-charge to pass to a lower level H_1, the new field $F_1 = 2QH_1/(H_1^2 + L^2)^{-3/2}$ and the sudden field-change due to the discharge is

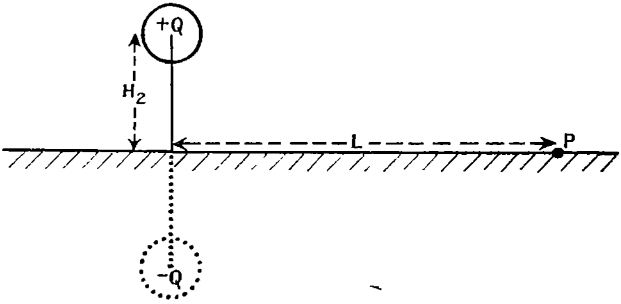

FIG. 20.—Thundercloud charge above the earth.

$$\Delta F = F_1 - F_2 = 2Q[H_1(H_1^2+L^2)^{-3/2} - H_2(H_2^2+L^2)^{-3/2}]. \quad (11)$$

It may be noted that this equation applies equally well if the act of lowering the charge Q involves the neutralisation of an equal and opposite charge $-Q$ at the height H_1, for the effect of adding the field due to this charge to both F_2 and F_1 disappears in computing the field-change ΔF.

Equation (11) shows that the change of field should be zero at a distance L_0 such that

$$H_1/(H_1^2 + L_0^2)^{3/2} = H_2/(H_2^2 + L_0^2)^{3/2},$$

that it is negative for $L > L_0$ and positive for $L < L_0$. This reversal distance L_0 is found to be 6·7 kilometres, if H_2 and H_1 are 6 and 3 kilometres respectively.

South African thunderstorms show this reversal in the sign of the majority of the field-changes very clearly. The following Table[3] gives the results of observations upon some fifty storms, giving 2800 observed field-changes which were grouped as "distant" when more than 15 kilometres from the station and as "near" when within 7 kilometres; in many cases the same storm was observed in both groups.

TABLE VIII

SUDDEN FIELD-CHANGES DUE TO THUNDERSTORMS (SCHONLAND)

Distant Storms.		Near Storms.	
Positive ΔF.	Negative ΔF.	Positive ΔF.	Negative ΔF
250	2375	188	9

The phenomenon of zero values for the field-changes, due to discharges at the reversal distance, can only be observed in isolated instances. In practice, owing to the discharge not taking a vertical but an inclined path, and for other reasons, the simple concept of a reversal point must be replaced by that of a reversal zone, in which small field-changes of either sign are equally probable, and which, in the storms of Table VIII, may extend from 7 to 15 kilometres from the point of observation.

When the distance L is great compared with the heights H_1 and H_2 of the cloud-charges, equation (11) takes an important form; it becomes

$$\Delta F = - 2Q(H_2 - H_1)/L^3 \text{ or } 2Q(H_2 - H_1) = - \Delta F \times L^3.$$

The quantity on the left is now the difference between the electric moments of the thundercloud charges before and after the discharge; it is referred to as the electric moment of the discharge. All that is needed to determine it is a measurement of the field-change due to a distant lightning flash and of the distance L, which can be found from the interval between the flash and the thunder it causes.

Measurements of the electric moments of discharges have been made both in England and South Africa, with similar results. The average value found is about 2×10^{16} e.s.u. × centimetres, or 60 coulomb-kilometres, in Europe, and 90 coulomb-kilometres in the more elevated tropical storms. Direct observation in the latter case gives for the vertical lengths of cloud-flashes, $H_2 - H_1$, values lying between 1·5 and 3 kilometres, so that the average quantity of electricity conveyed by a lightning discharge is about 20 coulombs. The usual range of variation for individual discharges is not large, from 2 to 100 coulombs if the length of the discharge is supposed constant, and probably much less if this quantity were actually observed in every case.

§ 42. MAGNITUDES OF THE ELECTRICAL QUANTITIES INVOLVED IN THUNDERSTORMS

The determination of the average quantity of electricity destroyed by a flash of lightning provides the starting-point for the evaluation of a number of important electrical quantities involved. A single flash, of the kind we have discussed, generally completely discharges

6

the whole cloud and momentarily reduces the field from it to zero. A fairly active cloud produces one flash every twenty seconds ; to feed the flashes such a storm would have to generate electricity at an average rate of 1 coulomb per second, i.e. the mechanism would have to provide an average current of 1 ampere. Reference has already been made to the rapid rate at which the initial regeneration of the cloud-charges takes place. It is usually such as to be able to restore the whole electrification in about five seconds if it continued for that time. The exponential form of the recovery curves suggests that this initial rate may remain constant, but that, as the cloud charges grow, effects occur which tend to dissipate them and which are proportional to the quantity of charge present at any time. On this view the rate of regeneration involves a current of 20/5 coulombs/sec. or 4 amperes. The electrical energy generated by the storm is thus only partially employed in the feeding of lightning flashes ; at the moment just before a discharge most of the power of the machine is being expended in overcoming various leakage effects. It may happen in this way that the field in the cloud never reaches the sparking value : this appears to be the case in many heavy rainstorms.

Before proceeding further it is necessary to know the critical value of the electric field strength at which the spark which we call lightning takes place. In air at ordinary pressure this is 30,000 volts per centimetre, but in a thundercloud the pressure is lower and the presence of small drops of water introduces a new and important factor. Macky[4] has recently investigated the behaviour of water-drops in strong electric fields, and finds that when exposed to increasing fields a drop of radius r cm. becomes elongated, until at a definite field strength, given in volts per cm. by $F\sqrt{r} = 3875$, it becomes unstable and filaments are drawn out from the ends. When instability occurs, a discharge passes through the drop in exactly the same manner as it would through a conductor pointed at both ends, with characteristic luminous glows. The fields producing discharge through the drops are unaltered by reduction of the air-pressure over a wide range ; for example, the field required to cause discharge through a drop 0·227 cm. in radius remains at 8400 volts/cm. as the pressure drops from 76 to 25 cm. of mercury. At still lower pressures the discharge is unaffected by the drop and the sparking potential falls in the usual way. The removal of water by the formation of filaments sets a limit to the size of the drops which can exist inside a thundercloud. Macky concludes from his experiments that no drops larger than 0·15 cm. in radius can be present in the fully charged cloud, and that the critical value of the field at which breakdown occurs is of the order of 10,000 volts/cm. or 33 e.s.u.

With this information the potential and the volume of the charged portion of the cloud can be estimated. Although the results might be expected to depend very much upon the manner in which the charge is distributed, it appears that whatever assumptions are made on this point the values obtained are of the same order of magnitude. Consider a simple spherical distribution of a charge q on a sphere of radius R . the electric field at the surface of the sphere is given by $F = q/R^2$, and at the moment at which a discharge takes place q is 20 coulombs or 6×10^{10} e.s.u. while F has the value 33 e s.u. Hence $R = 427$ metres and the dimensions of the charged region are of the order of 1 kilometre. The potential at the surface is given by $V = q/R = FR = 33 \times 4{\cdot}3 \times 10^4$ e s.u. or $4{\cdot}3 \times 10^8$ volts. If the radial electric force within the sphere everywhere reaches the sparking limit, the potential at the centre is 2FR or 9×10^8 volts. Two such spheres carrying opposite charges would therefore be at a difference of potential of the order of a thousand million volts.

A similar result follows if we make the very different assumption that the two poles of the cloud are distributed in horizontal layers with a vertical thickness L of neutral water-drops between them. The order of magnitude of

L is known from the lengths of lightning discharges to be 2 kilometres, and the critical value of the field, as we have seen, is 10,000 volts/cm. Thus the difference of potential between the poles is $10.000 \times 2 \times 10^5$ or 2×10^9 volts.

When a cloud-charge is conveyed to earth, or neutralised by another charge of opposite sign, by a lightning discharge, the energy dissipated is of the order of 2×10^{17} ergs or 5×10^9 calories; most of this is converted into heat along the path of the lightning flash. A cloud giving one flash every twenty seconds is dissipating electrical energy in the form of lightning at an average rate of 10^6 kilowatts. We have seen that other effects may account for an expenditure of energy at a rate considerably exceeding this.

§ 43. The Distribution and Origin of the Electric Charges

It is generally agreed that the seat of the generation of the electricity of a thundercloud lies within the cloud itself. Equal quantities of positive and negative electricity are produced and then separated by some agency into different regions, where they constitute the "poles" of the electrical machine. During the period in which the charges are built up the dissipation losses in these two regions may well be quite different and the quantities ultimately collected upon the two poles are not necessarily the same. The distribution of the charges has been the subject of a great deal of investigation, both practical and theoretical. At the present time two quite different views as to the distribution and the mechanism which gives rise to it, suggested by G. C. Simpson and by C. T. R. Wilson, are being examined.

According to Wilson the polarity of a thundercloud is what is called positive, the positive pole being higher up in the cloud than the negative one. The cloud is to be considered as made up of large negatively charged drops and small positively charged droplets.[5] When a flash of lightning has just removed the free charges at the poles, the situation is momentarily that illustrated by Fig. 21 (*a*), in which the cloud as a whole is electrically neutral. Immediately afterwards, however, the faster rate of fall under gravity of the large negative drops leads to the development of free positive and negative charges at the top and bottom of the cloud, separated by a neutral region, as represented in Fig. 21 (*b*). Since the free poles attract each other, the rate of separation will become slower as the charges grow and will lead to a rate of fall of the larger drops which is just sufficient to maintain the charges at their existing values, in the face of the dissipating action of point discharge currents within and outside the cloud. Ultimately the field between the poles may become strong enough for a discharge to pass. If the charges are equal, this leaves the cloud in its initial state and the large drops in the neutral region once more separate under the action of

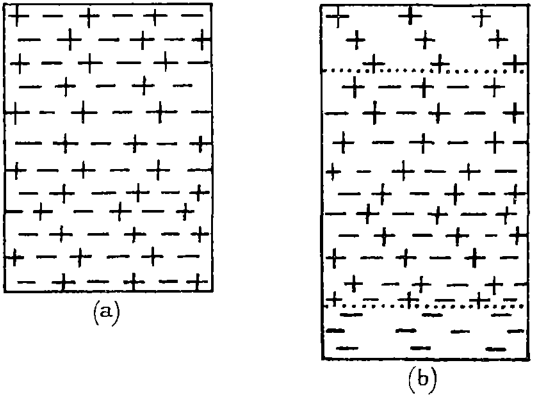

FIG. 21.—Distribution of thundercloud charges (C. T. R. Wilson).
(*a*) Just after a lightning flash.
(*b*) Just before a lightning flash.

gravity. The relative rate of separation may be taken from Macky's results, already discussed, to be the terminal velocity of a drop 0·15 cm. in radius, which is about 6 metres per second. Relative to such a drop the much slower small droplets may be considered as stationary. The average rate at which the initial regeneration of the moment of the cloud takes place is 60/5 coulomb-kilometres per second, using the data given in § 42. From these figures Wilson[5] finds that the average total charge on the positive or negative carriers in the neutral part of the cloud is about 500 coulombs, occupying a volume of some 4 cubic kilometres. The charge per cubic centimetre of water on the larger negatively charged drops he finds to be less than 30 e.s.u., a result which we have seen (§ 36) to be in accord with direct measurements of the charge on rain from thunderstorms.

The mechanism suggested by Wilson as the cause of the opposite charges on large and small drops depends upon the presence in the cloud of numbers of slow ions, attached to Aitken nuclei and small water-drops. Since their mobility (§ 1) is about ·0003 cm./sec., the velocity with which these ions will move, even when the field attains its maximum value of 10,000 volts per metre, is only 3 cm./sec., which is less than that of a drop of water a few thousandths of a centimetre in radius falling under gravity. In the earliest stages of the development of the charged cloud, these may arise from natural sources, but later on they will be supplied in enormous numbers by brush-discharge from water-drops drawn out by the field into pointed forms.

Consider a large drop, say 1 mm. in radius, inside a cloud in which a strong downwardly directed field already exists. Owing to this field, the drop carries a negative polarisation charge upon its upper surface and a positive charge below (Fig. 22). As it falls downwards, it will interact with positive ions moving more slowly down and with negative ions moving up; encounters with other charged drops will be relatively rare. The polarisation charge on the drop and the fact that its velocity, 590 cm./sec., is large compared with that of the slowly moving ions, will cause it to behave differently in its encounters with the two streams. At its under-surface a selective capture of negative ions will occur, for the negative ions which it meets will be attracted and the positive ions repelled by the positive polarisation charge there. A reverse process, a selective capture of positive ions, does not, however, take place at the upper surface, for here the drop is receding from the ions and the positive ions have been repelled away from the drop at the earlier encounter. Innumerable episodes of this kind will lead to the acquisition of a considerable resultant negative charge by the drop from the ion-streams, without seriously affecting the possibility of further captures. For example, a drop 1 mm. in radius falling in a field of 10,000 volts/cm. carries at each end a polarisation charge of ·25 e.s.u. and if it had collected a nett charge equivalent to the very reasonable value of 12 e.s.u. per cubic centimetre of water (§ 36), the negative ions captured would only increase the upper negative and decrease the lower positive charges by 10 per cent.

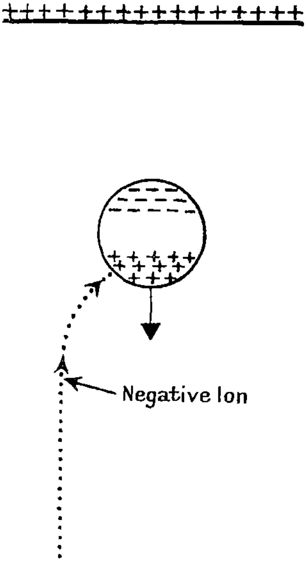

FIG. 22.—Capture of negative ions by large falling drops.

The tiny droplets in the cloud, which are falling with a velocity of the same order as that of the ion-streams, would be unable to exercise the selective action described; they will therefore acquire a nett positive charge, the complement of the negative charge collected by the larger drops.

A complete account of this theory has not yet been given; it would involve consideration of the early stages in the building up of a charged cloud, the action of the normal potential gradient of fine weather in determining the direction of the field to be generated, and the initial building up with the aid of natural ions.

A very different view of the origin and distribution of thundercloud charges has been developed by Simpson,[6] who considers the generation of the electricity to be a consequence of the disruption of rain-drops. Lenard showed in 1892 that when pure water splashes against a solid obstacle the water becomes positively charged, while a complementary negative charge is given to the air. Simpson in 1908 extended these experiments to the breaking of drops in an ascending current of air and obtained the same result, and quantitative values for the charge developed in the process. In extending this observation to conditions within a thundercloud, account has to be taken of the fact that a water-drop of radius greater than ·25 cm. becomes flattened out and unstable when it falls through the air, with the result that it breaks up into a number of smaller drops. Since the terminal velocity of fall for a drop ·25 cm. in radius is 8 metres per second, it follows that no drops of water can ever fall downwards through an ascending current of air whose vertical velocity component exceeds 8 metres/sec. All drops of water under such circumstances will be carried upwards.

The meteorological conditions inside a thunderstorm of the heat-type are represented by Simpson as in Fig. 23; the continuous lines represent stream-lines of the air, and their distance apart is made inversely proportional to the wind-velocity at each point. The air enters the cloud from the right and passes upwards into the front of the cloud. The vertical component of the velocity of the wind is taken to reach a value exceeding 8 metres per second within the oval unshaded region. No water, as we have seen, can pass vertically downwards through this region. The paths of the larger drops, as they fall through the cloud, are represented by the dotted lines. On the right-hand half of the figure these drops are deflected to the left by the air-stream. Above the oval region, therefore, there will be a considerable accumulation of water, and it is here that the larger drops will form and break up on account of instability, giving rise to electric charge. The largest drops, ·25 cm. in radius,* will be falling fast enough to penetrate to just above the forbidden oval, where they will be broken into pieces by the upward-moving air. The fragments, now positively charged, re-form drops and fall back again, and the negative charge given to the rising air will be absorbed by small droplets and carried to the main body of the cloud. The region in which the process of generation of electricity occurs is indicated by the heavily shaded area above the oval.

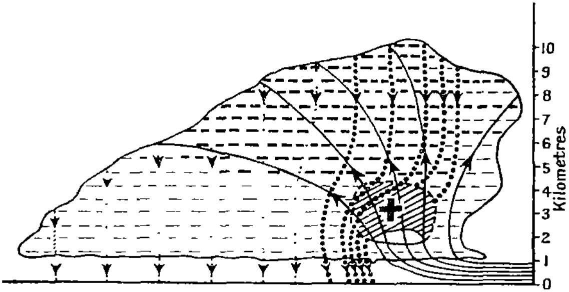

FIG. 23.—Thundercloud electrification (Simpson).

Simpson shows that a reasonable estimate for the average mass of water in the shaded region is 3×10^{11} grams, the dimensions of the region being of the order of a kilometre. If at any one time half this water is in the form of drops large enough to be broken up, the total number of drops available for breaking is $2{\cdot}2 \times 10^{12}$. Since the laboratory experiments showed that a drop of radius ·25 cm , when broken, gives rise to $5{\cdot}10^{-3}$ e.s.u. of charge, the quantity developed if every available drop broke once would be 3·6 coulombs. The drops would have to break six times to produce the 20 coulombs on the poles of the cloud.

---

* The theory in this form was put forward before Macky's results (§ 42) were published.

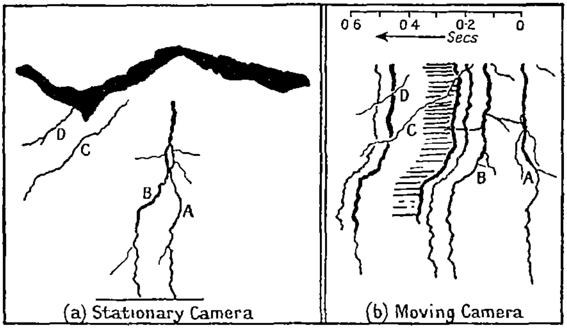
To decide between these two views on the charge distribution, various experimental tests have been applied to thunderclouds, the description of which is beyond the scope of this book. For the discussions on this question, the reader may be referred to the references at the end of the chapter[2, 3, 6, 7, 8, 9]. It is not impossible that both the Simpson and the Wilson mechanism may be at work in a thundercloud at one and the same time.

§ 44. LIGHTNING

Studies of the lightning discharge are of considerable interest in relation to the problems just discussed; they also furnish valuable material for the study of the spark discharge in air at ordinary pressures, over the mechanism of which general agreement has not yet been reached.

When photographs of the lightning channel taken on a moving camera are examined, they show that many apparently continuous discharges are made up of a number of separate strokes, separated by short periods in which faintly luminous channels sometimes continue. These discontinuities are often apparent to the eye as flicker of the flash of lightning. Though the whole flash often occupies more than a second, the component strokes are generally over in a few thousandths of a second. After each such stroke, the ionisation in places along its track persists sufficiently long to provide the succeeding stroke with a ready-made conducting path. Fig. 24 (after Walter)[10] illustrates how the apparent branching of a flash observed by the eye (24 (*a*)) is often the result of the superposition of a number of separate strokes, whose tracks coincide in part. Fig. 24 (*b*) is from a photograph of the same flash as (*a*), taken on a rotating camera.

These discontinuous strokes must arise from discontinuities in the rate at which the thundercloud can supply electric charge to the end of the channel. Since the cloud itself, though charged, is only a conductor by virtue of the ions produced by point-discharge from drawn-out water-drops, the conditions within the cloud, during the passage of a discharge, must be very complex.[11]



(a) Stationary Camera (b) Moving Camera

FIG. 24.—Component lightning strokes (Walter).

The field-change apparatus of Wilson, in the form described, does not usually yield information as to the quantities of electricity conveyed by these component strokes, the recording arrangement being too slow to record them separately. The results given in § 41 refer to the total integrated field-change and so to the total charge transferred by the flash.

§ 45. OSCILLATIONS IN THE LIGHTNING STROKE

Much attention has been paid to the question as to whether a lightning discharge is oscillatory or aperiodic, and several writers have examined the applicability of the well-known theoretical condition for aperiodicity, $R^2 > 4L/C$, where R is the total resistance of the circuit, C the capacity and L the inductance. The thundercloud itself is considered by some as a condenser plate whose capacity to earth can be estimated from its dimensions, by others as a non-conductor. Simpson,[11] who takes the latter view, has pointed out that the conducting channel of the flash, with its ramifications and tributaries within the cloud, is a conducting system possessing distributed capacity and self-inductance. He has shown that a straight lightning channel 2 km. high and 5 cm. in diameter will be capable of oscillation if its total resistance is less than 2000 ohms, or 1 ohm/metre. A potential difference of 10^9 volts applied to a channel of this resistance would give rise to a current of 500,000 amperes; there is evidence that momentary currents as large as this do actually flow.

On this view the oscillations may be expected to take the form of ripples superimposed upon the main current, without reversing its direction of flow. Such ripples have been observed by several workers (Appleton, Watt and Herd[7]; Norinder[14]; Mathias[20]) who have used the cathode-ray oscillograph to record the field-changes due to distant lightning flashes. The main effect is a unidirectional pulse which rises to a maximum and then falls to zero. On this are superimposed ripples which have a frequency corresponding to a wave-length in air of about 30 km. If the lightning channel be regarded as a gigantic wireless aerial 3 km. high, connected to earth at its base, its natural wave-length would be 12 km. Since the actual channel has extensive branches within the cloud, the agreement with the observed wave-length as regards order of magnitude can be considered satisfactory.

§ 46. THE ELECTRICAL EFFECTS OF DIRECT STROKES

We have seen (§ 42) that the potential of a thundercloud pole is about 10^9 volts. An elevated and insulated conducting system when struck by lightning may be expected to attain a considerable fraction of this potential. Experiments of this nature have been made by Brasch and Lange,[12] who used a wire stretched across an Alpine valley and insulated at each end. They have reported potentials of about 10,000,000 volts, giving sparks to earth 18 metres long. Pittman and Torok,[13] using a cathode-ray oscillograph connected to an overhead power line, have recorded a potential of 5,000,000 volts caused by a travelling wave from a lightning stroke which hit the line four miles away.

The time occupied by a lightning stroke is an important quantity in connection with the current in the discharge. Measurements by Norinder,[14] Mathias [20] and Watson-Watt [7] agree in giving values of the order of ·001 second for the duration of single strokes. Since we know from the work of Wilson that the average quantity of electricity carried by the stroke is about 20 coulombs, the average value of the current must be of the order of 20,000 amps. One would, however, expect that for very short periods of time the discharge current is much greater than this average. Lightning strokes to the supporting towers of power transmission lines have been found to carry currents as high as 250,000 amps.

The question of the diameter of the discharge channel has been the subject of laboratory experiments by Petersen,[15] who has found that powerful spark discharges carrying currents of the order of 60,000 amps. have a constant current-density of 10 amps. per square millimetre. If this result may be extrapolated to currents of 200,000 amps. it would yield 16 cm. for the diameter of the channel of a powerful lightning flash. The fulgurites formed by the fusion of sand struck by lightning have a diameter of some 5 cm., and Petersen reports that in his heavy current discharges the diameter of the channel at the electrodes contracted to one-third of its value elsewhere.

A simple and valuable instrument for the study of direct lightning strokes has been developed in America under the name of the Klydonograph. This is an adaptation of the well-known Lichtenberg figure experiment and operates as a recording voltmeter for high potential differences. The positive electrode (Fig. 25) takes the form of a rod A, touching the emulsion of a photographic plate or film. Below this is a thin layer of varnished paper insulation resting upon a flat metal plate connected to earth. When A is raised to a high positive potential a discharge passes along the photographic emulsion, which on development shows as a circular patch or figure. It has been found that the relation between the diameter of this figure and the applied voltage is a linear one up to potentials of 25,000 volts. Above this the instrument must be used with a potential divider, tapped off, for example, from a string of insulators connected between the elevated conductor and the earth. To measure negative potentials the connections must be reversed, the rod A earthed and the plate connected to the high potential side. For lightning recording, two oppositely connected klydonographs have been joined to the transmission lines under examination.

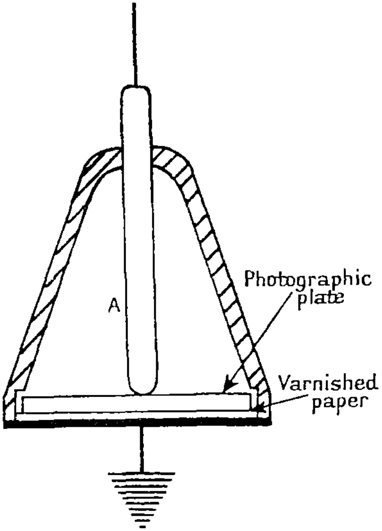


Fig. 25. — Klydonograph arrangement for recording potentials in lightning strokes.

Lewis and Foust [16] have recently published the results of some years' investigations with 1500 klydonographs connected to the supporting towers of transmission lines. One hundred direct strokes were recorded and all these conveyed negative charge from cloud to ground. This result is of interest in connection with the problems of the maintenance of the earth's charge (§ 38), and of the distribution of electricity in the thundercloud.

§ 47. The Mechanism of the Discharge

Two discussions of the actual mechanism of the lightning discharge have been given. Dorsey[17] considers that the principal factor is the movement of a stream of fast electrons from the negative pole, the ions necessary for the subsequent passage of the main discharge arising from the Townsend collision process. According to Simpson,[18] however, the discharge proceeds away from the positive pole; the slower-moving positive ions, on this view, constitute the tip or spear-head of the discharge as it develops, and the negative ions produced at the tip flow into the positive pole along the channel.

Light may be thrown on this important question, which is directly connected with the vexed problem of the mechanism of the electric spark between metal electrodes, by photographs taken with a camera moving sufficiently rapidly to show the manner in which the first stroke in a lightning flash proceeds. C. V. Boys[19] has developed a camera of this type and has published one such photograph. It shows a flash beginning at a point some 500 metres above the earth and developing its track simultaneously above and below.

UNITED STATES PATENT OFFICE.

LEE DE FOREST, OF NEW YORK, N. Y.

WIRELESS TELEGRAPHY.

No. 841,386. **Specification of Letters Patent.** **Patented Jan. 15, 1907.**

Application filed August 27, 1906. Serial No. 332,213.

To all whom it may concern:

Be it known that I, Lee de Forest, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented a new and useful Improvement in Wireless Telegraphy, of which the following is a specification.

My invention relates to wireless telegraphy and more particularly to an oscillation-detector which, in addition to performing the usual functions of such detectors, may be used as a tuning device and as a static valve, and which has a variety of other uses.

I have discovered that if the gaseous medium intervening between separated electrodes be put into a condition of molecular activity, as by heating the same or otherwise, said medium becomes highly sensitive to electrical oscillations, as more fully set forth in my application, Serial No. 243,913.

I have shown in my application, Serial No. 300,975, that the sensitiveness of an oscillation-detector comprising electrodes separated by such sensitive gaseous medium may be varied by the action of a magnetic field, so that the response of said detector *per se* is a function of a characteristic, such as the frequency, of the electrical oscillations operating upon the same. Thus, for certain frequencies a magnetic field of given strength will greatly decrease the sensitiveness of the detector and render it practically non-responsive, while for other frequencies the same magnetic field will greatly increase the sensitiveness of the detector. In short, said detector *per se* may be made selectively responsive without having recourse to tuned or resonant circuits, so that the use of such circuits may be dispensed with and the detector itself employed to perform the functions heretofore effected by said circuits.

The subject-matter of the present invention is an oscillation-detector which, like that above referred to, may be made selectively responsive to electrical oscillations having a given frequency or electrical rate of vibration but which does not require a proximate magnetic field for this purpose; and which also may be made selectively responsive to electrical oscillations having a given spark, or wave-train, frequency—that is to say, may be so adjusted that its response to electrical oscillations is a function of the number of groups or trains of waves per second, irrespective of the electrical frequency of such waves.

By virtue of the selective properties of my oscillation-detector as above set forth, I am enabled to employ said detector as a tuning device and also as a static valve or leak; and on account of its indestructibility I am enabled to employ the detector in those systems where large amounts of energy are created in the immediate proximity of said detector, such, for example, as the duplex systems described in my United States Letters Patent No. 772,879, dated October 18, 1904, and in the systems which permit "breaking" between two operators as set forth in my United States Letters Patent Nos. 827,523 and 827,524, dated July 31, 1906.

My invention may best be understood by having reference to the drawings which accompany and form a part of this specification and which diagrammatically illustrate four embodiments thereof which have successfully been employed; but I do not wish to limit myself to the details shown therein inasmuch as many other forms of construction and arrangement of circuits embodying the principles of my invention, as particularly pointed out in the appended claims, will readily occur to those skilled in the art.

In the drawings, Figure 1 represents a simple form of my oscillation-detector conductively connected with a receiving-antenna. Fig. 2 represents a detail of construction used in connection with the detectors shown in Figs. 1, 3 and 4. Fig. 3 represents a modification of the detector shown in Fig. 1 in which the detector is energized by an electric field developed by the oscillations to be detected. Fig. 4 represents a further modification in which the detector is energized by a magnetic field created by the oscillations to be detected.

In the figures, A is a receiving-antenna.

E is an earth connection.

M is a transformer, of which I_1 and I_2 are the primary and secondary windings.

B B′ are batteries.

R R′ are resistances.

L L′ are inductances.

T is a telephone or other signal-indicating device.

D represents an evacuated vessel of glass or other suitable material having two separated electrodes F and F′ between which intervenes the gaseous medium which, when sufficiently heated or otherwise made highly conducting, forms the sensitive element of my oscillation-detector. While various means may be employed for heating said gaseous medium I find it convenient to employ electrical means and, therefore, I prefer to employ as the electrode F a filament of carbon or metal and to connect the same in series with a battery B′ and a rheostat R′. I have ascertained that a filament of metal, especially one of tantalum, renders the oscillation-detector much more sensitive than one of carbon.

The electrode F′ may consist of a non-heated metallic body such, as shown in the present instance, as the wings or plates F′ F′ secured to the metallic base 2, which may be supported by the upwardly-extending portion 3 of the vessel D, although any suitable means may be used to support the electrodes F′ within said vessel.

While I have shown and described the electrode F′ as consisting of two wings or flat plates, it will be understood that said electrode may have any other form suitable for the purpose, although I have found that better results are obtained by using two flat plates or wings than by using a flattened cylinder and that a flattened cylinder gives better results than a cylinder of circular section. The reason for this is that the sensitiveness of the device, other things being equal, depends in a measure upon the distance between the electrodes F F′, and the minimum separation can be obtained by using flat plates for the electrode F′. As will be obvious, the electrode F′ may consist of one flat plate.

The evacuated vessel D may be provided with a screw-socket 5 after the manner of ordinary incandescent lamps, and one end of the filament F may be conductively connected thereto while the other end may be insulated therefrom and conductively connected to the contact-piece 4 in the base of the socket. In such case the terminals of the heating battery B′ are connected respectively to the socket at *b* and to the contact-piece 4.

The terminals of the local circuit, which includes the battery B and signal-indicating device, such as the telephone T, are connected respectively to the electrodes F and F′ at *a* and *b*. Means may be included in or associated with the local circuit for varying the potential developed by the local circuit B between the points *a* and *b*. For this purpose the number of cells which make up the battery B may be varied, or the adjustable resistance R, which, with the battery, constitutes a potentiometer, may be used.

The oscillation-detector, as above described, may be associated with the receiving system in a variety of ways now well known in the art by connecting the electrode F to one of the terminals of the source of oscillations and the electrode F′ to the other terminal thereof. In the present instance the antenna A is connected to the electrode F′ by a leading-in wire which is connected to the base 2 and which is sealed in the vessel D at *a*, and the earth-connector is connected to the electrode F through the socket 5 and the conductor *b c*.

It is preferable that the positive pole of the battery B should be connected to the electrode F′, and better results are obtained if the negative pole of the battery B be connected to that end of the filament F to which the positive pole of the battery B′ is connected, (shown in Figs. 1, 3, and 4 as that end of said filament which is connected to the screw-socket.)

By regulating and adjusting the amount of heating-current flowing in the circuit of the battery B′, the sensitiveness of my detector may be varied, so that the response of the detector *per se* will be a function of the frequency of the electrical oscillations operating upon the same, and said detector itself, as distinguished from the circuit in which it is included, will be selectively responsive to oscillations having a given electrical frequency. For regulating and adjusting the heating-current flowing through the filament F, I may employ the rheostat R′ or any other means suitable for the purpose.

For tuning the oscillation-detector to oscillations of given electrical frequency, the amplitude of the heating-current must be determined empirically, as by adjusting the rheostat R′, because a number of factors such, for example, the separation of the electrodes F F′ and the difference of potential developed by battery B across the points *a b*, are involved.

By regulating and adjusting the potential impressed by the battery B across the electrodes F F′, the sensitiveness of the detector may be varied so that the response of the detector *per se*, other things being equal, will be a function not only of the electrical frequency or wave length of the oscillations operating upon the detector, but also of the spark frequency which, *caeteris paribus*, is a measure of the total energy received, and the detector itself, as distinguished from a circuit tuned electrically to electrical or to spark frequency and from a mechanism tuned mechanically or acoustically to spark frequency, will be selectively responsive to oscillations having a given electrical frequency, and also to oscillations having a given spark frequency irrespective of their electrical frequency or wave length. Thus, with a given separation of the electrodes F F′ and a given amplitude of heating-current flowing through the filament F, I have been able by merely varying the potential of the battery B to attune the oscillation-detector to the oscillations developed in the receiving system by one of several transmitting systems and to receive the energy thereof to the exclusion of the energies of the oscillations developed therein by the other of said transmitting systems, even when the several sets of oscillations had the same electrical frequency and wave length, but differed in spark frequency or in average energy conveyed per unit of time. Here also the adjustment of the potential impressed by the battery B upon the electrodes F F′ must be determined empirically.

By virtue of the selective properties of my detector, as above set forth, I am enabled to effect by the detector itself a method of double-tuning which affords the greatest security from waves the energy of which is not intended to affect the detector as well as from atmospheric or "static" electricity and other disturbing electrical forces.

As above mentioned, the sensitiveness of my oscillation detector, which in common with others of my invention employing a conducting gaseous medium as the sensitive element I call the "audion," is a function of the separation of the electrodes or of the length of the sensitive conducting gaseous medium; but I find that here again the frequency is a determining factor, so that by varying the separation of the electrodes I can make the response of the audion a function of the frequency. In other words, by suitably varying the length of the interelectrode medium, other adjustments, such as those of the batteries B B′, remaining unchanged, I am enabled to make the audion *per se* selectively responsive to oscillations of a given frequency independently of the usual tuned or resonant circuit heretofore employed in wireless telegraphy as a current or oscillation selector.

A convenient means of varying the distance between the electrodes F F′ is to hinge the wings which constitute the electrode F′ to the base 2 as by the hinges 1 1. By approaching the magnets 6 6 to the inverted tube, as shown in Fig. 2, the wings, which may be made wholly or partly of iron, will open outwardly away from the filament and thereby increase the path of the conducting ions in the interelectrode medium.

When the audion is to be attuned to oscillations of a given frequency by varying the separation of the electrodes, the adjustment produced by the magnets 6 6 must be empirically determined, just as the adjustments of the batteries B B′, above referred to are purely empirical.

It will be understood that each of the three methods above set forth for varying the response of the audion in accordance with the electrical frequency and the spark frequency of the oscillations to be detected may be separately employed and also that any two or all three of said methods may be used conjointly. For example, by appropriately varying the separation of the electrodes F F′ and the amplitude of the heating-current from the battery B′, the audion may be made selectively responsive to waves of a given electrical frequency, and then by the regulation and adjustment of the potential impressed upon the audion by the battery B, the audion may be made to select a particular one of a number of sets of waves all having the said electrical frequency and wave length, but each set having a spark frequency different from that of any other set.

The oscillation-detectors shown in Figs. 3 and 4 are identical in construction with those above described in connection with Figs. 1 and 2, and differ therefrom merely in the manner in which they are associated with the source of oscillations to be detected.

In Fig. 3, 7 represents a metallic member brought into proximity with the vessel D and shown in the present instance as a cylinder surrounding said vessel. In this case one terminal of the oscillation source which in the present instance is shown as a circuit including the secondary of the transformer M, is conductively connected to the cylinder 7 at the point *d*, while the other terminal may be connected to either one of the electrodes F or F′ and in the present instance is shown as connected to the electrode F through the socket 5 and conductor *b c*. In this case the oscillating electric field developed by the electrical oscillations in the secondary circuit, which includes the secondary winding I_2, operates to alter the conducting properties of the sensitive conducting gaseous medium in the vessel D and thereby to vary the current flowing in the local circuit which includes the telephone T, just as in the case of the system shown in Fig. 1 in which the terminals of the oscillation source are connected directly to the interelectrode medium.

The arrangement shown in Fig. 3 affords a fourth method of rendering the audion selectively responsive, for in addition to the three methods above set forth in connection with Figs. 1 and 2 I find that, other things being equal, the response of the audion to oscillations of a given frequency is a function of the area of the surface of the number 7 and of the separation thereof from the elements within the vessel D.

If the form shown in Fig. 3 be employed, the cylinder 7 may be moved with respect to the axis of the vessel D until, *cœteris paribus*, the response of the audion is a maximum for oscillations of a given frequency. It will be understood of course that the separation of the electrodes F, F′, and the values of the resistances R, R′, of the audion shown in Fig. 3 may all be varied in the manner above explained in connection with Figs. 1 and 2.

When the connections shown in Fig. 3 are used I find that the quality of the sound produced in the telephone T is quite different from that produced therein when the connections shown in Fig. 1 are used, although the sounds may be, and under the same conditions are, of equal intensity. When the connections shown in Fig. 1 are employed, the sounds produced by the telephone are sharp and crackling, as is the case where various other forms of oscillation-detector are employed; but when the connections shown in Fig. 3 are used, the sounds produced by the telephone, under the same conditions as before, are muffled or drummy. This latter sound is distinctive and is not produced by the use of any other form of oscillation-detector so far as I am aware. The advantage of obtaining the latter sound in the telephone is that it may readily be distinguished from the sounds produced therein by atmospheric electricity, whereas the sharp crackling sounds produced in the telephone by the signal-waves when other types of oscillation-detector are used very nearly imitate the sounds produced therein by static disturbances or atmospheric electricity.

In the arrangement shown in Fig. 4 the audion is energized by the oscillating magnetic field developed by the passage of the oscillations to be detected through the coil L which surrounds the sensitive conducting gaseous medium and which in the present instance is wound around the outside of the tube. This coil preferably is made adjustable, as by the contacts *f* and *g*, and the antenna A may include an inductance L′ having an adjusting-contact *e*. It will be understood that the adjustments of the separation of the electrodes F, F′, of the amplitude of the heating-current and of the value of the potential impressed between the points *a* and *b*, as set forth above in connection with Fig. 1, may also be employed to render the audion shown in Fig. 4 selectively responsive. I have ascertained also that the variation of the magnetic field created by the passage of oscillations through the coil L varies the response of the audion, other things being the same, and furthermore that this variation also is a function of frequency. In other words, having adjusted the audion to be most responsive to oscillations of given frequency in the manner above described in connection with Fig. 1, there may be found empirically a certain position for the contacts *f* or *g*, at which for oscillations of a said frequency the response of the detector is a maximum.

The syntonizing-inductance L′, or other electrical tuning device, may be employed in connection with any of the several embodiments of my present invention so as to combine the selectivity of the antenna or tuned receiving-circuit with the selective properties of the oscillation-detector itself, and in such cases I have found the selectivity of a receiving system so constructed to be very high indeed.

It will be understood that in all cases, if desired, the vessel D may include the vapor of a halogen salt or other substance the vapor of which is conducting or a gas whose conductivity is greater than that of air under an attenuated pressure.

I claim—

1. An electrical-oscillation-selecting device comprising a vessel, a filament sealed in said vessel, a source of electric current connected in series with said filament, means for varying the amplitude of said current, whereby said device is rendered selective of electrical oscillations having a given electrical frequency, a member of conducting material inclosed within said vessel and a circuit connecting said member with said filament.

2. An electrical-oscillation-selecting device comprising a vessel, a filament sealed in said vessel, a source of electric current connected in series with said filament, a member of conducting material inclosed within said vessel, a circuit connecting said member with said filament, a source of electromotive force associated with said circuit and means for varying said electromotive force, whereby said device is rendered selective of electrical oscillations having a given spark frequency.

3. An electrical-oscillation-selecting device comprising a vessel, a filament sealed in said vessel, a source of electric current connected in series with said filament, means for varying the amplitude of said current, whereby said device is rendered selective of electrical oscillations having a given electrical frequency, a member of conducting material inclosed within said vessel, a circuit connecting said member and said filament, a source of electromotive force associated with said circuit and means for varying said electromotive force, whereby said device is rendered selective of electrical oscillations having a given spark frequency.

4. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium maintained in a condition of molecular activity, two electrodes inclosed within said vessel, and means for varying the separation of said electrodes.

5. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium maintained in a condition of molecular activity, two electrodes inclosed within said vessel, and means outside said vessel for varying the separation of said electrodes.

6. An electrical-oscillation-selecting device comprising a vessel, a filament sealed in said vessel, a source of electric current connected in series with said filament, a member of conducting material inclosed within said vessel, a circuit connecting said filament and said member and means for varying the separation of said filament and said member.

7 An electrical-oscillation-selecting device comprising a vessel, a filament sealed in

said vessel, a source of electric current connected in series with said filament, and means for varying the amplitude of said current, whereby said device is rendered selective of electrical oscillations having a given electrical frequency.

8. An electrical - oscillation - selecting device comprising a vessel, a filament sealed in said vessel, a source of electric current connected in series with said filament, a member of conducting material inclosed within said vessel, a circuit connecting said filament with said member, a source of electromotive force associated with said circuit, means for varying said electromotive force and means for varying the separation of said filament and said member.

9. An electrical - oscillation - selecting device comprising a vessel, a filament sealed in said vessel, a source of electric current connected in series with said filament, means for varying the amplitude of said current, whereby said device is rendered selective of electrical oscillations having a given electrical frequency, a conductor inclosed within said vessel, a circuit connecting said conductor and filament, a source of electromotive force associated with said circuit and means for varying said electromotive force, whereby said device is rendered selective of electrical oscillations having a given spark frequency.

10. An oscillation-detector and means whereby said detector *per se* is rendered selective of electrical oscillations having a given spark frequency.

11. An oscillation-detector, means whereby said detector *per se* is rendered selective of electrical oscillations having a given electrical frequency and means whereby said detector *per se* is rendered selective to electrical oscillations having a given spark frequency.

12. An electrical-oscillation-selecting device comprising a vessel containing a sensitive conducting gaseous medium, two electrodes within said vessel, a local circuit connecting said electrodes, a receiving-circuit having one terminal connected with one of said electrodes, a conducting member outside said vessel and movable with respect thereto, and an electrical connection from the other terminal of said receiving-circuit to said conducting member.

13. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium maintained in a condition of molecular activity, two electrodes inclosed within said vessel, means for impressing an electrical potential upon said electrodes, and means for varying said potential.

14. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium, an electrode within said vessel, means for heating said electrode, means for regulating the temperature thereof, a second electrode inclosed within said vessel and a circuit connecting said electrodes.

15. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium, an electrode within said vessel, means for heating said electrode, means for regulating the temperature thereof, a second electrode inclosed within said vessel, means for impressing an electrical potential upon said electrodes and means for varying said potential.

16. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium maintained in a condition of molecular activity, two electrodes inclosed within said vessel, a local circuit connecting said electrodes and means for varying the separation of said electrodes.

17. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium, an electrode within said vessel, means for heating said electrode, means for varying the temperature thereof, a second electrode inclosed within said vessel and means for varying the separation of said electrodes.

18. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium, an electrode within said vessel, means for heating said electrode, means for varying the temperature thereof, a second electrode inclosed within said vessel, a circuit connecting said electrodes, an adjustable source of electromotive force associated with said electrodes, and means for varying the separation of said electrodes.

19. An electrical-oscillation detector comprising a vessel inclosing a gaseous medium, means for maintaining said gaseous medium in a condition of molecular activity, a member in proximity to said vessel, and an oscillation-circuit electrically connected to said member and to said gaseous medium.

20. An electrical-oscillation-selecting device comprising a vessel inclosing a gaseous medium, means for heating said medium, and means for varying the temperature thereof, whereby said device is rendered selective of electrical oscillations having a given electrical frequency.

21. An oscillation-detector comprising two conductively-connected flat plates of conducting material inclosed within an evacuated vessel, an electrode sealed within said vessel and located between said plates, and means for heating said electrode.

22. An oscillation-detector comprising two conductively-connected flat plates of conducting material inclosed within an evacuated vessel, a metallic filament sealed within said vessel and located between said plates, and means for heating said filament.

23. An oscillation-detector comprising two conductively-connected flat plates of con-

ducting material inclosed within an evacuated vessel, a filament of tantalum sealed within said vessel and located between said plates, and means for heating said filament.

24. An oscillation-detector comprising two flat plates of conducting material inclosed within an evacuated vessel, an electrode sealed within said vessel and located between said plates, and means for heating said electrode.

25. An oscillation-detector comprising two flat plates of conducting material inclosed within an evacuated vessel, a filament sealed within said vessel and located between said plates, and means for heating said filament.

In testimony whereof I have hereunto subscribed my name this 24th day of August, 1906.

UNITED STATES PATENT OFFICE.

LEE DE FOREST, OF NEW YORK, N. Y.

DEVICE FOR AMPLIFYING FEEBLE ELECTRICAL CURRENTS.

No. 841,387. **Specification of Letters Patent.** Patented Jan. 15, 1907.

Application filed October 25, 1906. Serial No. 340,487.

To all whom it may concern:

Be it known that I, Lee de Forest, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented a new and useful Improvement in Devices for Amplifying Feeble Electrical Currents, of which the following is a specification.

My invention relates to devices for amplifying feeble electrical currents—such, for example, as telephone-currents; and its object is to produce an amplifying device of greater efficiency and simplicity than those heretofore employed.

My invention will be described with reference to the drawings accompanying and forming a part of this specification, and in which—

Figures 1, 2, 3, 4, 5, 6, and 7 represent conventionally or diagrammatically various arrangements of apparatus and circuits whereby my invention may be carried into effect.

In the figures, A represents an evacuated vessel inclosing a sensitive conducting gaseous medium maintained in a condition of molecular activity.

R is a signal-indicating device.

B B are batteries or other sources of electrical energy.

D E D', are electrodes sealed within the receptacle A.

The circuit B R D E is a local receiving-circuit. The circuit F is a line-circuit conveying the currents to be amplified to the amplifying device. The electrode E, which may be of platinum, tantalum, carbon, or other suitable material, is heated and preferably maintained incandescent by the battery B'. The electrodes D and D , which may be plates of platinum or other suitable material, are placed in close proximity to the electrode E, and when the electrode D' is employed its separation from the electrode E preferably is less than that of the electrode D therefrom.

In Fig. 1, N S represent a magnet placed adjacent to the vessel A. The currents to be amplified may be impressed upon the circuit which includes the heated electrode or filament E—as, for example, by means of the transformer M—and the magnetic field set up by these currents reacts upon the field set up by the magnet N S, thereby causing a slight variation in the separation between the electrodes D E. I have found that the slightest variation in the separation of the hot and cold electrodes produces a large and disproportionately greater variation in the flux between said electrodes, especially if the latter are close together, and such variation in flux may be made manifest by the signal-indicating device R.

In Fig. 2 the current to be amplified may be impressed upon the medium intervening between the electrodes D and E, and thereby alter, by electrostatic attraction, the separation between the electrodes. In this case D' may be a strip of platinum-foil, and the slightest approach thereof toward the filament will act to slightly cool the gaseous medium, and thereby alter the current in the local circuit, or, if D' is rigid, the increase in electrostatic attraction between D' and E will cause E to recede from D, and thereby alter the current in the local circuit.

In Fig. 3 the filament E is connected, by means of a minute platinum wire I, to the arm J which is secured to the coil *a*, placed between the poles of the magnet H and secured to the walls of the vessel A through the spiral springs *b b*. The line-current to be amplified in this case is passed through the coil *a* through the springs *b b*, and the resulting rotation of the coil varies the separation between the electrodes D E, thereby altering the current in the local circuit.

In Fig. 4 the currents to be amplified may be impressed upon the gaseous medium intervening between D' and E by means of the transformer M'. A condenser C may be included in series with the secondary of said transformer and the electrodes D' E. In this case there may or may not be a variation between the separation of the electrodes, and the currents to be amplified may vary the motions of the ions around the filament, thereby controlling to a greater degree the flux between said filament and the electrode D.

In Fig. 5 the currents to be amplified may be passed through the solenoid surrounding the magnet N S, and thereby vary the field, which by coacting with the magnetic field surrounding the electrode E determines the normal separation of the electrodes D and E. Even without creating actual movements between the electrodes D and E the varying magnetic flux produced by the line-current passing through the solenoid L will affect the motion of the ions in the gaseous medium, and thereby alter the current in the local circuit.

In Fig. 6 the electrode D may be constituted of iron or may consist of platinum plates provided with small iron armatures O O. In either case the currents to be amplified by passing through the solenoids P P, which surround the poles of the magnet N, effect the desired variation in the separation of the electrodes D and E.

In Fig. 7 the electrode D and diaphragm S may both be rigidly secured to the inside and outside, respectively, of the glass wall of the vessel A at a point where said wall has been flattened and made very thin, like the crystal of a watch. The currents to be amplified in this case by operating upon the coils P′ P′, surrounding the magnet Q, effect slight movements of the diaphragm S, and these movements are mechanically transmitted through the glass wall of the vessel A to the electrode D, thereby varying the current in the local receiving-circuit.

It will be obvious that the amplifying device, which constitutes the subject-matter of the present invention, is not limited in its use to any particular kind of electrical circuit or apparatus, but that it is capable of general application wherever an amplifying device is required. By way of example of its application to a wire telegraph or cable system I have shown the line F in Fig. 1 as including a telegraph transmitting-key T′ and source of vibratory current G. In Fig. 2 I have shown the line F as constituting the local circuit of a wireless-telegraph receiving system including the battery B″ and oscillation-detector T″, the latter being connected in series with an antenna V and the earth E′. In Fig. 4 I have shown the line F as constituting a telephone-circuit including the microphone-transmitter T‴ and battery B‴. In all instances it will be understood by those skilled in the art and without going into further detail that the signal-indicating device R, which is included in the local receiving-circuit, may be any device suitable for the purpose of reproducing the signal initiated in the line F

I do not limit myself to any of the specific embodiments of my invention herein described, inasmuch as many modifications will readily occur to those skilled in the art without departing from the principle of my invention.

I claim—

1. In a device for amplifying electrical currents, an evacuated vessel inclosing a sensitive conducting gaseous medium maintained in a condition of molecular activity, two electrodes sealed within said vessel, a local receiving-circuit associated with said electrodes, and means whereby the separation of said electrodes may be varied by the currents to be amplified.

2. In a device for amplifying electrical currents, an evacuated vessel, two electrodes sealed within said vessel, means for heating one of said electrodes, a local receiving-circuit associated with said electrodes, and means whereby the separation of said electrodes may be varied by the currents to be amplified.

3. In a device for amplifying electrical currents, an evacuated vessel, two electrodes sealed within said vessel, a circuit including a source of electric energy connected in series with one of said electrodes, a local receiving-circuit associated with said electrodes, and means whereby the separation of said electrodes may be varied by the currents to be amplified.

4. In a device for amplifying electrical currents, an evacuated vessel, three electrodes sealed within said vessel, means for heating one of said electrodes, a local receiving-circuit including two of said electrodes, and means for passing the current to be amplified between one of the electrodes which is included in the receiving-circuit and the third electrode.

5. In a device for amplifying electrical currents, an evacuated vessel inclosing a gaseous medium, means other than the received energy for maintaining said gaseous medium in a condition of molecular activity, means for impressing the currents to be amplified upon said gaseous medium, and a local receiving-circuit having its electrodes sealed within said vessel.

6. In a device for amplifying electrical currents, an evacuated vessel, a heated electrode and two non-heated electrodes sealed within said vessel, the non-heated electrodes being unequally spaced with respect to said heated electrode, a local receiving-circuit including said heated electrode and that one of the non-heated electrodes which has the greater separation from the heated electrode, and means for passing the current to be amplified between the heated electrode and the other non-heated electrode.

In testimony whereof I have hereunto subscribed my name this 17th day of October, 1906.

LEE DE FOREST.

M0DAD RADIO WEBSITE

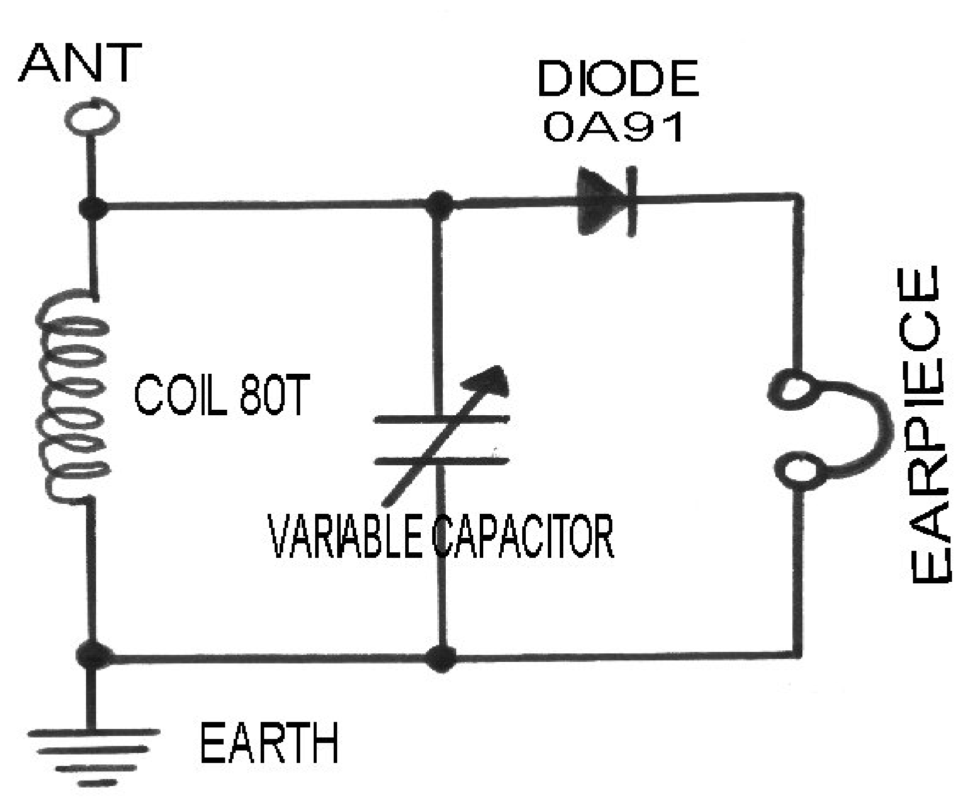
Basic Crystal Radio Set

I have been very interested in crystal radios for many years, I can remember building my first set back in my schooldays in the early 1980s. It was the first and still is the most basic of all radio receivers , If you are new to radio and have never seen one of these sets you will be very amazed at how easy it is to build a working radio needing so few components. What also may surprise a newcomer is that it does not need any battery or power to work, The only power it uses is taken from the transmitter of the station you are listening to, In other words it pulls the power from the radio wave.

The biggest craze of building and listening to crystal sets was at its peak in the 1920s. The old style sets used a real mineral crystal for the detector, The most popular being the galena and a fine bit of wire called a cats whisker which you would have to touch the crystal in the correct place to find the best reception where the radio station would come in. During world war II the underground people of Europe used crystal sets to listen to prohibited broadcast stations, Because of there simplicity to build. It is now getting harder to obtain all the original parts like the high impedance headphones, But I will show you how to build the modern day circuit using readily available parts.

My basic crystal radio project is aimed at the absolute beginner or younger generation, to try and interest them in the radio hobby as many amateur radio operators began there interest in radio with building the crystal set. The circuit can be soldered or built using chock block connectors for safety if a young person is doing this project.

CIRCUIT



ANT
DIODE
0A91
COIL 80T
VARIABLE CAPACITOR
EARPIECE
EARTH

HOW THE CIRCUIT WORKS

First of all there are many different signals from stations which will be traveling down the long wire antenna, The coil and capacitor together form a tuned circuit, And because the capacitor is a variable type you can change the resonant frequency of the tuned circuit by rotating the tuning knob on the capacitor. Only signals from stations on or near the resonant frequency can pass through the tuned circuit, The other remaining frequencies are bypassed to earth. The passed signals then go through the germanium diode (detector) which rectifies the positive half cycles changing it to DC current and then sending it to the crystal earpiece or high impedance headphones.

EARPIECE

PARTS

I personally find it a lot more fun to salvage all the parts from an old radio as it will cost you nothing, But just for this project I have listed all the parts that you will need and where to buy them from.

Variable capacitor, available from Maplin Electronics (UK) Code FT78K

Diode: Maplin Electronics 0A91, Code QH72ZP, 0A90 Code QH71N or any germanium point contact diode such as an OA70,OA71, or 1N34.

Chock block connectors Maplin Electronics (UK).

Crystal earplug, avail able from Maplin Electronics (UK) Code LB25C

26 s.w.g. Enameled copper wire.

Coil former: An empty card board toilet roll or an off cut piece of plastic waste pipe.

Base: Any piece of soft scrap wood about 4"x 5"

PVC coated wire for links.

A roll of any kind of wire PVC coated or copper wire for antenna and an earth connection.

CONSTRUCTION

Start the construction with the coil by securing the former (toilet roll, or PVC pipe) and then winding 80 turns of 26 s.w.g enameled copper wire around. When finished secure the windings with sticky tape or glue, Then scrape the wire enamel off both ends of the coil with a knife or sand paper until you can see a shiny tip. The coil can be secured to the wood base with two drawing pins.

Now the most difficult part is over , you can secure a couple of chock block connectors in front of the coil and the two behind the capacitor then wire the circuit as in the board layout, It is straight forward, but make sure you get the capacitor the correct way, the earth and antenna pins are marked e and a on the bottom, There is no connection to the pin marked o. The diode has a glass body with a band on to show the flow of the conducting current. Strip the plastic coating off the end of the crystal earpiece leads and insert them into the two rear chock blocks.

You are now ready to connect the antenna, Just string up the longest length of wire you can, run it from the set through a window and secure it to an insulated pole, tree or fence as high and as long as you possibly can to achieve the best results. If it is impossible for you to have an outdoor wire, String a wire several times around a room ceiling or an attic, It will still receive some stations but at reduced volume.

You will need an earth, run a wire from the set to a cold water pipe, connect it to the pipe or to a water tap with a crocodile clip, Or if you want a more permanent arrangement you can run a wire outside and connect it to an earth rod driven into the ground, This can be a length of copper pipe or brass rod as long and deep into the ground as you can. It is said that you must have a good earth for a crystal set to work, In practice I found it works slightly better but have also achieved good results without any earth.

OPERATING THE SET

This is the best part, When you are finished building the circuit connect the earth and antenna wires, pick up the earpiece and have a listen, You should be able to hear noise, turn the screw on the variable capacitor until you tune into a station, You should be able to hear several stations on the MW band, Depending on your location, length and how high the wire antenna is, Because this is a basic circuit you will soon notice that the set has poor selectivity, This means that sometimes you can hear two or more stations coming in together and may find it difficult to separate the one you want to listen to, That is if you can at all. If you can only receive one or two stations and the screw on the variable capacitor is fully turned, try unwinding about 4 or 5 turns off the coil. One of the most difficult requirements is having the patience, Some stations will come in loud and then may fade out altogether after a wile, If you leave it on the same frequency they can sometimes return as the propagation changes.

FAULT FINDING

If it does not work, Check your wiring with that of the board layout, And make sure all leads are not slack.

You must make sure you have a germanium point contact diode, other diodes will not work.

Make sure you have a proper crystal earpiece or high impedance headphones, Do not be confused with the standard white coloured magnetic earpiece, Unlike the standard 8 or 16 ohm earphones of today crystal earpieces are into the mega ohms, So if you used the wrong type it would be like trying to run your washing machine on a PP3 9 volt battery.

EXPERIMENTING

When I built this crystal set for the web site I hooked a wire to a radiator for an earth, strung a 60 FT length of PVC coated wire through a window down to the rear garden fence, The first station I heard was quite a surprise, Radio Korea, Other stations where Virgin Radio - 1215 KHz, Talk Sport 1071 KHz, Magic 1152 KHz, BBC Radio 5 Live 693 KHz, BBC Radio 4 - 603 KHz, So it had a good range through the medium wave broadcast band.

Do not be afraid to experiment, Due to the simplicity of the set you wont break it, You can try changing the diode around, Try other coils with different number of windings, The more turns should take you lower in frequency, and the smaller number higher, try a ferrite rod as a former or salvage a ready made coil from an old broken radio. Experiment with different lengths of antenna wire. I also find these sets work better with a higher quality air spaced variable capacitor which you can buy from a radio rally or you could try J. Birkett suppliers of electronic components who always stocks them at reasonable prices, TEL NO. +44 (0)1522 520767. The company is UK based and may not export, but I am sure that you will know of local electronics suppliers for such parts.

I hope you have enjoyed reading about the crystal set and if you have built the one from this page e mail me and let me know how it went. If this page has interested you and you would like to build more sets check out my other web pages or web links page.

Battery Free Loop FM Crystal Radio

Battery Free Loop FM Radio using an 8-mm diameter copper tube.

This FM radio runs without battery and you can listen to FM radio by just placing this close to your window.
If reception is not good, you can attach an external FM antenna (or with antenna amplifier), to the Loop at the point 1/3 of the loop close to the ground.

Parts you will need:
A Diode that works in high frequency (200Mhz or above, e.g. AA112, 1N34A, 1N48, Iss86 or Iss106.
A 0-12 pf AIR Variable capacitor - you can get a 0-22pf one, then remove all the copper plates and leave just 4.
50pf and 180pf fixed ceramic capacitor
100K 1/4W resistor
33uH Choke coil.
3.5mm mini headphone jack
A high impedance 4K Ohm earphone or a crystal earphone.
Some wires.

(57) **ABSTRACT**

A portable weapon comprises a non-lethal portion and a lethal portion. The lethal portion may comprise a rifle, and the non-lethal portion may comprise a millimeter-wave directed energy weapon. The non-lethal portion may comprise a kit to add non-lethal capability to a lethal weapon. The non-lethal portion may comprise an output antenna to generate a high-power millimeter-wave initial wavefront, a main reflector, and a sub-reflector to reflect the initial wavefront to the main reflector. The main reflector may direct the reflected wavefront in a bore-sighted direction toward a target. The wavefront directed by the main reflector may have a power density selected to deliver a non-lethal deterring effect on the target. In some embodiments, the non-lethal portion may include a replaceable energy-storage module.

WEAPON HAVING LETHAL AND NON-LETHAL DIRECTED-ENERGY PORTIONS

TECHNICAL FIELD

Embodiments of the present invention pertain to portable weapons. Some embodiments pertain to directed-energy weapons and some embodiments pertain to kits for adding non-lethal capability to lethal weapons.

BACKGROUND

There are many difficult quickly changing situations in modern urban conflicts that security personnel must deal with. In modern urban conflicts, security personnel must execute dynamically changing missions that could shift rapidly between direct action, security patrols and civil stability. Among the mix of unarmed civilians, non-lethal combatants (e.g., rock throwing) and lethal combatants, it is often not immediately clear who is an innocent bystander and who poses an immediate threat to security personnel. Options for security personnel many times progress quickly from shouting to shooting. Modern urban conflicts many times require a delicate balance between the use of non-lethal force and the use of lethal force. Non-lethal weapons, when available, are generally carried separate from lethal weapons resulting in a potentially life-threatening delay for security personnel when switching between the types of weapons. Urban riot situations, for example, can easily escalate in a moment's notice and require security personnel to switch between a non-lethal response and a lethal response.

One problem with many non-lethal weapons is that they are largely ineffective over the range that lethal weapons are effective. For example, a non-lethal kinetic weapon that sends projectiles (e.g., rubber bullets) must have a reasonable range to maintain its nonlethality, however, the weapon becomes potentially lethal at close range when powerful enough to be used for longer ranges due to the initial velocity required to project the projectile over these longer ranges.

Thus, there are general needs for a non-lethal weapon that can easily be deployed along with a lethal weapon. There are also needs for a combined lethal/non-lethal weapon that has an effective non-lethal range comparable to its lethal range. There are also needs for a combined lethal/non-lethal weapon that allows security personnel to easily and quickly switch between non-lethal and lethal capabilities.

SUMMARY

A weapon having non-lethal and lethal portions is provided. The non-lethal portion directs a high-power millimeter-wave wavefront toward a target. The non-lethal portion comprises an output antenna to direct a high-power millimeter-wave initial wavefront at a sub-reflector, and a main reflector to reflect the wavefront to the target. The high-power wavefront may produce a non-lethal deterring effect on the target. The main reflector may be bore-sighted with the lethal weapon portion of the weapon to easily allow switching between non-lethal and lethal capabilities.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a perspective view of a weapon in accordance with some embodiments of the present invention;

FIG. **2** is a functional block diagram of the non-lethal portion of the weapon of FIG. **1** in accordance with some embodiments of the present invention;

FIG. **3**A is a side view illustrating the main reflector in a fully folded-up position in accordance with some embodiments of the present invention;

FIG. **3**B is a perspective view illustrating the main reflector in a fully folded-up position in accordance with some embodiments of the present invention;

FIG. **3**C is a perspective view illustrating the main reflector in a partially folded-up position in accordance with some embodiments of the present invention;

FIG. **3**D is a perspective view illustrating wings of the main reflector folded-up in accordance with some embodiments of the present invention;

FIG. **3**E is a side view illustrating wings of the main reflector partially folded-up in accordance with some embodiments of the present invention;

FIG. **3**F is a perspective view illustrating wings of the main reflector partially folded-up in accordance with some embodiments of the present invention;

FIG. **4**A is a side view illustrating the main reflector in a fully-deployed position in accordance with some embodiments of the present invention;

FIG. **4**B is a perspective view illustrating the main reflector in a fully-deployed position in accordance with some embodiments of the present invention;

FIG. **4**C is a top view of the weapon illustrated in FIGS. **4**A and **4**B;

FIG. **5**A is a side view illustrating the operation of the non-lethal portion of the weapon in accordance with embodiments of the present invention;

FIG. **5**B is a perspective view illustrating the operation of the non-lethal portion of the weapon in accordance with embodiments of the present invention;

FIG. **6**A is a side view illustrating the removable energy-storage module in accordance with embodiments of the present invention; and

FIG. **6**B is a perspective view illustrating the removable energy-storage module in accordance with embodiments of the present invention.

DETAILED DESCRIPTION

The following description and the drawings illustrate specific embodiments of the invention sufficiently to enable those skilled in the art to practice them. Other embodiments may incorporate structural, logical, electrical, process, and other changes. Examples merely typify possible variations. Individual components and functions are optional unless explicitly required, and the sequence of operations may vary. Portions and features of some embodiments may be included in or substituted for those of others. Embodiments of the invention set forth in the claims encompass all available equivalents of those claims. Embodiments of the invention may be referred to, individually or collectively, herein by the term "invention" merely for convenience and without intending to limit the scope of this application to any single invention or inventive concept if more than one is in fact disclosed.

A weapon in accordance with some embodiments of the present invention combines lethal capability with non-lethal capability allowing a user to easily switch between lethal and non-lethal force in a moment's notice. In many urban conflict situations, this ability may help save the lives of security personnel as well as the lives of innocent non-combatants. The non-lethal portion uses directed energy which, unlike many other non-lethal weapons (e.g., rubber bullets, taser, water cannons), generally causes no residual damage to a person fired upon. Because energy is the ammunition, the logistical burdens associated with conventional non-lethal weapons are significantly reduced.

FIG. **1** is a perspective view of a weapon in accordance with some embodiments of the present invention. Weapon **100** comprises non-lethal portion and lethal portion **150**. Lethal portion **150** may be any lethal weapon including a rifle or machine gun. The non-lethal portion may comprise a directed energy weapon and may be bore-sighted or aligned with the lethal portion. In some embodiments, the non-lethal portion may be a kit allowing non-lethal capability to be added to a lethal weapon, although the scope of the invention is not limited in this respect.

Non-lethal portion of weapon **100** may comprise output antenna **102** to transmit a high-power millimeter-wave initial wavefront **103**, main reflector **106**, and sub-reflector **104** to reflect initial wavefront **103** to main reflector **106**. Main reflector **106** may direct wavefront **107** in a bore-sighted direction toward a target.

In some embodiments, non-lethal portion of weapon **100** may also comprise rangefinder **108** to determine a range to the target, focus module **110** to focus wavefront **107**, replaceable energy-storage module **112** to provide energy to the non-lethal portion, and laser designator **116** for designating the target. In some embodiments, non-lethal portion may also include trigger **118** to cause the generation of wavefront **107** and on-off switch **122**. These elements are discussed in more detail below.

In some embodiments, wavefront **107** may comprise a millimeter-wave frequency, such as a W-band frequency between 94 and 96 GHz, although the scope of the invention is not limited in this respect. In some embodiments, wavefront **107** directed by main reflector **106** may have a power density selected to deliver a non-lethal deterring effect on the target. In some embodiments, wavefront **107** comprises a frequency selected to penetrate a shallow skin-depth (i.e., of less than five millimeters). In some embodiments, a power density of wavefront **107** at the target may be calculated and selected to cause a deterring effect by inducing pain on human skin. In some embodiments, wavefront **107** may comprise W-band millimeter-wave or higher frequency radiation selected to penetrate only a shallow skin-depth allowing the energy to heat the region of the skin's pain sensors, although the scope of the invention is not limited in this respect.

In some embodiments, main reflector **106** may be a collimating reflector to generate a collimated wavefront toward the target. The collimated wavefront may be substantially uniform in amplitude and/or substantially coherent in phase in a planar cross-section of a column of energy emanating from main reflector **106**, although the scope the invention is not limited in this respect.

In some other embodiments, main reflector **106** may generate a converting wavefront which may converge at or near an intended target. In these embodiments, a convergence distance may be selected to provide a predetermined power density at or near a surface of the target. In some embodiments, main reflector **106** may generate a slightly diverging wavefront. In some embodiments, the focus of wavefront **107** (i.e., whether wavefront **107** is converging, collimated or diverging) may be at least partially controlled by focus module **110**.

In some embodiments, main reflector **106** may be aligned with sights of lethal portion **150** of weapon **100**. In some embodiments, the non-lethal portion may be a bore-sighted attachment kit to add non-lethal capability to a lethal weapon. The kit may be a "B-kit" add-on to a rifle, such as an M-16 rifle, although the scope of the invention is not limited in this respect.

FIG. **2** is a functional block diagram of the non-lethal portion of the weapon of FIG. **1** in accordance with some embodiments of the present invention. Elements illustrated in FIG. **2** having the same reference number as elements in FIG. **1** may refer to the same element. As illustrated in FIG. **2**, non-lethal portion **200** may include system controller **226** to control the operation of the various elements of non-lethal portion **200**. Rangefinder **108** may determine a distance to the target and system controller **226** may determine the proper power density of wavefront **107** at or near the target based on the distance. System controller **226** may control the RF power output of amplifier **214** accordingly. On-off switch **122** may allow power to be turned off to the active elements of the non-lethal portion.

Referring to FIGS. **1** and **2** together, in some embodiments, laser designator **116** may be used to visually designate the target. Laser designator **116** may be bore-sighted with both the lethal portion and non-lethal portion. In some embodiments, rangefinder **108** may be aligned with laser designator **116**. In some embodiments, rangefinder **108** comprises a laser-rangefinder, although the scope of the invention is not limited in this respect.

In some embodiments, laser designator **116** may generate a laser-beam in parallel to wavefront **107** and may comprise a laser-diode mounted on main reflector **106**. In some embodiments, laser designator **116** may shine through a small hole in main reflector **106**. In some alternate embodiments, a laser diode may be provided at or near output antenna **102** and a laser-beam may be reflected by optically reflective portions on reflectors **104** and **106** and may be provided parallel to wavefront **107**.

Focus module **110** may change a focus of initial wavefront **103** generated by output antenna **102** based on a distance to the target. This may allow the power-density of wavefront **107** to be adjusted based on the distance to the target. In some embodiments, focus module **110** may be moveable by a user allowing the user to select a position for a focusing element based on the distance to the target. In some embodiments, the focusing element may be manually slidable by a user.

In some embodiments, focus module **110** comprises a millimeter-wave radio-frequency (RF) lens that may be positioned by focus controller **111** based on a distance to a target. In some embodiments, focus module **110** may include one or more RF lenses that may be switched in and out of the RF path by focus controller **111** to focus wavefront **107**. In some embodiments, focus controller **111** may change the relative position of sub-reflector **104** to focus wavefront **107**. In some other embodiments, system controller **226** may change the phasing of electronic phase shifters within main reflector **106** to change the focusing and phase distribution of wavefront **107**.

In yet some other embodiments, focus module **110** may be an active-lens array in which a plurality of active array elements receive the wavefront, amplify the wavefront and retransmit the wavefront. In some embodiments, focus module **110** may provide a continually variable focusing distance, while in other embodiments; focus module **110** may provide selectable discrete focusing steps. In some embodiments, focus controller **111** and/or system controller **226** may configure main reflector **104**, sub-reflector **104** and/or focus module **110** to generate a collimated wavefront, while in other embodiments; focus controller **111** and/or system controller **226** may configure main reflector **106**, sub-reflector **104** and/or focus module **110** to generate a converting wavefront. In some other embodiments, focus controller **111** and/or system controller **226** may configure main reflector **104**, sub-reflector **104** and/or focus module **110** to generate a slightly diverging wavefront.

In some embodiments, rangefinder **108** and/or focus module **110** are optional. In these embodiments, the focus of the non-lethal portion may be set at a predetermined distance or at infinity. In these embodiments, the power output of amplifier **214** may be varied, although the power output may also be set to a predetermined level.

In some embodiments, focus controller **111** may change a focus of focus module **110** in response to changes in a distance to the target provided by rangefinder **108**. In some of these embodiments, a convergence point of wavefront **107** may be selected by system controller **226** to generate a predetermined power density at or near a target.

In some embodiments, amplifier **214** may be high-power millimeter-wave amplifier coupled to output antenna **102** to generate a high-power RF signal. In some embodiments, amplifier **214** may comprise a solid-state millimeter-wave amplifier comprising a plurality of either Silicon (Si) or Gallium-Arsenide (GaAs) semiconductor amplifier elements, although the scope of the invention is not limited in this respect. In some other embodiments, amplifier **214** comprises vacuum tube amplifier elements, although the scope of the invention is not limited in this respect. In some embodiments, additional amplifiers may not be needed when a powerful enough tube source is used for amplifier **214**.

In some embodiments, output antenna **102** comprises a horn antenna and initial wavefront **103** may be a substantially spherical wavefront. In some embodiments, initial wavefront **103** may be generated from a pulsed W-band millimeter-wave signal generated by amplifier **214**, although the scope of the invention is not limited in this respect.

Replaceable and removable energy-storage module **212** may provide electrical energy for the millimeter-wave amplifier **214** and/or other elements of the non-lethal portion. In some embodiments, energy-storage module **212** comprises power element **224** which may include, for example, either batteries or a fuel cell. In some embodiments, energy-storage module **212** may comprise a disposable battery or power pack, although the scope of the invention is not limited in this respect.

In some embodiments, weapon **100** may further comprise cooling element **222** to cool amplifier **214**. In some embodiments, cooling element **222** may be part of replaceable energy-storage module **212**, although the scope of the invention is not limited in this respect.

In some embodiments, cooling element **222** may circulate a phase-change fluid to cool amplifier **214**. In some embodiments, the phase-change fluid may comprise a refrigerant, although the scope of the invention is not limited in this respect. In some embodiments, cooling element **222** may circulate a coolant and may include a reservoir to store the fluid. In some other embodiments, cooling element **222** may comprise a semiconductor-based thermo-electric cooling (TEC) element to remove heat from amplifier **214** using electric current, although the scope of the invention is not limited in this respect.

In some embodiments, cooling element **222** may use an expanding gas to cool the amplifier **214**. In these embodiments, cooling element **222** may include a pressurized chamber to store the gas. In these embodiments, the chamber, including the gas therein, may be replaceable and may be replaced as part of energy-storage module **212**. In these embodiments, the gas may be contained in a pressurized chamber that may be replaced when energy-storage module **212** is replaced. In some embodiments, the gas may comprise carbon-dioxide (CO2), although the scope of the invention is not limited in this respect.

Although FIG. **2** illustrates replaceable module **212** as including power element **224** and cooling element **222**, the scope of the invention is not limited in this respect. In some embodiments, replaceable module may also include other elements of non-lethal portion **200**.

In some embodiments, weapon **100** may further comprise lethal-weapon trigger **120** to fire the lethal portion of the weapon and non-lethal-weapon trigger **118** to fire the non-lethal portion by generating wavefront **107**.

In accordance with some embodiments, non-lethal portion may operate as follows. Switch **122** may be turned on providing power to amplifier **214** and other elements of non-lethal portion and allowing range-finder **108** to determine a distance to a target. Laser-designator **116** may also be activated to designate the target to the user, however in some embodiments; laser-designator **116** may part of lethal portion **150** and may operate independent of the non-lethal portion. Focus module **110** may adjust the power output of amplifier **214** and/or may focus the various elements based on the target's distance. In some embodiments, the power output and focus may be adjusted based on a distance to the target to provide a predetermined power density (i.e., spot size) at the target. When trigger **118** is pulled, wavefront **107** is generated to deter the target. If use of non-lethal force is not successful, the user may easily switch to lethal force.

In some embodiments, lethal portion **150** comprises a machine gun; however, lethal portion **150** of weapon **100** may comprise almost any type of gun including hand-held guns. In some embodiments, the lethal portion may comprise a rifle or a machine gun, such as an M-16 rifle, although the scope of the invention is not limited in this respect.

In some embodiments, sub-reflector **104** may have a substantially flat millimeter-wave reflective surface. In some other embodiments, sub-reflector **104** has a millimeter-wave reflective surface comprising at least a portion of a substantially hyperboloidal, ellipsoidal or paraboloidal surface. Other specifically tailored reflective surfaces or lenses may also be used.

In some embodiments, main reflector **106** may comprise a geometrically-flat electrically-parabolic surface reflector antenna having a plurality of antenna elements to receive and retransmit an incident wavefront, although the scope of the invention is not limited in this respect. In these embodiments, the antenna elements may have circumferentially varying sizes and may be arranged around a center of the main reflector. In some embodiments, the antenna elements may have their electrical shapes optimized to generate either a collimating or converging wavefront of desired power densities. In some embodiments, the antenna elements may comprise a plurality of dual-polarized dipoles that circumferentially vary in size, although the scope of the invention is not limited in this respect. In some embodiments, the antenna elements may each provide approximately a 180 degree phase shift, although the scope of the invention is not limited in this respect. In some embodiments, the individual antenna elements may have varying sizes and shapes to receive the wavefront reflected by sub-reflector **104** and generate output wavefront **107** as either a collimated wavefront or a converting wavefront. An example of a reflector suitable for use as main reflector **106** may include the geometrically-flat electrically-parabolic surface reflector antenna disclosed in U.S. Pat. No. 4,905,014, although other reflective elements may also be suitable.

In some embodiments, main reflector **106** comprises an active reflect-array antenna comprising a plurality of active elements. Each element may have a receive antenna to receive portions of the reflected wavefront, an amplifier to amplify signals from the receive antenna, and a transmit antenna to transmit the amplified signals. In these embodiments, the plurality of active elements may generate an amplified wavefront in the direction toward the target. In these embodiments, the receive and transmit antennas may be orthogonally polarized.

In some embodiments, main reflector **106** may be coupled by a hinge to the weapon **100** to allow main reflector **106** to fold back when the non-lethal portion is not being used. In some embodiments, main reflector **106** is foldable and may fold into two or more flat sections. One of the sections may be coupled by a hinge to weapon **100**, and the two or more flat sections may fold up at least partially around the weapon.

In some other embodiments, main reflector **106** comprises a single flat panel and is detachable from weapon **100**. In these embodiments, main reflector **106** may be stored in a user's backpack, for example, although the scope of the invention is not limited in this respect. In some embodiments, main reflector **106** may be able to be snapped-on to weapon **100**.

FIGS. **3**A-**3**F illustrate embodiments of the present invention having a foldable main reflector in which main reflector **106** folds up and wraps around the body of weapon **100** when the non-lethal portion is not in use. FIG. **3**A is a side view illustrating main reflector **106** in a fully folded-up position in accordance with some embodiments of the present invention. FIG. **3**B is a perspective view illustrating main reflector **106** in a fully folded-up position in accordance with some embodiments of the present invention. FIG. **3**C is a perspective view illustrating main reflector **106** in a partially folded-up position in accordance with some embodiments of the present invention. FIG. **3**D is a perspective view illustrating wings of main reflector **106** folded-up in accordance with some embodiments of the present invention. FIG. **3**E is a side view illustrating wings of main reflector **106** partially folded-up in accordance with some embodiments of the present invention. FIG. **3**F is a perspective view illustrating wings of main reflector **106** partially folded-up in accordance with some embodiments of the present invention.

FIG. **4**A is a side view illustrating main reflector **106** in a fully-deployed position in accordance with some embodiments of the present invention. FIG. **4**B is a perspective view illustrating main reflector **106** in a fully-deployed position in accordance with some embodiments of the present invention. FIG. **4**C is a top view of the weapon illustrated in FIGS. **4**A and **4**B. In these embodiments, main reflector **106** may be coupled by a hinge to weapon **100** to allow main reflector **106** to fold back when the non-lethal portion is not being used. In these embodiments, main reflector **106** comprises a single flat panel and may be detachable from weapon **100**. In these embodiments, main reflector **106** may be stored in a user's backpack, for example, although the scope of the invention is not limited in this respect. In some embodiments, main reflector **106** may be able to be snapped-on to weapon **100**.

FIG. **5**A is a side view illustrating the operation of the non-lethal portion of the weapon in accordance with embodiments of the present invention. FIG. **5**B is a perspective view illustrating the operation of the non-lethal portion of the weapon in accordance with embodiments of the present invention. The non-lethal portion is illustrated generating wavefront **107** toward a target.

FIG. **6**A is a side view illustrating the removable energy-storage module **112** in accordance with embodiments of the present invention. FIG. **6**B is a perspective view illustrating the removable energy-storage module **112** in accordance with embodiments of the present invention.

Although non-lethal portion **200** (FIG. **2**) is illustrated as having several separate functional elements, one or more of the functional elements may be combined and may be implemented by combinations of software-configured elements, such as processing elements including digital signal processors (DSPs), and/or other hardware elements. For example, some elements, such as system controller **226** (FIG. **2**) and or focus controller **111** (FIG. **2**) may comprise one or more microprocessors, DSPs, application specific integrated circuits (ASICs), and combinations of various hardware and logic circuitry for performing at least the functions described herein. In some embodiments, the functional elements of non-lethal portion **200** (FIG. **2**) may refer to one or more processes operating on one or more processing elements.

The Abstract is provided to comply with 37 C.F.R. Section 1.72(b) requiring an abstract that will allow the reader to ascertain the nature and gist of the technical disclosure. It is submitted with the understanding that it will not be used to limit or interpret the scope or meaning of the claims.

In the foregoing detailed description, various features may be occasionally grouped together in a single embodiment for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed embodiments of the subject matter require more features than are expressly recited in each claim. Rather, as the following claims reflect, invention may lie in less than all features of a single disclosed embodiment. Thus the following claims are hereby incorporated into the detailed description, with each claim standing on its own as a separate preferred embodiment.

What is claimed is:

1. A weapon having a lethal and a non-lethal portion, the non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector;

a sub-reflector to reflect the initial wavefront to the main reflector; and

a high-power millimeter-wave amplifier coupled to the output antenna to generate a high-power RF signal,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction of the lethal portion toward a target, and

wherein the weapon is portable and both the lethal and non-lethal portions are coupled together to be co-aligned in the bore-sighted direction.

2. A weapon having a lethal and a non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector; and

a sub-reflector to reflect the initial wavefront to the main reflector,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction toward a target,

wherein the non-lethal portion further comprises a rangefinder to determine a distance to the target, and

wherein a predetermined power density of the directed wavefront at or near the target is generated based on the distance.

3. The weapon of claim **2** further comprising a laser designator to visually designate the target, and

wherein the laser designator is bore-sighted with both the lethal portion and non-lethal portion.

4. A weapon having a lethal and a non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector;

a sub-reflector to reflect the initial wavefront to the main reflector; and

further comprising a focusing element to change a focus the initial wavefront generated by the output antenna based on a distance to the target,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction toward a target.

5. The weapon of claim **4** wherein the focusing element is moveable by a user allowing the user to select a focusing position for the focusing element based on the distance to the target.

6. The weapon of claim **4** wherein the focusing element comprises a millimeter-wave radio frequency lens.

7. The weapon of claim **4** further comprising a controller to change a focus of the focusing element in response to changes in a distance to the target,

wherein the focusing element is to change a convergence point of the directed wavefront to generate a predetermined power density at or near the target.

8. A weapon having a lethal and a non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector; and

a sub-reflector to reflect the initial wavefront to the main reflector,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction toward a target, and

wherein the non-lethal portion comprises a high-power millimeter-wave amplifier coupled to the output antenna to generate a high-power RF signal.

9. The weapon of claim **8** wherein a wavefront directed by the main reflector has a power density selected to deliver a non-lethal deterring effect on the target.

10. The weapon of claim **8** wherein the wavefront comprises W-band millimeter-wave frequency radiation selected to penetrate a shallow skin-depth of human skin allowing the radiation to heat a region of the skin that includes pain sensors, and

wherein a power density at the target is selected to cause a deterring effect by inducing pain on the human skin.

11. The weapon of claim **8** wherein the main reflector is a collimating reflector to generate a collimated wavefront toward the target.

12. The weapon of claim **8** wherein the main reflector is to generate a converting wavefront to converge at or near the target, wherein a convergence distance is determined to provide a predetermined power density at or near a surface of the target.

13. The weapon of claim **8** wherein the main reflector is aligned with sights of the lethal portion of the weapon, and

wherein the non-lethal portion is a bore-sighted attachment kit to add non-lethal capability to a lethal weapon.

14. The weapon of claim **8** wherein the non-lethal portion further comprises a replaceable energy-storage module to provide electrical energy for the millimeter-wave amplifier.

15. The weapon of claim **8** further comprising a cooling element to cool the amplifier, wherein the cooling element circulates a phase-change fluid to cool the amplifier.

16. The weapon of claim **8** further comprising a cooling element to cool the amplifier, wherein the cooling element uses an expanding gas to cool the amplifier, the cooling element including a pressurized chamber to store the gas,

wherein the chamber including the gas therein is replaceable and is replaces as part of a replaceable energy-storage module.

17. The weapon of claim **8** further comprising:

a lethal-weapon trigger to fire the lethal portion; and

a non-lethal-weapon trigger to activate the non-lethal portion to generate the initial wavefront,

wherein the lethal portion comprises a machine gun.

18. The weapon of claim **8** wherein the main reflector comprises a single flat panel and is detachable from the weapon.

19. The weapon of claim **8** wherein the sub-reflector has a substantially flat millimeter-wave reflective surface.

20. The weapon of claim **8** wherein the sub-reflector has a millimeter-wave reflective surface comprising at least a portion of one of a substantially hyperboloid, ellipsoid or paraboloid surface.

21. A weapon having a lethal and a non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector; and

a sub-reflector to reflect the initial wavefront to the main reflector,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction toward a target,

wherein the main reflector is a geometrically-flat electrically-parabolic surface reflector antenna having a plurality of antenna elements to receive and retransmit an incident wavefront, the antenna elements having circumferentially varying sizes arranged circumferentially around a center of the main reflector to generate either a collimating or converging wavefront.

22. A weapon having a lethal and a non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector; and

a sub-reflector to reflect the initial wavefront to the main reflector,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction toward a target,

wherein the main reflector comprises an active reflect-array antenna comprising a plurality of active elements, each element having a receive antenna to receive portions of the reflected wavefront, an amplifier to amplify signals from the receive antenna, and a transmit antenna to transmit the amplified signals, and

wherein the plurality of active elements generate an amplified wavefront for direction toward the target.

23. A weapon having a lethal and a non-lethal portion comprising:

an output antenna to transmit a high-power millimeter-wave initial wavefront;

a main reflector; and

a sub-reflector to reflect the initial wavefront to the main reflector,

wherein the main reflector is to direct the reflected wavefront in a bore-sighted direction toward a target,

wherein the main reflector is foldable into two or more flat sections,

wherein one of the sections is hinged, and

wherein the two or more flat sections fold up at least partially around the weapon.

Howard Johnson constructing one of his magnetic motors

A candid shot taken during the filming of the upcoming William Gazecki Documentary
ENERGY FROM THE VACUUM

Johnson's Motors

Johnson [[xxvii]] has built many novel linear and rotary motors and at least one self-powering magnetic rotary device — later stolen in a mysterious break-in at his laboratory — personally tested by the present author. Johnson uses a bidirectional "two particle" theory of magnetic flux lines which can be justified by Whittaker's earlier work showing the internal bidirectional energy flows in all potentials and fields. He also utilizes controlled spin-waves and self-initiated precise exchange forces, which are known to momentarily produce bursts of very strong forcefields [[xxviii]]. His approach is to use highly nonlinear assemblies of magnets which initiate the foregoing phenomena at very precise points in the rotation cycle. In short, he seeks to produce precisely located and directed sudden magnetic forces, using self-initiated nonlinear magnetic phenomena. This is analogous to what the Wankel engine did using the Lenz law effect by sharply interrupting a weak current in a external coil. We point out that the Lenz law effect and other very abrupt field changes momentarily produce not only an amplified *Poynting* energy flow component, but also an amplified *Heaviside* energy flow component as well.

The photos below are excerpted from Howard Johnson's book "Discovering Magnetism", shortly to be
re-published by Cheniere Press

The computer plots were taken of one of Howard Johnson's magnetic gates, and clearly show the spin forces
created by the magnets, and also the "firing" of a magnet, with a burst of energy that is often several hundred
times larger than the baseline magnetic strength. Howard Johnson was working in the field that is now known
as "spintronics" long before it was "officially" recognized. There are over 200 magnetic effects, and only
around half of them are understood.

(57) **ABSTRACT**

This invention is a back EMF permanent electromagnetic motor generator and method using a regauging process for capturing available electromagnetic energy in the system. The device is comprised of a rotor with magnets of the same polarity; a timing wheel in apposition to a magnetic Hall Effect pickup switch semiconductor; and a stator comprised of two bars connected by a permanent magnet with magnetized pole pieces at one end of each bar. There are input and output coils created by wrapping each bar with a conducting material such as copper wire. Energy from the output coils is transferred to a recovery rectifier or diode. The magnets of the rotor, which is located on a shaft along with the timing wheel, are in apposition to the magnetized pole pieces of the two bars. The invention works through a process of regauging, that is, the flux fields created by the coils is collapsed because of a reversal of the magnetic field in the magnetized pole pieces thus allowing the capture of available back EMP energy. Additional available energy may be captured and used to re-energize the battery, and/or sent in another direction to be used as work. As an alternative, the available back EMF energy may be dissipated into the system.

DEVICE AND METHOD OF A BACK EMF PERMANENT ELECTROMAGNETIC MOTOR GENERATOR

BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention relates generally to the capturing of electromagnetic energy using a method and device to create back EMF (electromagnetic force) and re-phasing of the back EMF to recycle and capture the available back EMF energy. Back EMF is also referred to as regauging and may be defined as energy created by the magnetic field from coils, and only by coils, and not by magnets.

2. Background Information and Related Art

Operation of a normal magnetic motor has the rotor pole attracting the stator pole, resulting in the generation of power from the magnets to the rotor and flywheel. During this phase, energy flows from the magnetics to the rotor/flywheel and is stored in the increased rotation. A rotor pole leaving a stator pole and creating a condition of drag-back results in power having to be put back into the magnetic section by the rotor and flywheel to forcibly overcome the drag-back. In a perfect, friction-free motor, the net force field is therefore referred to as most conservative. In other words, a most conservative EMF motor has maximum efficiency. Without extra energy continually fed to the motor, no net work can be done by the magnetic field, since half the time the magnetic field adds energy to the load (the rotor and flywheel) and the other half of the time it subtracts energy back from the load (the rotor and flywheel). Therefore the total net energy output is zero in any such rotary process without additional energy input. To use a present day magnetic motor, continuous energy must be input into the motor to overcome drag-back and to power the motor and its load.

Present EMF motors and generators all use such conservative fields and therefore, have internal losses. Hence, it is necessary to continually input all of the energy that the motor outputs to the load, plus more energy to cover losses inside the motor itself. EMF motors are rated for efficiency and performance by how much energy input into the motor actually results in output energy to the load. Normally, the Coefficient of Performance (COP) rating is used as a measure of efficiency. The COP is the actual output energy going into the load and powering it, divided by the energy that must be input into the device with its load. COP is the power out into the load, divided by the power input into the motor/load combination. If there were zero internal losses in a motor, that "perfect" motor would have a coefficient of performance (COP) equal to 1.0. That is, all energy input into the motor would be output by the motor directly into the load, and none of the input energy would be lost or dissipated in the motor itself.

In magnetic motor generators presently in use, however, due to friction and design flaws, there are always internal losses and inefficiencies. Some of the energy input into the motor is dissipated in these internal losses. As a consequence, the energy that gets to the load is always less than the input energy. So a standard motor operates with a COP of less than 1.0 which is expressed as COP<1.0. An inefficient motor may have a COP=0.4 or 0.45, while a specially designed, highly efficient motor may have a COP=0.85.

The conservative field inside of a motor itself can be divided into two phases. Producing a conservative field involves net symmetry between the "power out" phase from the magnetics to the rotor/flywheel and the "power back in" phase from the rotor/flywheel back to the magnetics. That is, the two flows of energy (one from the magnetics into the rotor and flywheel, and one from the rotor and flywheel back to the magnetics) are identical in magnitude but opposite in direction. Each phase alone is said to be "asymmetrical"; that is, it either has: 1) a net energy flow out to the rotor/flywheel; or 2) a net energy flow back into the magnetics from the rotor/flywheel. In simplified terms, it is referred to as "power out" and "power back in" phases with respect to the motor magnetics. Hence, the two asymmetrical phases are: 1) the power-out phase; and 2) the "power back in" phase, with reference to the magnetics.

For the power-out phase, energy is derived from the EMF existing between the stator pole and incoming rotor pole in an attraction mode. In this phase, the rotary motion (angular momentum and kinetic energy) of the rotor and flywheel is increased. In short, power is added to the rotor/flywheel (and thus to the load) from the fields between stator pole and rotor pole (the electromagnetic aspects of the system).

For the "power back in" phase, energy must be fed back into the magnetics from the rotor and flywheel (and the load) to overcome the drag-back forces existing between stator pole and outgoing rotor pole. In this phase, energy is returned back to the internal magnetic system from the rotary motion of the rotor and flywheel (the angular momentum, which is the rotational energy×time). As is well known in physics, a rotor/flywheel's angular momentum provides a convenient way to store energy with the spinning rotor/flywheel mass acting as an energy reservoir.

All present day conventional magnetic motors use various methods for overcoming and partially reversing back EMF. Back EMF is the return pulse from the coil out of phase and is also referred to as regauging. The back EMF is shorted out and the rotor is attracted back in, therefore eliminating back drag. This can be accomplished by pouring in more energy, which overpowers the back EMF, thereby producing a forward EMP in that region. The energy required for this method must be furnished by the operator.

The motor of the present invention uses only a small amount of energy to "trigger" a much larger input of available energy by supplying back EMF, thus increasing the potential energy of the system. It then utilizes this excess potential energy to reduce or reverse back EMF, thereby increasing the efficiency of the motor and, therefore, the COP.

If the energy in phase 1 (the power-out phase) is increased by additional available energy in the electromagnetics themselves, then the energy in phase 1 can be made greater than the energy in phase 2 (the power-back-in phase) without the operator furnishing the energy utilized. This produces a non-conservative net field. Net power can then be taken from the rotating stator and flywheel, because the available energy added into the stator and flywheel by the additional effects, is transformed by the rotor/flywheel into excess angular momentum and stored as such. Angular momentum is conserved at all times; but now some of the angular momentum added to the flywheel is evoked by additional effects in the electromagnetics rather than being furnished by the operator.

Electrodynamicists assume that the potential available energy of any system can be changed at will and without cost. This is back EMF and is well-known in physics. It is also routinely employed by electrodynamicists in the theoretical aspects. But to simplify the mathematics, electrodynamicists will create a back EMF twice simultaneously, each back EMF carefully selected just so that the two available forces that are produced are equal and opposite and cancel each other "symmetrically". This is referred to as "symmetrical back EMF". A symmetrical back EMF system cannot produce a COP>1.0.

On the other hand, the motor of the present invention deliberately creates a back EMF itself and its potential energy only once at a time, thereby retaining each extra force for a period of time and applying it to increase the angular momentum and kinetic energy of the rotor and flywheel. Specifically, this back EMF energy with its net force is deliberately applied in the motor of the present invention to overcome and even reverse the conventional drag-back (the back EMF). Hence less energy must be taken from the rotor and flywheel to overcome the reduced back EMF, and in the ideal case none is required since the back EMF has been overpowered and converted to forward EMF by the back EMF energy and force. In the motor of the present invention, the conventional back-drag section of the magnetics becomes a forward-EMF section and now adds energy to the rotor/flywheel instead of subtracting it. The important feature is that the operator only pays for the small amount of energy necessary to trigger the back EMF, and does not have to furnish the much larger back EMF energy itself.

When the desired energy in phase 1 (the power out phase) is thus made greater than the undesired "drag-back" energy in phase 2, then part of the output power normally dragged back from the rotor and flywheel by the fields in phase 2 is not required. Hence, additional power compared to the system (without the special back EMF mechanisms) is available from the rotor/flywheel. The rotor maintains additional angular momentum and kinetic energy, compared to a system which does not produce back EMF itself. Consequently, the excess angular momentum retained by the rotor and flywheel can be utilized as additional shaft power to power an external load connected to the shaft.

A standard magnetic motor operates as the result of the motor being furnished with external energy input into the system by the operator to reduce phase 2 (power back into the magnetics from the rotor/flywheel) by any of several methods and mechanisms. The primary purpose of this external energy input into the system is to overcome the back EMF and also provide for the inevitable energy losses in the system. There is no input of energy separate from the operator input. Therefore, the COP of any standard magnetic motor is COP less than 1.0. The efficiency of a standard magnetic motor varies from less than 50% to a maximum of about 85%, and so has a COP<1.0. When nothing is done in the motor that will produce a reduction of the back EMF without the operator inputing all the energy for it, then for even a frictionless, ideal permanent magnet motor, the COP can never exceed 1.0.

Until the introduction of the motor of the present invention, it has been standard universal practice that the operator must furnish all energy used to reduce the back EMF, provide for the internal losses, and power the load. It is therefore a common belief by the scientific community that an ideal (loss-less) permanent magnet motor cannot exceed COP=1.0. And that is true, so long as the operator himself must furnish all the energy. Further, since real permanent magnetic motors have real internal losses, some of the input energy is always lost in the motor itself, and that lost energy is not available for powering the rotor/flywheel and load. Hence a real permanent magnetic motor of the conventional kind will always have a COP<1.0.

The common assumption that the COP of a motor is limited to less than 1.0 is not necessarily true, and that COP>1.0 is permitted without violating the laws of nature, laws of physics, or laws of thermodynamics. However, it can immediately be seen that any permanent magnet motor exhibiting a COP>1.0 must have some available energy input returning in the form of back EMF.

A problem relates to how back EMF energy can be obtained from a circuit's external environment for the specific task of reducing the back-drag EMF without the operator having to supply any input of that excess energy. In short, the ultimate challenge is to find a way to cause the system to: 1) become an open dissipative system, that is, a system receiving available excess energy from its environment, in other words, from an external source; and 2) use that available excess energy to reduce the drag-back EMF between stator and rotor poles as the rotor pole is leaving the stator pole. If this objective can be accomplished, the system will be removed from thermodynamic equilibrium. Instead, it will be converted to a system out-of-thermodynamic equilibrium. Such a system is not required to obey classical equilibrium thermodynamics.

Instead, an out-of-equilibrium thermodynamic system must obey the thermodynamics of open systems far from the established and well-known parameters of thermodynamic equilibrium. As is well known in the physics of thermodynamics, such open systems can permissibly: 1) self-order; 2) self-oscillate; 3) output more back EMF energy than energy input by the operator (the available excess back EMF energy is received from an external source and some energy is input by the operator as well); 4) power itself as well as its loads and losses simultaneously (in that case, all the energy is received from the available external source and there is no input energy from the operator); and 5) exhibit negentropy, that is, produce an increase of energy that is available in the system, and that is independent of the energy put into the system by the operator. As a definition, entropy roughly corresponds to the energy of a system that has become unavailable for use. Negentropy corresponds to additional energy of a system that has become available for use.

In the back EMF permanent magnet electromagnetic motor generator of the present invention, several known processes and methods are utilized which allow the invention to operate periodically as an open dissipative system (receiving available excess energy from back EMF) far from thermodynamic equilibrium, whereby it produces and receives its excess energy from a known external source.

A method is utilized to temporarily produce a much larger source of available external energy around an energized coil. Then the unique design features of this new motor provides a method and mechanism that can immediately produce a second increase in that energy, concurrently as the energy flow is reversed. Therefore, the motor is capable of producing two asymmetrical back EMFs, one after the other, of the energy within a single coil, which dramatically increases the energy available and causes that available excess energy to then enter the circuit impulsively, being collected and utilized.

The present motor utilizes this available excess back EMF energy to overcome and even reverse the back-drag EMF between stator pole and rotor pole, while furnishing only a small trigger pulse of energy necessary to control and activate the direction of the back EMF energy flow.

By using a number of such dual asymmetrical self back EMFs for every revolution of the rotor, the rotor and flywheel collectively focus all the excess impulsive inputs into increased angular momentum (expressed as energy× time), shaft torque, and shaft power.

Further, some of the excess energy deliberately generated in the coil by the utilization of the dual process manifests in the form of excess electrical energy in the circuit and is utilized to power electrical loads, e.g., a lamp, fan, motor, or other electrical devices. The remainder of the excess energy generated in the coil can be used to power the rotor and flywheel, with the rotor/flywheel also furnishing shaft horsepower for powering mechanical loads.

This new and unique motor utilizes a means to furnish the relatively small amount of energy to initiate the impulsive asymmetrical self back EMF actions. Then part of the available excess electrical power drawn off from the back EMFs is utilized to recharge the battery with dramatically increased over voltage pulses.

The unique design features of this motor utilize both north and south magnetic poles of each rotor and stator magnet. Therefore, the number of impulsive self back EMFs in a single rotation of the rotor is doubled. Advanced designs increase the number of self back EMFs in a single rotor rotation with the result that there is an increase in the number of impulses per rotation which increase the power output of this new motor.

The sharp voltage pulse produced in the coil of this new motor by the rapidly collapsing field in the back EMF coil is connected to a battery in charge mode and to an external electrical load. The net result is that the coil asymmetrically creates back EMF itself in a manner adding available energy and impulse to the circuit. The excess available energy collected in the coil is used to reverse the back-EMF phase of the stator-rotor fields to a forward EMF condition, impulsively adding acceleration and angular momentum to the rotor and flywheel. At the same time, a part of the excess energy collected in the coil is used to power electrical loads such as charging a battery and operating a lamp or such other device.

It is well known in the art that changing the voltage alone creates a back EMF and requires no work. This is because to change the potential energy does not require changing the form of that potential energy, but only its magnitude. Work is rigorously the changing of the form of energy. Therefore, as long as the form of the potential energy is not changed, the magnitude can be changed without having to perform work in the process. The motor of the present invention takes advantage of this permissible operation to create back EMF asymmetrically, and thereby change its own usable available potential energy.

In an electric power system, the potential (voltage) is changed by inputing energy to do work on the internal charges of the generator or battery. This potential energy is expended within the generator (or battery) to force the internal charges apart, forming a source dipole. Then the external closed circuit system connected to that source dipole ineptly pumps the spent electrons in the ground line back through the back EMP of the source dipole, thereby scattering the charges and killing the dipole. This shuts off the energy flow from the source dipole to the external circuit. As a consequence of that conventional method, it is a requirement to input and replace additional energy to again restore the dipole. The circuits currently utilized in most electrical generators have been designed to keep on destroying the energy flow by continually scattering all of the dipole charges and terminating the dipole. Therefore, it is necessary to keep on inputing energy to the generator to keep restoring its source dipole.

An investigation of particle physics is required to see what furnishes the energy to the external circuit. Since neither a battery nor a generator furnishes energy to the external circuit, but only furnishes energy to form the source dipole, a better understanding of the electric power principle is required to fully understand how this new motor functions. A typical battery uses its stored chemical energy to form the source dipole. A generator utilizes its input shaft energy to rotate, forming an internal magnetic field in which the positive charges are forced to move in one direction and the negative charges in the reverse direction, thereby forming the source dipole. In other words, the energy input into the generator does nothing except form the source dipole. None of the input energy goes to the external circuit. If increased current is drawn into the external load, there also is increased spent electron flow being rammed back through the source dipole, destroying it faster. Therefore, dipole-restoring-energy has to be inputed faster. The chemical energy of the battery also is expended only to separate its internal charges and form its source dipole. Again, if increased current and power is drawn into the external load, there is increased spent electron flow being rammed back through the source dipole, destroying it faster. This results in a depletion of the battery's stored energy faster, by forcing it to have to keep restoring the dipole faster.

Once the generator or battery source dipole is formed (the dipole is attached also to the external circuit), it is well known in particle physics that the dipole (as is any charge) is a broken symmetry in the vacuum energy flux. By definition, this means that the source dipole extracts and orders part of that energy received from its vacuum interaction, and pours that energy out as the energy flowing through all space surrounding the external conductors in the attached circuit. Most of this enormous energy flow surging through space surrounding the external circuit does not strike the circuit at all, and does not get intercepted or utilized. Neither is it diverged into the circuit to power the electrons, but passes on out into space and is just "wasted". Only a small "sheath" of the energy flow along the surface of the conductors strikes the surface charges in those conductors and is thereby diverged into the circuit to power the electrons. Standard texts show the huge available but wasted energy flow component, but only calculate the small portion of the energy flow that strikes the circuit, is caught by it, and is utilized to power it.

In a typical circuit, the huge available but "wasted" component of the energy flow is about 10^{13} times as large as is the small component intercepted by the surface charges and diverged into the circuit to power it. Hence, around every circuit and circuit element such as a coil, there exists a huge non-intercepted, non-diverged energy flow that is far greater than the small energy flow being diverted and used by the circuit or element.

Thus there exists an enormous untapped energy flow immediately surrounding every EMF power circuit, from which available excess energy can be intercepted and collected by the circuit, if respective non-linear actions are initiated that sharply affect and increase the reaction cross section of the circuit (i.e., its ability to intercept this available but usually wasted energy flow).

The method in which the motor of the present invention alters the reaction cross section of the coils in the circuit, is by a novel use, which momentarily changes the reaction cross section of the coil in which it is invoked. Thus, by this new motor using only a small amount of current in the form of a triggering pulse, it is able to evoke and control the immediate change of the coil's reaction cross section to this normally wasted energy flow component. As a result, the motor captures and directs some of this usually wasted environmental energy, collecting the available excess energy in the coil and then releasing it for use in the motor. By timing and switching, the innovative gate design in this new motor directs the available excess energy so that it overcomes and reverses the return EMF of the rotor-stator pole combination during what would normally be the back EMF and demonstrates the creation of the second back EMF of the system. Now instead of an "equal retardation" force being produced in the back EMF region, a forward EMF is produced that is additive to the rotor/flywheel energy and not subtractive. In short, it further accelerates the rotor/flywheel.

This results in a non-conservative magnetic field along the rotor's path. The line integral of the field around that path (i.e., the net work on the rotor/flywheel to increase its energy and angular momentum) is not zero but a significant amount. Hence, the creation of an asymmetrical back EMF impulse magnetic motor: 1) takes its available excess energy from a known external source, the huge usually non-intercepted portion of the energy flow around the coil; 2) further increases the source dipolarity by this back EMF energy; and 3) produces available excess energy flow directly from the source dipole's increased broken symmetry in its fierce energy exchange with the local vacuum.

No laws of physics or thermodynamics are violated in the method and device of the present invention, and conservation of energy rigorously applies at all times. Nonetheless, by operating as an open dissipative system not in thermodynamic equilibrium with the active vacuum, the system can permissibly receive available excess energy from a known environmental source and output more energy to a load than must be input by the operator alone. As an open system not in thermodynamic equilibrium, this new and unique motor can tap in on back EMF to energize itself, loads and losses simultaneously, fully complying with known laws of physics and thermodynamics.

A search of prior art failed to reveal any devices that recycle available energy from back EMF of a permanent electromagnetic motor generator as described in the present invention. However, the following prior art patents were reviewed:

SUMMARY OF THE INVENTION

The device and method of the present invention is a new permanent electromagnetic motor generator that recycles back EMF energy (regauging) thus allowing the motor to produce an energy level of COP=0.98, more or less, depending upon configuration, circuitry, switching elements and the number and size of stators, rotors and coils that comprise the motor. The rotor is fixed between two pole pieces of the stator. The motor generator is initially energized from a small starter battery means, analogous to a spark plug, that sends a small amount of energy to the motor, thus stimulating a rotating motion from the rotor. As the rotor rotates, energy is captured from the surrounding electromagnetic field containing an asymmetrical pulse wave of back EMF. The energy produced and captured can be directed in one of several directions, including returning energy to the initial starter battery, rotating a shaft for work and/or sending a current to energize a fan, light bulb or other such device.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a top perspective view of a back EMF permanent electromagnetic motor generator with a single stator and a single rotor.

FIG. **1***a* is a side perspective view of a timing wheel and magnetic Hall Effect uptake switch of the back EMF motor generator.

FIG. **1***b* is a side perspective view of the rotor of the back EMF motor generator.

FIG. **2** is a schematic drawing incorporating circuitry for the back EMF motor generator.

FIG. **3** is a box diagram showing the relationships of the back EMF motor generator circuitry.

DETAILED DESCRIPTION OF THE INVENTION

The present invention is a device and method for creating a back EMF permanent electromagnetic motor generator. As described in the Background Information, this new motor generator conforms to all applicable electrodynamic laws of physics and is in harmony with the law of the conservation of energy, the laws of electromagnetism and other related natural laws.

The back EMF permanent electromagnetic motor generator is comprised of combination of electrical, material and magnetic elements to capture available electromagnetic energy (back EMF) in a recovery rectifier or single diode from output coils. The capturing of back EMF energy is also known as regauging in the art. As an arbitrary starting point in describing this invention, an input battery, as a means of energy, sends power through a power on-off switch and then to a means for timing such as a magnetic timing switch (Hall Effect magnetic pickup switch, a semiconductor) which interfaces with or is in apposition to a magnet on a timing wheel. The timing wheel may contain any number of magnets of one or more, with the South polarity facing outward and in apposition with the Hall Effect pickup switch. The timing wheel is mounted at the end of a shaft that also runs through the center midline of a rotor containing any number of magnets of two or more. The rotor magnets are arranged in a manner wherein they have the same polarity and are equidistant from each other. The shaft has the timing wheel mounted at one end, the rotor, and then a means for work, such as a power take off at the opposite end. However, there are other embodiments in which the position of the rotor, timing wheel and power take-off have other arrangements. The rotor is stabilized to a platform or housing means and is fixed in a stationary position within a stator.

The stator is comprised of a permanent magnet connected to a means for conducting electromagnetic energy such as two parallel bars, each bar having a magnetized pole piece at one end of each bar. The conduction material of the bar may be ferrous, powdered iron, silicon steel, stainless magnetic steel, laminations of conductive material or any other magnetic conductive material. Each bar is wrapped in a conducting means to form an input coil. The means for conducting may be copper, aluminum or any other conductive material suitable for making a coil. The primary or input coil is connected to the switching circuit. A second conductive wrapping on top of the input coil becomes a secondary or output coil. The secondary or output coil is connected to the recovery circuit. The rotor is symmetrically located between the pole pieces of the bars of the stator and contains a series of magnets all having the same polarity, North or South, with each magnet in the rotor being in apposition to the pole piece as the rotor is in rotation around the shaft.

When the rotor is energized from the battery of the switching circuit, there is an initial magnetic field that is instantly overcome as the magnetized pole pieces are in apposition with the rotor magnets. As the rotor begins to move, increasing electromagnetic energy is produced as a result of flux gaiting from the apposed magnets of the rotor and pole pieces. The coils surrounding the bars "buck" the permanent magnet connecting the bars. This is known in the art as the "buck boosting" principle. When the permanent magnet is bucked by the coils, it reverses the polarity of the pole pieces which are apposed to the rotor magnets causing the rotor to increase its rotation or spin. The energy available from the fields that are collapsing in the primary and secondary coils, which creates the back EMF within the system, is now in non-equilibrium. Through circuitry and a switching means, energy can be put back into the system. Available energy captured from the back EMF, may be applied in different directions, including re-energizing the input battery, storage in a capacitor, conversion by a recovery rectifier to be stored in the input battery, a capacitor or a secondary or recovery battery. Recovery rectifiers convert AC to DC. Available energy may be used to energize an electric bulb, fan or any other uses.

The shaft in the midline of the rotor can transfer energy in the form of work through a power take-off. The power take-off may be connected to any number of secondary shafts, wheels, gears and belts to increase or reduce torque.

This is a description of the basic invention, however, there are an innumerable number of combinations and embodiments of stators, rotors, Hall Effect magnetic pickup switches, coils, recovery rectifiers and electronic connecting modes that may be combined on a single shaft or several shafts connected in various combinations and sequences, and of various sizes. There may be any number of stators to one rotor, however, there can be only one rotor if there is a single stator. The number of Hall Effect pickup switches may vary, for example, in the case of multiple stators of high resistant coils, the coils may be parallel to form a low resistant coil so that one Hall Effect pickup with one circuit may fire all of the stators at the same time. The number of magnets in both the timing wheel and the rotor may also vary in number as well as the size and strength of the magnets in gauss units. All types of magnets may be used. The number of winds on both the input and output coils on each conducting bar may also vary in number and in conductive material.

The motor generator, as shown in FIG. **1**, a top perspective view of a single stator, single rotor back EMF motor and is comprised of a means of providing energy, such as input battery **10** connected to power switch **11** (shown in FIG. **2**) and Hall Effect magnetic pickup switch **13**. Magnetic pickup **13** interfaces with timing wheel **12** to form a timing switch. Timing wheel **12** is comprised of four magnets **14** with the South pole of each said magnet facing outward to magnetic pickup **13**. Timing wheel **12** is fixed at one end of shaft **15**. Located on shaft **15** is rotor **16**. Rotor **16** can be of any size, said rotor containing four rotor magnets **17**. Said rotor magnets **17** are arranged in a manner so all have the same polarity. Opposite timing wheel **12** on shaft **15** is a means for work, such as a power take-off **18**. Rotor **16** is mounted in a fixed position with rotor magnets **17** in apposition with magnetized pole pieces **19***a* and **19***b*. Each pole piece **19***a* and **19***b* is connected to iron bars **20***a* and **20***b*. Iron bars **20***a* and **20***b* are connected by a permanent magnet **21**. A means for conduction is wrapped around iron bars **20***a* and **20***b* to form input coils **22***a* and **22***b*. Superimposed upon input coils **22***a* and **22***b* are output coils **23***a* and **23***b*. Output coils **23***a* and **23***b* are connected to full wave bridge first recovery rectifier **24***a*. First rectifier **24***a* is connected to battery **10**.

FIG. **1***a* is a perspective side view of the back EMF Motor Generator timing wheel **12** with Hall Effect magnetic pickup switch **13** in apposition individually to each of four magnets **14** as said timing wheel **12** rotates. Said magnets **14** have the South polarity facing outward with an equidistant separation of 90°.

FIG. **1***b* is a perspective side view of rotor **16** with four rotor magnets **17** with 900 equidistant separation and having the same polarity.

FIG. **2** is a schematic diagram of the motor generator circuitry showing input coil connections from input battery

10 through power switch **11**, transistors **30***a,b*, resistors **31***a–d*, through power supply lead **32** (VCC+) and to magnetic pickup **13**. Magnetic pickup **13** is in apposition with timing wheel magnets **14** located on timing wheel **12**. Off of magnetic pickup **13** is collector lead **33** and ground lead **34**. When current is reversed, it flows through resistor **31***e* and transistor **30***c* to input battery **10**. Input coils **22***a,b* send power to full wave bridge first recovery rectifier **24***a* which then sends power through switch recovery **27** back into the system, and/or to input battery **10**. Output coils **23***a* and **23***b* send power through single diode second recovery rectifier **24***b* to recovery battery **25**. In this particular embodiment, the value and type number of the components are as follows: Hall Effect magnetic pickup switch **13** is a No. 3020; transistor **30***a* is a No. 2N-2955; transistor **30***b* is a No. MPS-8599; and transistor **30***c* is a No. 2N-3055; resistors **31***a* and b are 470 ohms resistors; resistor **31***b* is a 2.2 K ohms resistor; resistor **31***c* is a 220 ohms resistor; resistor **31***d* is a 1 K ohms resistor; and recovery rectifier **24***a* is a 10 Amp, 400 volts bridge rectifier.

FIG. **3** is a box diagram showing the flow of voltage from input battery A, through recovery circuit B, switching circuit C and motor coils D. Motor coils D send available back EMF energy through recovery circuit B, and from B to recovery battery E and input battery A. Available back EMF energy can also flow from switching circuit C to recovery circuit B.

In multiple stator/rotor systems, each individual stator may be energized one at a time or all of the stators may be energized simultaneously. Any number of stators and rotors may be incorporated into the design of such multiple stator/rotor motor generator combinations. However, while there may be several stators per rotor, there can only be one rotor for a single stator. The number of stators and rotors that would comprise a particular motor generator is dependent upon the amount of power required in the form of watts. The desired size and horse power of the motor determines whether the stators will be in parallel or fired sequentially by the magnetic Hall Effect pickup switch or switches. The number of magnets incorporated into a particular rotor is dependent upon the size of the rotor and power required of the motor generator. In a multiple stator/rotor motor generator, the timing wheel may have one or more magnets, but must have one magnet Hall Effect pickup switch for each stator if the stators are not arranged in parallel. The back EMF energy is made available through the reversing of the polarity of the magnetized pole pieces thus collapsing the field around the coils and reversing the flow of energy to the recovery diodes, which is capturing the back EMF.

Individual motors may be connected in sequence with each motor having various combinations of stators and rotors or in parallel. Each rotor may have any number of rotor magnets ranging from a minimum of 2 to maximum of 60. The number of stators for an individual motor may range from 1 to 60 with the number of conducting bars ranging from 2 to 120.

What distinguishes this motor generator from all others in the art is the presence of a permanent magnet connecting the two conducting bars which transfer magnetic energy through the pole pieces to the rotor, thereby attracting the rotor between the pole pieces. With the rotor attracted in between the two pole pieces, the coils switch the polarity of the magnetic field of the pole pieces so that the rotor is repelled out. Therefore there is no current and voltage being used to attract the rotor. The only current being used is the repulsion of the rotor between the two conductive bar pole pieces thereby requiring only a small amount of current to repel the rotor. This is known as a regauging system and allows the capturing of available back EMF energy for use.

Finally, although the invention has been described with reference of particular means, materials and embodiments, it is to be understood that the invention is not limited to the particulars disclosed and extends to all equivalents within the scope of the claims.

What is claimed is:

1. A back EMF permanent electromagnetic motor generator using a regauging process for capturing available electromagnetic energy in the system comprising:

a. a means for producing a source of input energy to said motor generator, said energy conducted through a power switch and a magnetic timing switch;

b. a means for timing said motor generator, having a timing wheel connected to a shaft, said timing wheel comprised of one or more magnets, said magnets arranged so that the South polarity faces outward and is in apposition with said timing switch;

c. a rotor and a means for transferring a force on said shaft, said rotor containing magnets having the same polarity;

d. a stator comprised of two bars made of a magnetic conductive means, said bars connected by a permanent magnet and having a pole piece at one end of each said bar, said pole pieces thereby magnetized and in apposition with magnets of said rotor, said rotor positioned between said pole pieces;

e. an input coil comprised of a conductive material wrapped around each of said bars of said stator, said input coil connected to a circuit;

f. an output coil comprised of a conductive material wrapped around each of said input coil of said bars, said output coils connected to a recovery rectifier or diode;

g. said circuit for transferring electrical power, said circuit connecting said means for producing input energy to said power switch, said circuit comprising a pickup timing switch thereby providing an electronic voltage pulse to said circuit and then to said coils resulting in rotation of said rotor, said rotor turning said timing wheel to provide additional electronic voltage pulses to said circuit and then to said coils again, thereby providing a means for collecting available back EMF energy for storage, use or dissipation into the system.

2. The motor generator of claim **1**, wherein said input producing means is a battery.

3. The motor generator of claim **1**, wherein said magnetic timing switch is a Hall Effect magnetic pickup semiconductor.

4. The motor generator of claim **1**, wherein the number of rotors may range from 1 to 60.

5. The motor generator of claim **1**, wherein the number of magnets in said rotor has a range of 2 to 60.

6. The motor generator of claim **1**, wherein said magnetic conductive means may be ferrous, powdered iron, silicon steel, stainless magnetic steel, laminations of a conductive material or any other magnetic conductive material.

7. The motor generator of claim **1**, wherein the number of magnetic conductive bars has a range of 2 to 120.

8. The motor generator of claim **1**, wherein said means for transferring a force on said shaft may be a power take-off mechanism, gears, flywheels, belts or other methods of transferring force for the purpose of doing work.

9. A back EMF permanent electromagnetic motor generator using a regauging process for capturing available electromagnetic energy in the system comprising:

a. a battery connected to a power switch and a Hall Effect magnetic pickup switch, said magnetic pickup switch in apposition with a timing wheel, said timing wheel on a shaft;

b. a rotor and a power take-off means on said shaft, said rotor having four magnets of the same polarity, said magnets equidistant from each other;

c. a stator, said stator comprised of two iron bars connected by a permanent magnet and wrapped in a first copper conducting material to form an input coil that is connected to a circuit, on top of said input coil, there is wrapped a second copper conducting material to form an output coil with said output coil connected to a recovery rectifier or single diode, said iron bars further having a pole piece at one of each end of said bars, said pole pieces in apposition to said magnets on said rotor;

d. a circuit for transferring electrical power, said circuit connecting said battery to said power switch, said circuit comprising-said Hall Effect pickup switch thereby providing an electronic voltage pulse through said circuit and then to said coils resulting in rotation of said rotor, said rotor turning said timing wheel to provide additional electronic voltage pulses to said coils again, thereby providing a means for collecting available back EMF energy for storage, use or dissipation into the system.

10. A method of producing a back EMF permanent electromagnetic motor generator using a regauging process comprising the steps of:

a. placing a rotor containing magnets of the same polarity on a shaft with a timing wheel on said shaft;

b. placing in apposition to said timing wheel a Hall Effect magnetic pickup switch;

c. placing in apposition to said magnets of said rotor magnetized pole pieces of a stator, said stator comprised of two conducting bars connected by a permanent magnet; input coil connected a circuit;

e. on top of said input coil, wrapping a second conducting material to form an output coil, said output coil connected to a recovery rectifier or a single diode;

f. connecting a circuit for transferring electrical power, said circuit connected to a battery and a power switch, said circuit comprising said Hall Effect magnetic pickup switch thereby providing an electronic voltage pulse to said circuit and then to said coils resulting in increase rotation of said rotor, said rotor turning said timing wheel to provide additional electronic pulses to said circuit and then to said coils again, thereby providing a means for collecting available back EMF energy for storage, use or dissipation into the system.

Magnipulsion is Answer to Energy Crisis --- Bob Teal

By Doris Morgan

A retired enginer who works in a small shop at his home in Madison says he has invented a machine which might be the answer to the energy crisis.

B.R."Bob" Teal said he got the idea for what he calls his 'magnipulsion' engine when he was writing a still-unpublished science fiction novel.

After retiring from an engineering post in Hawaii with Ling Temco Vought in 1972, Teal and his wife Beatrice moved to Madison where he decided to try out his idea.

Entering Teal's backyard workshop, you see two stainless steel contraptions with wires and switches stuck here and there, his latest magnipulsion engines.

After explaining that the thing started with a car battery, Teal flips several switches which sends current to the magnets placed around the engine.

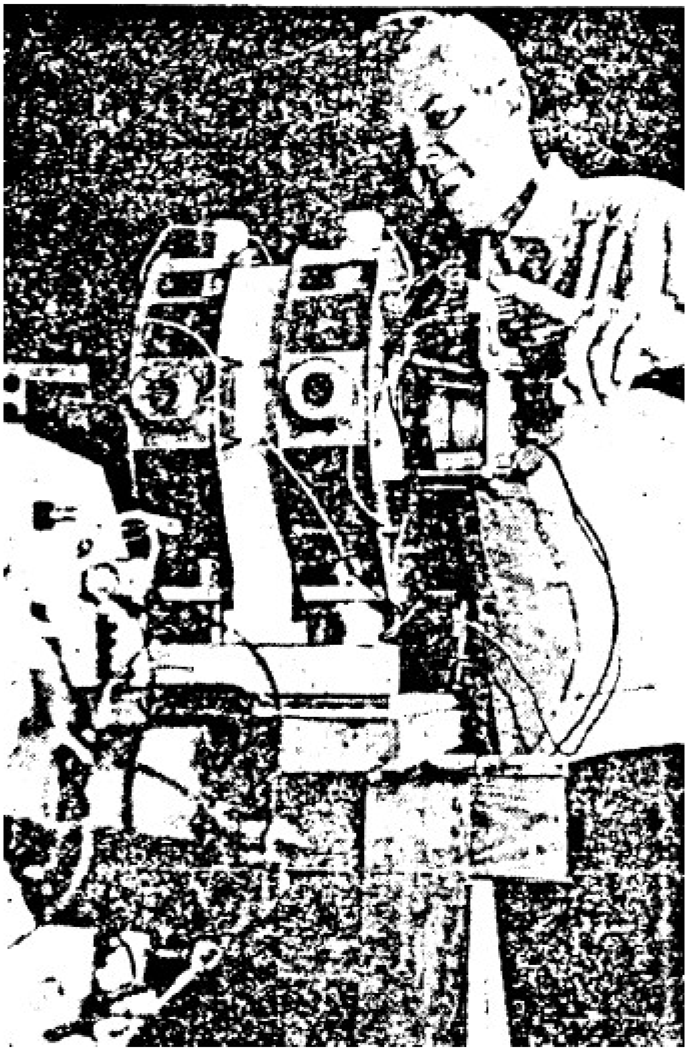
The one horsepower engine which sounds like a sewing machine while operating is the sixth in a series of electromagnet machines which Teal has developed since he began in 1972.

While the pistons pump up and down, much like a car engine through their magnetic cylinders, the pulleys spin around. Speed is reduced or increased by the flip of a switch that controls the power like the dimming of a light bulb.

“As it is now the machine can power shop tools, water pumps, or conveyers”, Teal said. “You can add horsepower by adding magnets”.

“I have built six engines and the latest will operate a 20-ton conveyer:, Teal said. He said he bought the car batteries more than a year ago and they have never been charged since.

Teal says his invention could save coal and oil which are now required to create electricity. “A small magnipulsion engine could operate a home central air conditioner for about 50 cents per day”, he said.



***Valdosta Times* (GA, 13 March 1977)**

Madison Man Builds New Engine

By Elizabeth Butler

The writing of a since fiction book eventually led a Madison resident to invent an electromagnetic engine which he says emits no pollution and takes little current to operate.

B.R. “Bob” Teal, a retired electronics engineer and author, has one patent and two pending on his invention.

“I wrote a science fiction book several years before retiring and I needed the story plausible --- an engine that emitted no pollution --- noise or air pollution --- so in my mind at the time I named it magnipulsion.

“Then after retiring in Honolulu in 1972 we came to Madison to live and having nothing else to do, I decided to build the engine. I built it and it works.”

Teal, 54, said scientists and engineers have come from all over the country and confirmed that it does what they consider to be impossible.

“I have built six engines and the latest will operate a 20-ton conveyor”, said Teal, who was born in Morven, NC, about 60 miles from Charlotte. “It operates fro a standard car battery and draws an extremely small amount of current. I bought the car batteries over a year ago and they have never been charged but once.”

Teal constructed his first engine of wood within a few weeks to see if it would work. The second engine was a crude one of metal and later he went to Jacksonville to get parts made for a prototype.

“I have dreams of building one large enough to run cars and boats”, teal said. “Judging from what I have done so far, I guess it would cost $400 or $500. There are very few moving parts so you would not need highly trained mechanics.”

Since the United Press International carried a story of his invention in May 1976, Teal has received hundreds of letters about the invention from around the world and has answered all of them.

“I have been attempting to get the government interested in hopes of getting a grant to build a shop and hire qualified personnel”, he said. “If I don’t succeed in the very near future in getting the grant, my attorney is preparing to go public and sell stock”.

Teal said telegrams from all over the nation and from foreign cities have been sent to President Jimmy Carter asking him to investigate the potential of the engine.

The electromagnetic engine is not the first invention for Teal, While working as an RCA engineer and filling a contract with the Navy in 1964, he was responsible for a classified invention which related to radio frequency cables and was valued at $50 million. “I didn’t get a penny for that”, said Teal, who has a letter from the navy Department giving him full credit for the invention.

Teal, who attended Wofford College in Spartanburg SC, and the University of Hawaii, retired from the Coast Guard after 20 years in 1962. He then worked for Ling Temco Vought, RCA, and finally went into Civil Service work with te Air Force, retiring in 1972.

During 1975-76 he wrote a column, “Is Justice?” for the Madison Carrier and last year he published a book of poems.

He is married to the former Beatrice Mae Cole of Baltimore MD, and they have two married children.

US Patent # 4,024,421

Magnetically Operable Engine or Power Plant

Benjiman Teal

Abstract

A magnetically operable engine or power plant embodying a rotary crankshaft having two or more offset cranks which, by means of respective connecting rods pivoted thereto, and also to the sliding cores or armatures of electromagnets, are actuated to apply torque to the crankshaft for driving purposes. Electrical current is supplied to the magnet windings by fixed distributor switches which are successively operated by one or more cams effectively mounted on the crankshaft, the switches receiving pulses of current in timed relationship and in such a manner that torque is continuously applied to the crankshaft.

Description

The present invention relates to a magnetically operable engine or power plant which, in a general way, functions in the manner of an internal combustion engine in that it employs a rotary crankshaft having offset cranks which derive their motion from power driven reciprocating members. Unlike a conventional combustion engine, the reciprocating members, instead of being motivated by the explosion of combustible gases in a combustion chamber, are caused to reciprocate by magnetic attraction, such members being in the form of cores or armatures which are associated with electromagnets, there being at least one magnet for each crank. Motivating current impulses are successively supplied to the various magnets by distributor means embodying respective normally open circuit making and breaking devices which are successively closed by one or more cams that rotate with the camshaft. The basic principle involved in thus applying torque to the crankshaft may appropriately be referred to as "magnipulsion" (a coined word) and such term may be employed where appropriate throughout this specification.

The present magnetically operable engine or power plant is capable of being used as a power source in connection with a wheeled automotive vehicle of either the passenger-carrying type or as a toy automobile. It is also capable of being used as a fixedly mounted power plant for driving adjacent machinery of various sorts but, irrespective of the particular use to which the invention may be put, the essential features thereof are at all times preserved.

The provision of an engine which is extremely simple in its construction and which therefore may be manufactured at a low cost; one which is comprised of a minimum number of parts, particularly moving parts, and which therefore is unlikely to get out of order; one which is rugged and durable and which therefore will withstand rough usage; one which is smooth and silent in its operation; one which is capable of ease of assembly and disassembly for purposes of inspection of parts, replacement or repair thereof; and one which otherwise is well adapted to perform the services required of it are further desirable features which have been borne in mind in the production and development of the present invention.

The provision of an engine or power plant such as has briefly been outlined above, and possessing the stated advantages, constitutes the principal object of the invention. Numerous other objects and advantages of the invention, not at this time enumerated, will become readily apparent as the nature of the invention is better understood.

In the accompanying two sheets of drawings forming a part of this specification, one illustrative embodiment of the invention has been shown .

In these drawings:

Referring now to the drawings in detail, and in particular to FIGS. 1 and 2, a power plant or engine constructed according to the invention is designated in its entirety by the reference numeral 10 and it embodies in its general organization a chassis or framework 12 which serves to rotatably support an elongated crankshaft 14 on which there is mounted a relatively massive flywheel 16 in the medial region thereof. A pair of pulleys 18 on opposite sides of the flywheel 16 have associated therewith respective drive belts 20 which may extend to a suitable transmission (not shown) in the case of a wheeled automative vehicle, or to the input drive element in the case of a stationary equipment which is to be driven by the power plant.

The framework 12 is comprised of an upper rectangular frame having longitudinal frame members 22 and 24 and transverse frame members 26 and 28, and a lower rectangular frame having longitudinal frame members 30 and 32 and transverse frame members 34 and 36. The framework 12 further includes a pair of intermediate posts 40 and front and rear vertical intermediate posts 42 and 44 respectively. A series of longitudinal struts 46 and transverse struts 48 extend variously between the posts 38, 40, 42, and 44 and establish an intermediaterectangular frame a slight distance above the lower rectangular frame 30, 32, 34 and 36.

A pair of bearing assemblies 50 are supported upon transverse support bars 52 and 54 and serve to rotatably support the crankshaft 14. Such crankshaft is provided with crank arms 56 and 58 on opposite sides of the flywheel 16 and with offset cranks 60 and 62. The crank 62 is connected by means of connecting rods 64 and 66 to respective electromagnets M1 and M2 which are fixedly mounted on the framework 12, while the crank arm 60 is similarly connected by connecting rods 68 and 70 to respective electromagnets M3 and M4, all in a manner that will be made clear presently.

The various electromagnets M1, M2, M3 and M4, together with their associated connecting rods 64, 66, 68 and 70 are substantially identical and therefore a description of one of them will suffice for them all. Accordingly, the magnet M1 (see also FIG. 5) embodies a magnet casing or shell 72 within which there is disposed a magnet winding 74. An armature or core 76 is slidably disposed within the casing 72 and is pivotally connected as indicated at 78 to the associated connecting rod 64. The remaining magnets M2, M3 and M4 are similarly connected to their associated connecting rods

The magnet M1 is mounted in a vertical position upon an upper shelf member 80 while the magnet M2 is mounted in a slightly inclined position upon a lower shelf member 82. As best shown in FIGS. 1, 2 and 3, the magnet M2 is seated upon a wedge-shaped base plate or block 84 which serves to misalign the axis of the magnet M2 from the axis of the magnet M1 by a small angle for a purpose that will be made clear presently. The magnet M3 is mounted in a horizontal position by means of a support member 86 while the magnet M4 is similarly mounted in a substantially horizontal position by means of a support member 88, the axis of the magnet M4 being slightly misaligned with respect to the axis of the magnet M3 likewise for a purpose that will be set forth subsequently.

Referring now to FIGS. 2, 3 and 4, one end of the flywheel 16 carries a cam 90 which is designed for successive engagements with a pair of substantially diametrically opposed microswitches S1 and S2 which are carried at the ends of a pair of horizontal supporting bars 94 and 96 respectively. Similarly, the other end of the flywheel 16 carries a cam 92 which is designed for successive engagement with a pair of substantially horizontally opposed microswitches S3 and S4 which are carried at the ends of a pair of horizontal supporting bars 98 and 100 respectively. As will become more readily apparent when the operation of the herein described magnetically operable engine or power plant is set forth in connection with the circuit diagram of FIG. 6, the arrangement of the various cams and microswitches is such that upon rotation of the crankshaft 14 and flywheel 16, the contacts associated with the microswitches S1, S3, S2 and S4 will become individually closed, successively and in the order named.

Considering now the operation of the herein described magnetically operable engine or power plant 10, and with reference to FIG. 6, it will be assumed that initially the position of the crankshaft 14 is such that, as shown in FIG. 3, energization of the magnet M1 will swing the crank 62 upwardly at such time as the cam 90 engages the microswitch S1. Closure of the C1 contacts associated with the switch S1 will establish a circuit leading from the negative side of the battery B, through the master switch MS, through leads 11, 13, magnet M1, leads 15, 17, contacts C1 of the switch S1, and leads 19, 21, 23 and 25, back to the positive side of the battery B. Energization of the magnet M1 will draw the core or armature 76 (FIG. 5) into the shell 72 and thus place the connecting rod 64 under tension so as to pull the crank 62 upwardly, thereby placing the crankshaft under torque for motivating purposes.

At approximately 90.degree. in the engine cycle, the cam 90 will engage the switch S3 and closure of the contacts C3 thereof will establish a circuit from the master switch MS through lead 27, magnet M3, leads 29, 31, C3 contacts of the switch S3, and leads 33, 35 back to the battery B, thus applying torque to the crankshaft 14 by placing the connecting rod 68 under tension.

At approximately 180.degree. in the engine cycle, the cam 90 will engage the switch S2 and closure of the C2 contacts thereof will establish a circuit from the master switch MS through leads 11, 37, magnet M2, leads 39, 41, contacts C2 of the switch S2, and leads 43, 23, 25 back to the battery B, thus applying torque to the crankshaft 14 by placing the connecting rod 66 under tension.

At approximately 270.degree. in the engine cycle, the cam 92 will engage the switch S4 and closure of the contacts C4 thereof will establish a circuit from the master switch MS, through lead 47, magnet M4, lead 49, C4 contacts of the switch S4, and leads 51, 43, 23, 25 back to the battery B, thus placing the connecting rod 70 under tension and applying torque to the crankshaft 14. The cycle is repetitious.

As shown in FIGS. 1 and 2, a control panel 102 is associated with a container or box 104 for the battery B and such panel may be provided with the aforementioned master switch MS and an indicator 106 which may disclose the amperage of current flowing from the battery B. Four push button switches PB1, PB2, PB3 and PB4 may also be provided on the control panel 102 and, as shown in FIG. 6, such push button switches are arranged so that they operate upon closure thereof to establish shunts across the respective microswitches S1, S2, S3 and S4 so that an initial momentary closure of a selected push button switch on a trial and error basis may cause torque to be applied to one or the other cranks 60 or 62 for initial application of torque to the crankshaft 14 in the event that neither crank is in a favorable position for engine starting at the time that the master switch MS is initially closed.

It is to be noted at this point that although the cams 90 and 92 are disclosed in FIG. 2 as being disposed at approximately 180.degree. from each other on the flywheel 16, such cams appear in FIG. 6 as being 90.degree. apart. It should be understood however that the disclosure of FIG. 6 is purely schematic and is intended to illustrate only the sequence of operation of the four switches S1, S2, S3 and S4 under the control of the cams 90 and 92 and that the front and rear end faces 16F and 16R shown in FIG. 6 rotate in the same direction since they do not represent front and rear end faces in the sense that they are illustrated in FIGS. 3 and 4. In other words, FIG. 6 is predicated solely upon the sequence of microswitch operation and does not represent a true positioning of parts such as is disclosed in FIGS. 1 to 4 inclusive. It is also to be noted that by reason of the slight axial misalignment of the magnets M1 and M2, and of the magnets M3 and M4, continuous crankshaft movement is effected since at no time will the engine or power plant 10 attain a position of dead-center where closure of the master switch crankshaft 14.

The invention is not to be limited to the exact arrangement of parts shown in the accompanying drawings or described in this specification as various changes in the details of construction may be resorted to without departing from the spirit of the invention. For example, the precise placement of the various cams 90 and 92 and microswitches S1, S2, S3 and S4 on the flywheel 16 and framework 12 may be varied if desired as regards their angular relationship with respect to one another, the only criteria being the attainment of sequential operation of the switches in such a manner that torque is applied to the crankshaft 14 at all times by at least one of the four connecting rods. Furthermore, if desired a greater or lesser number of electromagnets suitably mounted on the framework 12, together with a commensurate modification of the nature of the crankshaft 14, may be resorted to if deemed appropriate. Therefore, only insofar as the invention has particularly been pointed out in the accompanying claims is the same to be limited.

US Patent # 4,093,880

Magnetically Operable Engine

6 June 1978

Benjiman Teal

Abstract

A combination device for developing a mechanical output from electrical energy which uses at least one electrical magnet solenoid, and preferably a plurality of same, together with an associated timing mechanism for actively controlling the time and degree of energization of said electrical magnet(s). Preferably at least one of the electrical magnetic solenoid structures may be provided with an air compressor structure for increasing the normal atmospheric pressure to a desired pressure.

Description

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates generally to devices changing electrical energy into mechanical energy in a form which may be used to power useful work applications.

2. Description of the Prior Art

A common problem with known type devices for converting electrical energy into mechanical energy is that they often times are very inefficient and waste a lot of energy in the conversion process. This is a great disadvantage in today's age when conservation of energy is extremely important.

Another problem with known type engines utilizing electrical magnets for part of their structutre is that the associated slidable solenoid mechanism is normally used just for converting the electrical energy into mechanical drive output without any direct actuation of useful work structure directly from the movable solenoid armature.

SUMMARY OF THE INVENTION

An object of the present invention is to provide an electrical magnetic operated power engine for converting electrical energy into useful mechanical energy.

Another object of the present invention is to provide a magnet powered engine having a plurality of electromagnetic solenoids with electrical coils and movalbe solenoid armatures therewithin arranged in substantially the same plane and connected with associated mechanical transfer mechanism to convert the movement of the electric solenoid armatures into the desired mechanical power. A suitable timer structure is also associated with this mechanical structure for controlling the time and degree of energization of the respective electric-magnet coils for the various electro-magnetic solenoids.

A further object of the present invention is to provide an electro-magnetic solenoid engine structure which incorporates and has combined therewith a mechanical sturcture for compressing air at atmospheric pressure to a greater pressure for direct conversion of the electrical source power into a useful product.

An additional further object is to provide an electromagnetic type engine which includes a plurality of electromagnetic coils in assoicated timing structure arranged in substantially the same plane, with two or more of these structures being stacked one upon the other in order to greatly increase the overall output of the entire structure.

The magnet power engine and air compressor combination of this invention has a number of new and unique features not known or used before. A basic support structure is provided having at least one bank of electro-magnetic solenoids arranged in substantially the same plane thereon. Each electro-magentic solenoid has a slidable and movable solenoid armature therewithin which is mechanically operated and connected to associated mechanical structure for converting the slidable movement thereof into a rotary shaft power output. A timing mechanism is also associated with this mechanical structure for appropriately connecting the electrical power source to at least one electromagnetic coil, and preferably a plurality of same, so that they will operate in proper timing for directing the slidable movement of the solenoid armature back and forth within the solenoid electro magnetic coil.

Also preferably combined with the aforesaid structure is an attachable cylindrical sleeve structure having a slidable piston therewithin and appropriate air valves for connection with the slidable solenoid armature so that useful work may be directly accomplished such as by compressing atmospheric air to a much higher desired pressure. This structure may be provided for each of the electro-magnetic solenoids, or on less than all of same.

These together with other objects and advantages which will become subsequently apparent, reside in the details of constructuon and operation as more fully hereinafter described and claimed, reference being had to the accompanying drawings forming a part hereof, wherein like numerals refer to like parts throughout.

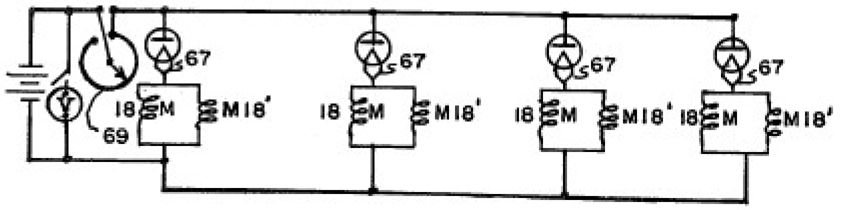

FIG. 8

DESCRIPTION OF THE PREFERRRED EMBODIMENT

Looking at FIG. 1 of the drawings, reference numeral 10 indicates one bank of the electro-magnet motor of this invention. Looking at FIG. 2, two banks, one being stacked on top of the other may be seen.

Each bank basically is provided with a support structure 12 approximately square in shape with two of said support squares being provided for each engine bank. Appropriate spaces separate these support squares and together with nuts and bolts 14 form the basic support for each engine bank. As may be best seen in FIG. 2 the lower must bank is supported from any desired support surface by means of another support structure 22 with appropriate bolts 24. Support brackets 17 appropriately mounted on the respective squares 12 support the respective electro-magnet coils 18 therebetween. As seen in FIG. 1, this bank is provided with four electro-magnets appropriately spaced at the four corners of the square support frame. It has been discovered in actual practice that a bank of four electro-magnets works extremely well and provides a fairly balanced power output. Each electro-magnet coil 18 is provided with a suitable number of coil windings to effect the slidable movement of a centrally mounted solenoid armature 28 therewithin.

As best seen in FIG. 3, the one end of the solenoid armature 28 is appropriately center tapped for reception of a threaded screw 32 therewithin. This threaded screw 32 appropriately secures a block of aluminum or other non magnetic material 30 to this end of the armature. The block 30 forms a connecting link through suitable apertures provided therewithin and by means of a connection of a pin 34 with locknut 36 thereon to a connecting rod portion 38. This connecting rod 38 is suitably pivoted at 39 to the disc 35 which is mounted so as to transfer power to the connecting rod crank 25. The connecting rod crank 25 is suitably formed at appropriate points along a crank-shaft 15 as best seen in FIG. 2. If only a single engine bank is to be used just a single crank-shaft throw 25 is necessary, but for an engine having two engine banks as seen in FIG. 2, two such throws are required and as the number of banks increases, the corresponding number of crank-shaft throws is necessitated.

In operation as the electro-magnets are energized in proper sequence, the electrical input will be transformed into mechanical output through the afore described mechanism. In order to assure that the electro-magnets are operated in proper time relationship a timing mechanism is also provided. Such timing mechanism is indicated in general by reference numberal 50 in FIG. 2, and shown in enlarged detail in the cross-sectionalview of FIG. 4.

A mechanical coupling unit 51 appropriately supports the timing mechanism at one end of the electro-magnet motor and by means of appropriately threaded bolts 54 support plates 52 therefrom. The plates 52 are spaced from each other and each supports thereupon insulator blocks 58. These blocks support electric connectors 56 which in turn connect with bias springs 57 and electrical brushes 61. The insulating blocks 58 are fixed upon the supports 52 and are non-roatable, but the center disc 59 supported therebetween is mounted for driven connection from the end of the crankshaft 15. Each side of the rotatable disc 59 is provided with conducting segments 63 which are internally connected to each other so that the electrical energy connected to input contacts 56 on the upper side of the timing mechanism may be appropriately transferred through springs 57, brushes 61 through the segment 63 to the lower brushes 61, springs 57' and contacts 56' which are appropriately connected to the respective electro-magnets of the engine. Of course the segment 63, 63' are appropriately designed for the number of electro-magents used for the respective banks as well as the total number of such banks and are connected by appropriate wiring, not shown, in such a manner that each electromagnet will be energized for substantially the full stroke of its slidable solenoid armature and thus transfer the maximum of energy from electrical form to mechanical form.

FIG. 5 shows an electrical schematic with one of the electro-magnet solenoids having coils 18 and 18' indicated and with contact brushes 61 and timing segment 63 indicated schematically. Also shown across the timing contact 61, 63 are resisters and capacitors in parallel. The purpose of this is to minimize arcing of the make and break contacts of the respective brushes and contact segments.

FIG. 8 shows an alternative form of energizing the electro-magnet solenoids which is generally referred to as a solid-state switching and which is actually performed by diodes 67. The current entering the solenoids may be regulated by the rheostates 69 as shown in FIGS. 5 and 8.

Looking at FIG. 2 on the right side thereof, an air compressor sleeve 46 is shown appropriately secured by clamp means 66 to one of the electro-magnet structures. FIG. 6 shows this structure in enlarged detail. The outer end of the solenoid armature 28' is appropriately tapped for reception of a threaded bolt 72 therewithin The enlarged head of the threaded bolt together with a spacer sleeve 73 appropriately support a flat piston member 75. This piston member 75 may be appropriately provided with a compression ring 76 of conventional type. The clamp structure 66 to secure the sleeve 46 at the end of the electro-magnet is preferably provided with a thumb nut 68 or the like to secure same. The other end of the sleeve 46 has an outstanding flange periphery 47 for suitably securing a cylinder head 48 thereto. Appropriate bolts and nuts 49 together with suitable gaskets form an air-tight seal between the head 48 and the sleeve 46, 47. For proper compressing operation to be effected, it is necessary that suitable valve mechanism be associated with this compressor structure. This is in the form of a flexible diaphragm 86 which is secured around the circumference thereof between the head 48 and the flange bracket 47. At the center of the flexible diaphragm 86 is mounted a cone shaped protrusion 87 which together with an aperture 88 provided in the center of the head 48 functions as a one way intake air valve. That is, when the piston 75 is moving away from the head and the diaphragm, air will be drawn into the inside of the cylinder sleeve 46 through the aperture 88, and then in turn on the compression stroke of the head 75 the protrusion 87 will seal aperture 88 and then the escape of air out this opening wil be prevented. Another outlet 90 appropriately connected by tubing 92 to a one way check valve 94 provides an outlet for the compressed air and yet prevents backflow thereof. All or some of the connecting tubing 92 may be of a flexible nature as desired.

As can be readily envisioned, when one or a plurality of the electro-magnets are provided with such air compressor sleeves, a direct useful engine output in the form of air under high pressure is achieved. As so constructed, the entire apparatus may be used solely for providing compressed air for various useful purposes. However, by connecting suitiable work apparatus to the output of crank-shaft 15, near the timing mechanism 50, other devices may be driven from this electro-magnet structure.

The foregoing is considered as illustrative only of the principles of the invention. Further, since numerous modifications and changes will readily occur to those skilled in the art, it is not desired to limit the invention to the exact construction and operation shown and described, and accordingly all suitable modifications and equivalents may be resorted to, falling within the scope of the invention.

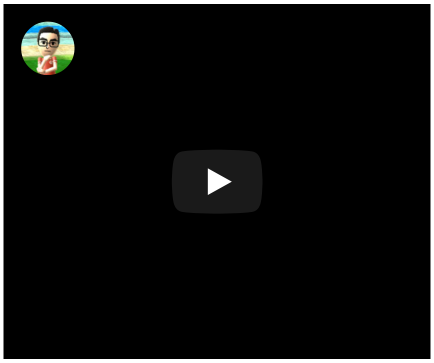
13th March 1 meter loop AM crystal radio step by step construction guide

1 meter loop AM crystal radio step by step construction guide



Steps to Design an AM crystal radio

1. The band & frequency range 2. Choose the tuning method3. Choose the Variable Cap.4. Calculate the Inductance 5. Make the coil6. Connect the circuit and Test

Checkout the above video for the instructions and testing.
And comparison of different tuning method, Variable Inductors and Variable Capacitors.

3rd March What do you need to know to build a crystal radio

Thanks for your interests in Crystal Radios.

Many people asked me how to build one. Many people tried and failed to receive any signals. I hope the following will give you the tips to avoid many of the challenges and let you enjoy the charm of having a functioning crystal radio. A radio that functions without batteries.

Here are the basic preparation work to build your first Crystal Radios or Power Free Diode Radio or Power Free MOS FET radio or Power Free LED Radio.

A Crystal radio i same as a regular radio you can purchase from the electronic shops, minus any form of electrical implications. Some Crystal radio uses physical audio amplification by using a horn, but no high frequency nor audio frequency amplifications.

A Crystal radio requires the following:
Antenna
Earth
Coil
Capacitor (s)
Detector (Crystal, Diode, zero voltage MOS FET, LED).
headphone or earbud

Transformer for impedance matching (optional)

But No batteries

1. Antenna and Earth.
Unlike a conventional radio that has bultin amplifications powered by batteries, crystal radios just turn whatever radio wave it receives from the antenna and coil into electrical signals without signal amplification and without using any batteries or other forms of electricity supply.

You need to be very close to the transmission station to be able to do this. Usually within 30KM.
For my case, my apartment is within 10 KM from two different radio transmission stations.
While some people can receive stations from 50KM or 100KM or 1000KM away, they have very long antennas (talking about miles) and earth system which is impossible to achieve in a city like HK.

The living environment in most Asian cities populated with concrete jungles is not too suitable for receiving crystal radio directly from your home.
Most city dwellers live in high rise apartments with not much open view between your apartment and the radio transmission stations.
If your apartment is blocked by another high rise apartment in the direction of the transmission stations, you will not be able to receive any stations through your crystal radio.
You can see this link for the AM and FM radio transmission stations in the world. This one is in particular about HK.

Link:
http://worldradiomap.com/hk/hong-kong [http://worldradiomap.com/hk/hong-kong]

http://www.asiawaves.net/hong-kong-radio.htm

For AM crystal radios , you will need a very long antenna and a good earth connection.
Depending on how close your apartment is from the target transmission stations, the antenna need to be at least 5M, or even 10M or more). If your apartment is facing the same direction of the radio transmission stations, you can hang a cable down from your window as an antenna. However that will alienate your neighbours as they may think you are hanging IP cameras to spy on them. It may also get yourself into trouble with the building management staff, or even the law enforcement units in your country.

If you are real close to the transmission station and even have a clear line of sight view of the transmitter (e.g. if you travel close to the transmission station), you can use any thread of 1 M or longer or a telescopic radio antenna to receive the AM radio.

For FM radio reception, you must be very close to the FM transmission station, e.g. < 5KM. As FM signals reduces much faster in distance than AM.
A good passive FM Yagi antenna with the main beam (called the radiator) measured 1.7M is required for good reception from home.
Or an active FM radio antenna with HF signal amplification is required. However this defeat the purpose and the charm of having a crystal radio in the first place. The no. 1 charm of having a crystal radio to me is to listen to radio without batteries or any other form of electrical power.

If you are very close to the FM transmission stations, e.g. for my case, around 3KM from the FM transmission station, you can get quite good a reception using a 1.2 meter to 1.8 meter telescopic radio antenna. FM radio signal reception is an art. Standing in different places just a few feet apart, or turning your antenna just a few degrees away, or holding your headphone cable horizontally versus vertically will effect the signal quality or even tune you to a different station.

Earth ((a.k.a. Ground),) is not required by FM radio, However, some tests show that for FM radio, if you tie one end of your coil to a thread that is lowered to touch the ground, the reception can be improved.

Earth will enhance reception for AM and SW radios. However, if the signal from your antenna is already strong enough, you may not need an earth.
For weaker reception, earth will definitely help.

If your apartment is still using metal water pipe, congratulations. You can simply connect your ground to that water pipe, just connect a few turns of bear wire (without the rubber skin) onto the water pipe. Unfortunately all your water pipes are made of plastic (e.g. many new buildings in mainland China as they build buildings with much cheaper materials), then you may be able to try some gas pipe, or electrical each (be careful of electric shock in case you incorrectly connect to the line that carry electricity instead of the earth/ground. In a worst case, you can try pulling a second antenna and use that as earth. Sometimes that may improve the reception.

The other alternative is to build a Loop crystal radio (0.5M to 1M in diameter, e.g. the size of an umbrella) , where the coil itself can replace the function of the antenna if you are close enough to the transmission station (< 10KM) and have a direct view to the transmission station that is not blocked by another high rise building. However some people are able to pick up radio stations through the reflected radio waves bouncing off the walls of the buildings eventhough they are blocked.
The draw back is you'll need more money to buy the long wires in order to build one. E.g. for a diameter of 1M, you need to have at least 40M of wires to have 12 turns for the coil, roughly HKD 100,

2. Head phone.
You will need a very sensitive head phone. The earbuds and headphones we used to listen to music from your smart phone or your hifi at home, will produce a very faint sound.
As these are designed for receiving a high power output, focus is on the quality not sensitivity.
You will need special head phones for crystal radio reception.
These can be purchased from taobao, or you can make your own using a ceramic piezo-electric buzzer (still available in the ShimshuiPo IpLiu Street shops（華輝）, the plastic tip of a ball pen,a silicon earbud cushion, glue, some wires and the headphone jack.
You can refer to my video on how to make one.

Link: https://www.youtube.com/watch?v=k3HsVlxR2tA [https://www.youtube.com/watch?v=k3HsVlxR2tA]

If impedance of your headphone does not match with the of the detector, you will need a step up or step down transformer for impedance matching.
Impedance matching is very important for crystal radio.
As Crystal radio has no signal amplification, we need to maximise the efficiency of the transfer from one stage to the next. and that require impedance matching to ensure we transfer all the energy down to the next stage of the circuit. Any impedance mismatch will mean energy loss, and lowered output, softer sound.

3. Coil

For AM, radio,
You can build a small coil (0.01M to 0.1M) to go with a long antenna and earth, or a big loop coil (0.5M to 1M diameter, see above)
You can use insulated magnetic wire (available from the DIY shops
Due to skin effect (radio signals only travel at the surface of the wire instead of the core), Litz wires that have multiple insulated smaller wires wrapped within a cotton thread will perform much better, almost doubled in terms of loudness than the solid Magnet wire
Each one has up to 660 tiny wires each measures 0.04mm in diameter. These are available in the taboo shops, around HKD 150 per roll that is enough to make one big coil for umbrella loop radio.
For small coils, the one with 60 tiny wires each 0.04mm can be used to wind on a dark ferrite rod (1cm diameter), the ones you see on most conventional radios.

measure Capacitance as well.
For AM radio, inductance required is from 180uH to 510uH, depending on the size of capacitance you match with.
180uH match with 512pf capacitor
330uH match with a 365pf capacitor
510uH match with a 220pf capacitor.

4. Variable capacitor v.s. fixed capacitor

Variable capacitors is also very important for a good radio. It is the knob that you turn to tune to the frequency for your crystal radio.

Air insulated variable capacitor made of copper has the highest Q factor. It's available in taboo but hard to find and very expansive > HKD 150.
Smaller versions of these < 20pf can be used for FM radio (HKD 20).

Next is the air insulated variable capacitor made of aluminium. Around HKD 30-50 depending on the size.
In general the bigger ones with the divider wider apart has a high Q.
Q is a factor that measures how good is the efficiency (sensitivity) and accuracy (selectivity) in transferring radio wave signals to electric signals.
The conventional plastic variable capacitor we see on the conversational radios will also work, but loudness will be diminished a bit (at least 30% less loud).

Alternatively, you can use a fixed capacitor, but vary the inductance of your coil to tune to different frequencies.
You tune the inductance by different methods:
1. Move the coil in or out of the ferrite stick. Very easy to do, see my videos.
2. Vary the length and separation of the turns within the coil (much harder to achieve practically).
3. Wind two coils. Then overlap these two coils on top of one another and the total inductance of the these two coils in series = the addition or subtraction of the two coils. Addition if they are facing the same direction (e.g. clockwise), subtraction if they are different direction (e.g. anticlockwise on one coil which is laid on top of a clock wise coil). The amount.to add or subtract also depends on how much of the area of the two coils are overlapping.

5. Detector.

Detector is the component that translate high frequency radio signals to Audible signals.
This conversion is called demodulation.
The action taken by the detector is really simplify only allow electric current to flow in one direction and stop current flow in the opposing direction.
This way, only the position half of the radio signal is allowed to pass through.
The the audio signal will be able to be reproduced by the headphone.

There are different types of detector.
I list them here in term of the performance. Best performance first.
With the exception of vacuum tube, all can function without battery or mains electric power.
This the charm and magic of crystal radio, or battery free radio.

Zero voltage MOS FET
Diode
LED (only works in very strong signals (> 200uA), lits up during radio reception and glow according to the strength of the signal.
Vacuum Tube (that need to be battery powered to lit up the heating coil, but no power required for detection).
Crystal

The name "Crystal Radio" v.s "FET radio" v.s. "Diode Radio" v.s "power free radio"

There is constant debate over the name given to all kinds of radios that can operate without battery or other kinds of man made electrical power (solar cell, acid cell from fruit, hand-held push/pull power generator or mains power supply).

With newer form of detectors that we discover in recent years, besides genuine crystals with cat whiskers, zero voltage MOS FET e.g. 3DQ (3SK-143-Q), Diode (e.g. 1N34A), or even LED are used as detectors. Should we or should we not keep calling them Crystal Radios ?

My vote is to still call these Crystal Radios.
Simply as it simplifies a mouthful of words such as power free zero voltage MOS FET radio.
And Crystal radios reminds every one of the Charm of listening to radios without power.

[https://2.bp.blogspot.com/-25rUWT5Zm1c/VwG6b_FjUEI/AAAAAAAACfM/UG8R-49XUSsSH_LH6FY0cd0RJ-ObbZ-4g/s1600/IMG_6942.JPG]

I tried to create a loop antenna coil using soft flat cable with 20 x 1mm flat copper strips with good effect before (the one in the middle of the picture).

This time I found find a bigger soft flat cable with 6 x 3mm flat copper strips with a 2mm separation in between (the one on the left of the picture).
You can make a loop solder the copper strips together to make a single coil with 6 turns.
For use with FET (3SK143-Q), 1 turn is reserved for the S-pole of the FET.
Total inductance is 75uH when I mount the laps placed on a square frame made of PVC pipes measured 900 mm on each side.
This matches with 2 x 500pf variable capacity connecting in parallel making a 1000 pf Variable capacitor.
Result is quite good, though still not comparable with a coil made from 0.04x660 Litz wires of the same size.
However, this one is easy to make and quite portable. You can just roll them up and carry them anywhere.
Find some sticks to create a frame and mount it on top. Or hang it from a tree when picnicking.

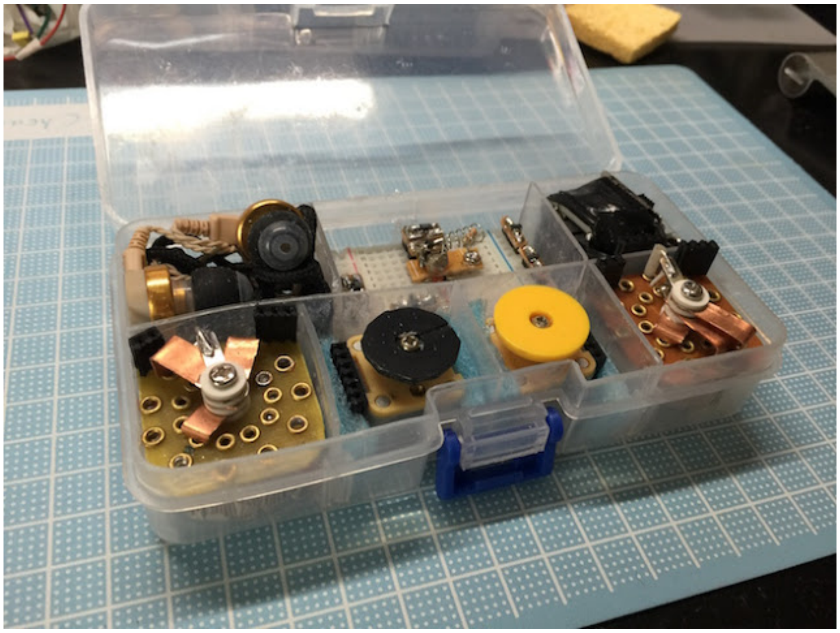
DIY Tiny portable crystal radio laboratory 135 x 70 x 30 mm

Here are the pictures:



Inspired by skywave's traveling crystal set. I built this DIY Tiny (135 x 70 x 30 mm in size.) portable crystal radio laboratory.

I found a tiny sorting box made of low loss material (pp) and start to put things in:

- a couple of the DIY tiny multi-pole rotary switches (that I built) soldered in with the ferrite coils. I used 31mm ferrite core with100u permeability and Litz wire of 0.04 mm x 60 threads (see the picture below for the no. of turns).The shortest handle of the rotary switch selects the number of turns of the antenna coil. The longest handle selects the tapping point of the detector in the tank coil. The one in the middle selects the number of turns of the tank coil to match with the tuning capacitor
- a couple of 2x270pf plastic variable capacitor.
- a pair of 150 ohm hearing aid ear buds (total 300 ohm).
- a tiny 200K to 300 ohm audio transformer that I purchased from taboo.com soldered in with switches for the different way to connect , e.g. 200k to 300 ohm for my hearing aid ear buds, or just connect 200K in parallel with my piezoelectric ear bud.

The transform can be improved as its not ideal to have impedance fixed at 200k. I am trying to open it up to see if I can add additional taps without breaking the hair thin wires inside.

- A breadboard with the following different types of detectors
-- Crystal
-- BAT85
-- 1N60
-- 1N34A
-- 1SS86 x 2
-- HSM 2820 x 2
-- HSM 2850 x 2
-- 3SK143-Q (*3DQ) x 2
-- 33K resistor to work with 3DQ.
- Connecting wires (hidden under the breadboard).
- Tiny 50uA DC current meter (stilling trying to find one. So far I can only find a tiny 500uA meter that does not move much as the crystal radio current is so small). If I ever find one, it'll take the place currently used by the earbud.

I tried this in the hotel room when traveling and got good results.
- Tested using my 700mm umbrella loop antenna.
- Tested by hanging 3 meters of horizontal wire at the top of the curtain inside the room. [https://4.bp.blogspot.com/-Uq_TZea4wT4/VwBnupV99NI/AAAAAAAACeQ/OMB8y1i7TUsNOj0Eox2Ag9o-DGAV79HJw/s1600/IMG_6921.JPG]

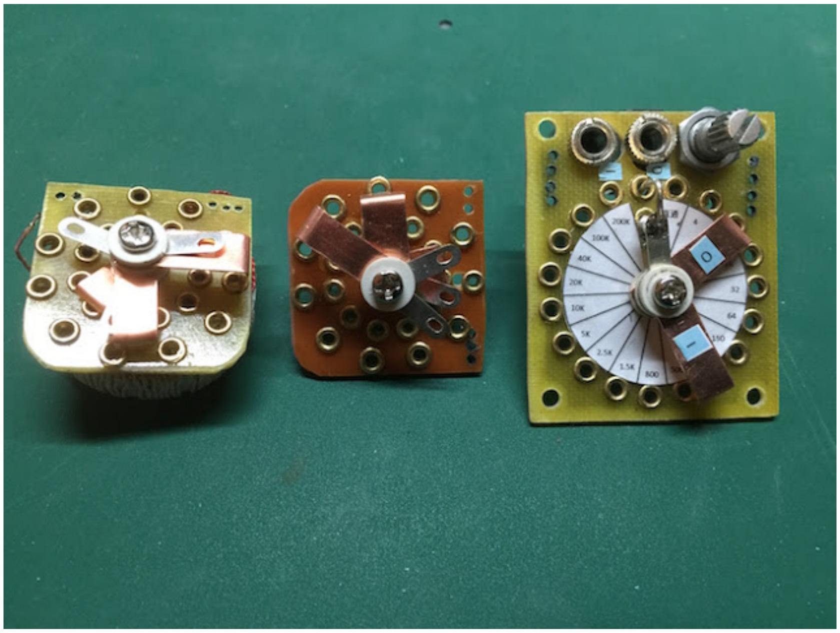
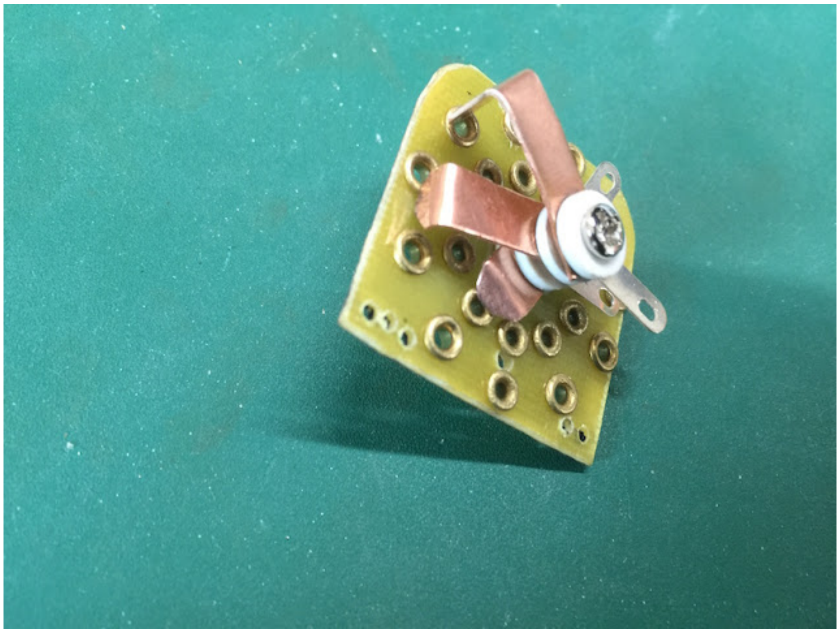
DIY dual pole 18 position switch for KPB-02 Impedance matching transformer

I DIY a dual pole 18 position switch for KPB-02 Impedance matching transformer and another dual pole 10 position switch for tapping a ferrite toroid coil.



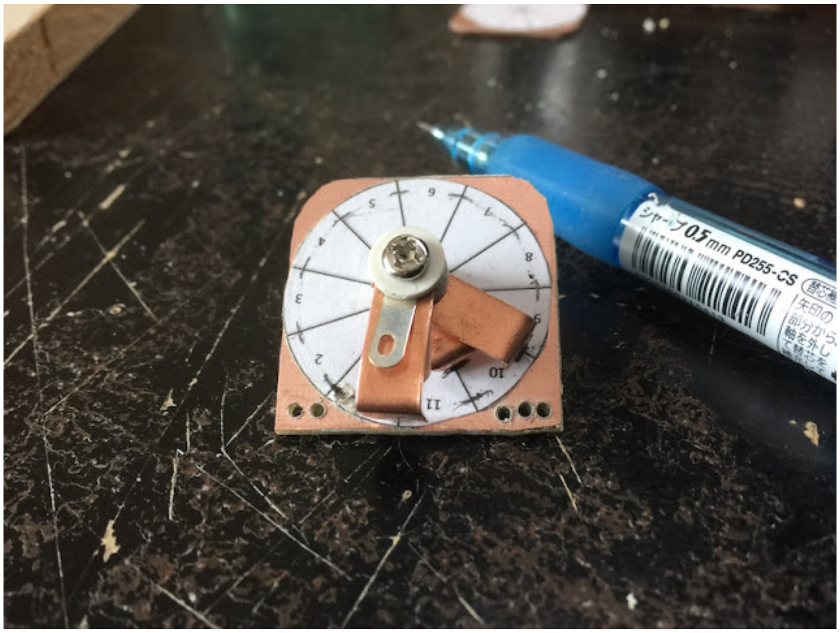
[https://4.bp.blogspot.com/-dsvWlUJsZt0/Vvk-gbMmwcI/AAAAAAAACcs/-LbWdW_k6e8ta4k6DiuVCZH_ajYONCfZg/s1600/IMG_6863.JPG]



[https://4.bp.blogspot.com/-qYMkNI_6DPA/Vvk-fnxCK5I/AAAAAAAACcg/yzmJHUAADoMOjk4C5BmEAOuawqsV-0rxA/s1600/IMG_6852.JPG]

I added another 3 pole 10 position switch for tapping the ferrite toroid coil.
1st pole for the tap on the antenna coil.
2nd pole for the tap on the tank coil for the variable capacitor for tuning.
3rd pole for the tap on the tank coil for the detector (divide).

Here are the pictures.



[https://3.bp.blogspot.com/-kcCmc8Jij4g/Vvk-b0wIukI/AAAAAAAACbQ/XcphLL3-pD06vlt2-2NPDkGd3U8wkGaaw/s1600/IMG_6822.JPG]

Vietnam Crystal Radio Test

I traveled to Vietnam, Ho Chi Minh City on the week of Mar 14 2016.

My hotel room is on 2/f, 3.5km from the broadcasting station for the voice of Vietnam (local state owned MW radio station) . Since the window is sealed, I have to rely on my umbrella loop antenna (0.8 meter diameter). I measured a dc current of 65uA from my Crystal set, so loud that I can plug in an 8 ohm headphone and still got reasonable loudness.

I also ran a series of tests using my tiny mobile crystal radio laboratory.

I brought my FM Crystal Set with the 1.2m extensible antenna too.
I could receive one station but weak and barely understood the broadcast.

Wearing my jacket crystal radio with a 400mm x 600mm loop antenna sewed into the back of the jacket, i could listen to the radios from within a bus traveling on the street using a 3SK143-Q crystal radio. You can see that at the end of my video.

I also visited the museum and saw some radio communication equipment used during the wars.

Purchased some nice wooden boxes that can be used to build some nice crystal sets. only USD 3.5 each.

I noticed that there are lots of antenna towers in Ho Chi Minh City. May be because the buildings are not tall enough, towers are needed to pull up the antenna to the right height. I guess most of these are for 3G mobile phone communication. I did see one super tall antenna that seems to match with my info about the location of the Radio transmission stations for the AM and FM radios.

Here are some pictures.

And the video of my crystal radio tests.

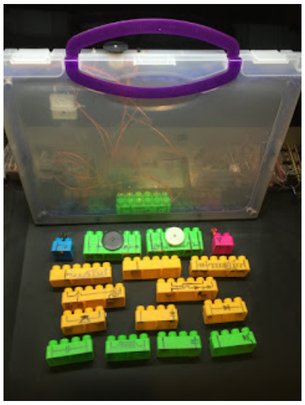
3D Building Blocks for Crystal Radio

Create 3D building blocks for crystal radios so kids and adults can experiment with crystal radios. There is also a portable case for you to take what you have created out on the street to listen to radio using the big loop antenna on the case.



[https://1.bp.blogspot.com/-D-Q1YX12uxc/VsRVN_XRCdI/AAAAAAAACTw/brRaIZomEp4/s1600/IMG_5678.JPG]

I have seen similar building blocks used to build lights, fans, and even robots, but not crystal radios. Though this is a low tech construction, I've spent weeks trying to figure out which building block is suitable (big enough to house the variable caps and ferrite sticks) and flexible with different length and height. Most importantly, how to make the connectors between the blocks so it's plug and play and yet the contacts are firm enough to be carried around.

I thought of using springs, but the extra turns for each connection may interfere with wireless signals. Finally settled with copper screws and elastic copper sheets that do the same magic as springs.

Portable 3DQ FM SW MW Crystal. Regen. Radio

I created a portable FM SW MW Crystal Set with region functions using a combination of big loop and ferrite toroids.

Dynamic Views theme. Powered by Blogger.

Components

S1 MW/SW Selection
S2 MW/SW Hi Band/Low Band Selection
S3 Switch attached to VR2, turn on for region adjustment or volume adjustment.
S4 Selection for FM or MW/SW and Regen or Battery Free Radio.
S5 Antenna adjustment switch
VR1 Volume or Regen effect adjustment. with S3 attached. Connect S3 to VR1 such that when resistance to 3DQ-S is the lowest, S3 will stay open.
L8 using a 1.5M 1/4 W resister as the frame, wind 30 turns of 0.07 or 0.1 mm magnet wire.
L9, L10 using a 1.5M 1W resister as the frame, wind 100 turns of 0.07 or 0.1 mm magnet wire.
C1 1pf-18pf butterfly high Q variable capacitor.
C2, C3, C4 3x500pf VR.
J1 connect to a reed headphone with impedance of 300 to 600 ohms.
3V CR2032 Button Battery for Regen.

L1 make a 120mm diameter C-shape loop (with a 50mm openning) using 12mm diameter soft copper pipe.
L2 make a 25mm diameter C-shape loop using 1 mm diameter silver plated copper wire. Wound in same direction as L1.
L3 make a 25mm diameter C-shape loop using 1 mm diameter silver plated copper wire. Wound in same direction as L1.

This Crystal Set can hook up to big loop coils or toroid coils.

For toroid coils:
L4 use a ferrite toroid with permeability of 100u (NXO100) diameter 37mm, height 7 mm, wind 50 turns using 175x0.04mm Litz wire.
L5 On the same toroid, using same type of litz wire, wind 10 turns in the opposite direction as L4.
L6 use a ferrite toroid with permeability of 100u (NXO100) diameter 31mm, height 7 mm, wind 12 turns using 1mm magnet wire.
L7 On the same toroid, using same type of magnet wire, wind 4 turns in the opposite direction as L6.

For big loops:

Dynamic Views theme. Powered by Blogger.

like winding on a toroid.
L5 On the same frame, using same type of litz wire, wind 1 turn in the opposite direction as L4.
L6 make a 1 Meter diameter C-Shape loop (with a 100mm opening) using 12mm diameter soft copper pipe.
L7 make a 0.5 Meter diameter C-Shape loop (with a 100mm opening) using 9 mm diameter soft copper pipe.

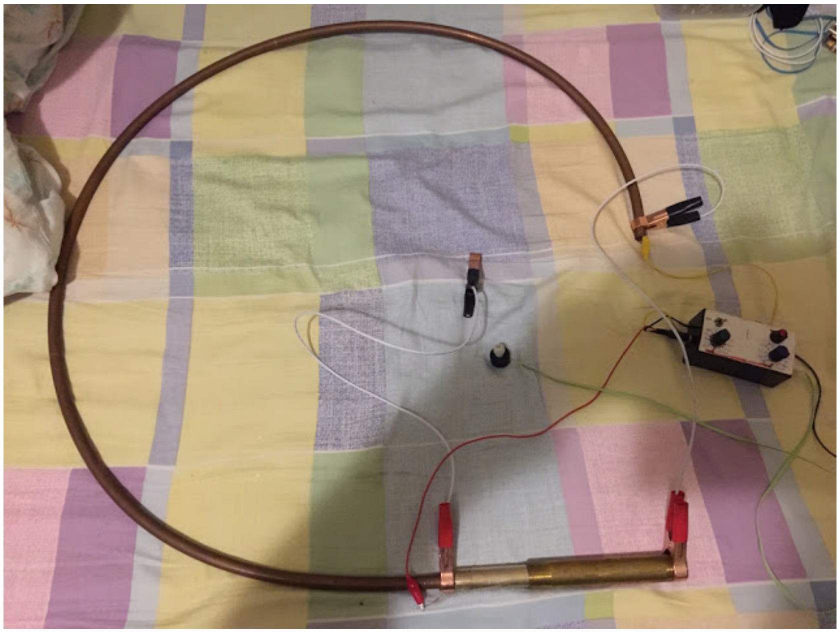
Copper Tube SW radio with a DIY Var Cap.



[http://2.bp.blogspot.com/-p9mh-YtSKY4/VpfAbwcyOsI/AAAAAAAACOk/WLb3ysgAoSw/s1600/IMG_5301.JPG]

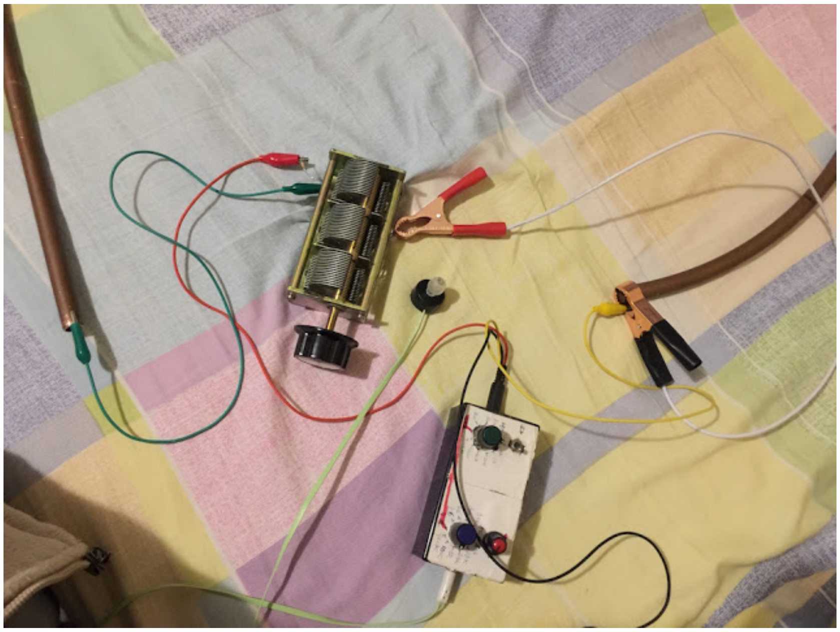
I have built a very simple portable short wave radio that can receive stations without an antenna using half inch or quarter inch copper tubes.

First band the tube into a circle with a diameter close to 1 meter (I used 0.8 meter) but do not close the loop. Leave an openig of around 30 degree to 45 degree.

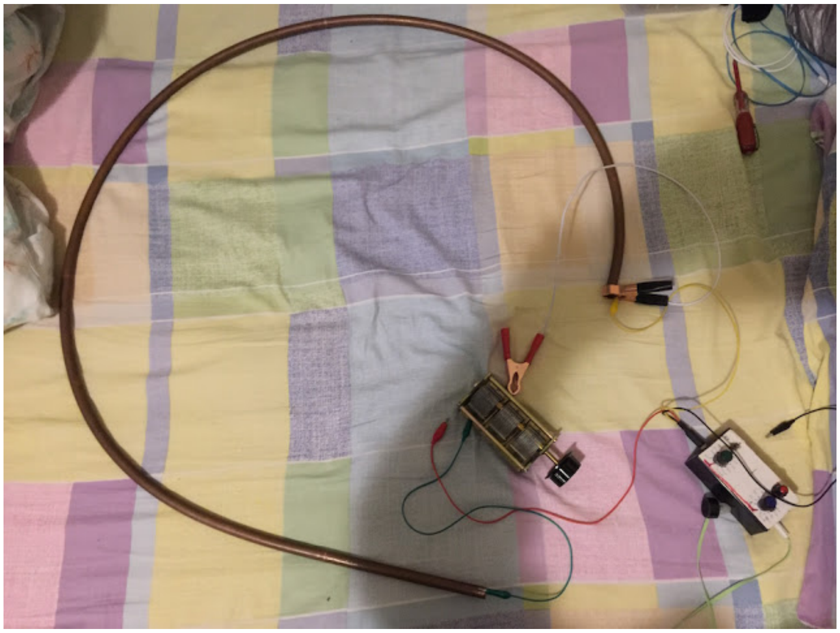
cover the lower SW frequencies) in parallel to both end of the tubes.
Connect one end of the tube to a Crystal radio diode eg 1N34A or 1N60 or even better with 1s106 that I used.
Connect the other end of the diode to a head phone with a impedance that matches that of the output from the diode. Otherwise a transformer will be required to match the impedance. Connect the other end of the tube to the Other end of the headphone. IN the picture below, I used a transformer that step up from 1.5K to 5K to match the impedance of the crystal earphone I am using.
If you are using a magnetic headphone, add a 2000-4000pf capacitor in parallel to it to improve the audio quality.
If you are using a Crystal headphone (aka piezo electric), use a transformer like what I did below for better audio quality, or add a 50k to 1M resistor in parallel to it to sound better.

Placing this horizontally next to my window from my 56/F apartment facing the sea, I can receive SW stations broadcasted from mainland China, Taiwan and other South Asian countries next to Hong Kong.
The loudness will rise and drop within a minute as the SW signal is reflected from afar.

Here are some pictures:



[http://4.bp.blogspot.com/-eOo2a8kKAoo/Vpe73-Jq95I/AAAAAAAACNw/vduQY4dvGME/s1600/IMG_5300.JPG]



[http://1.bp.blogspot.com/-23NdhzZmycQ/Vpe73za4TYI/AAAAAAAACN0/j5X1GFvL0io/s1600/IMG_5299.JPG]

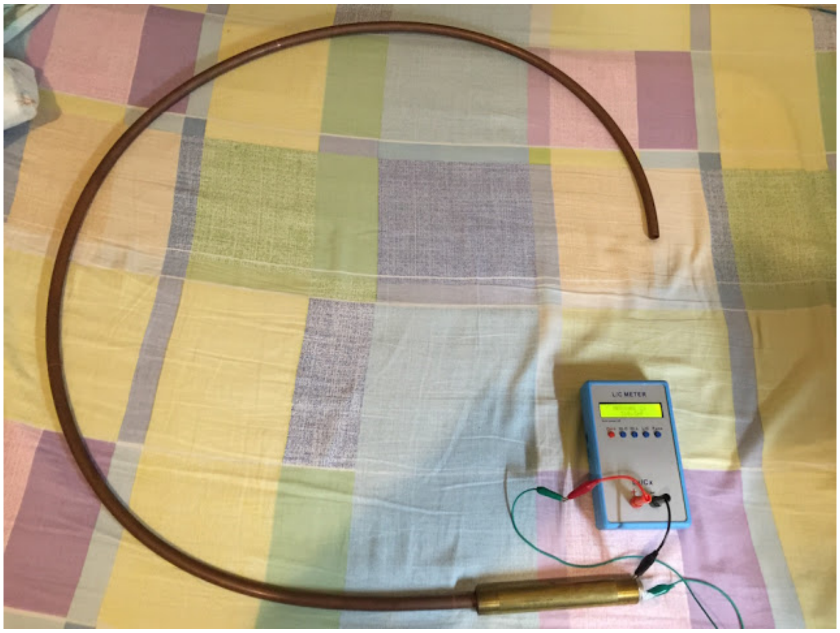
Technically you can DIY your own Var cap also using the copper tube. Instead of banding it to a circle. Band it to form a letter C with a long horizontal tail at the bottom. Then you can place an insulated wider copper tube on top of the tube used for the coil. If the two tubes are close enough together i.e. The gap is less than 0.5 mm, By sliding the outter tube in and out , you can vary the capacitance between them. I guess depending on the surface area and how tightly the two tubes are placed together, the capacitance can vary between 20pf to 500pf. The Q factor will be effected by what is being used as the insulator, Air is best but hard to avoid short circuit. Plastic sheets may work , but will be low Q:
I haven't tried this on SW yet, only on FM.

Here is some diagrams that show you how this will look like.

I mounted another hard straight copper tube covered with plastic sheet (diameter 3/4 Inch) to the original C-Shaped copper tube (diameter 1/2 inch) that forms the coil of the SW Crystal Radio. Because this will increase the surface area and the capacitance . Also the hard straight copper tube has less gap with the wider copper tube (diameter 1 inch), and can slide in and out smoothly.

You can always increase the length of the two copper tubes forming the variable cap by extending the length of these two copper tubes.

You can see from my Capacitance Meter that the DIY Var. Cap can go from 12pf (the outer tube all outside) to 318pf (the outer tube all inside).



[http://3.bp.blogspot.com/-caLYoPy3lUk/VpeZPFAOWyI/AAAAAAAACNA/peDmNZNbK9Q/s1600/IMG_5297.JPG]

Will give it a go when I have some time.

[http://3.bp.blogspot.com/-ZCW4jlaPsiI/VpeZOzTKxVI/AAAAAAAACM4/A-w6q0Ae6CI/s1600/IMG_5296.JPG]

I hooked it up to the diode and the crystal earphone through a transformer 1.5K to 5K to match my crystal earphone.

The loudness of this SW crystal set made using this DIY var. Cap is comparable to that when I used my high Q 500pf Var Cap above. However, tuning is not as stable was the regular Var Cap and you need to adapt to it to learn how to tune. As the copper tube sometime shifts and get loose which alter the Capacitance. With the already varying strength of the SW signal itself, it's even harder to tune and keep the SW station. However, this proof of concept works well.

See how it's hooked up.

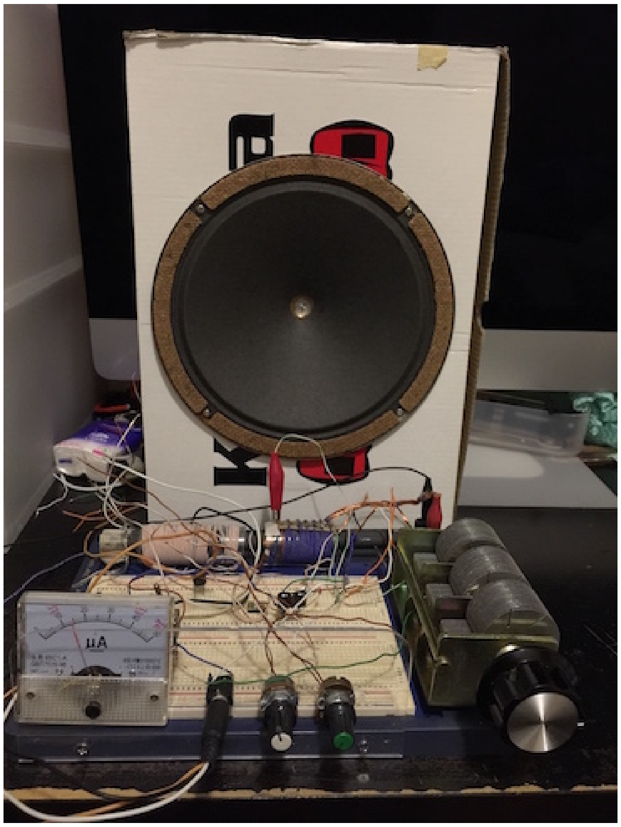
Simple Crystal Radio driving an 8 inch speaker

I experimented with a very simple two stage circuits with a single diode that drive an 8 eight speaker. Though not loud, but it's clearly audible within my quiet room.

Diode: 1ss106.
Distance from the nearest broadcasting station : 15KM.
Antenna 15 meters of 660x0.04 Litz wire drop down from my window 56/F floor, pushed out to 2 meters away from the wall of the building.



[http://2.bp.blogspot.com/-sQZgB03d_ac/Vo-YNdbejHI/AAAAAAAACK8/I8v-PfmhS2Q/s1600/IMG_5234.JPG]

[http://2.bp.blogspot.com/-sQZgB03d_ac/Vo-YNdbejHI/AAAAAAAACK8/I8v-PfmhS2Q/s1600/IMG_5234.JPG]

I can achieve a DC current of 150uA when using this conventional single Diode circuit.

[http://2.bp.blogspot.com/-sQZgB03d_ac/Vo-YNdbejHI/AAAAAAAACK8/I8v-PfmhS2Q/s1600/IMG_5234.JPG]

[http://3.bp.blogspot.com/-mx7IGYUxaOw/Vo-YOMPvw3I/AAAAAAAACLU/09B7iPtbAok/s1600/IMG_5238.JPG]

Then I tried this dual Diode circuit invented by a member of the Chinese Crystal Radio Forum.
I can boost the DC current to 250uA.

SC2-300 foldable headphone

Happy New Year to you.
I decided to give myself a new headphone by converting a faulty monster head phones to crystal radio headphone with two SC2-300 Reed ear pieces.
After fixing the sponge to the headphone, it can be worn comfortably, with good audio effect. The impedance is around 600 ohm when two ear pieces are in series.

How to clean install OSX to a Fusion drive and keep the recovery hard disk function

A. Clean reinstall of OSX.

1. Make sure you back up all your data on the hard disk, as the following step will erase all data.
2. Create the OSX Install USB drive, insert it to the MAC workstation.
3. Since we will operate on the internal boot up drive of the Mac, we need to boot to OSX Install USB drive (See X.)

4. At the menu at the top of the screen, select disk utilities.
5. Highlight the Fusion Drive volume called "Macintosh HD". Click Erase to clean it up.
6. If its successful, then go ahead to install new OSX to this partition as usual.
7. Otherwise if this failed, that means fusion drive has been damaged.
8. Follow onto Be to fix it.

B. Split the Fusion Drive into physical hard disks.

1. Since we will operate on the internal boot up drive of the Mac, assumes that we've already boot up to OSX Install USB drive (See Y.).
2. At the menu at the top of the screen , select Utilities and Terminal.
3. On the terminal screen type:

   ```
   diskutil cs list.
   ```

   You will see something similar to the screen below.

4. Copy the long string after Logical Volume and replace UUID with it in the following command to delete the fusion drive logical volume (aka coreStorage logical volume) :

   ```
   diskutil  cs deletevolume  UUID
   ```

   For example:

   ```
   diskutil cs deletevolume E59B5A99-F8C1-461A-AE54-6EC11B095161
   ```

5. Copy the long string after Logical Volume Group and replace UUID with it in the following command to delete the fusion drive (aka coreStorage) :

   ```
   diskutil  cs delete UUID
   ```

   e.g. `diskutil cs delete E03B3F30-6A1B-4DCD-9E14-5E927BC3F5DC`

6. At this step, the fusion drive has been deleted, and the SSD hardsisk and the mechanical hard disk will be reappearing in diskutil as separate disks.

C. Install a fresh copy of OSX to the SSD hard disk and test that recovery hard disk partition works.

1. Go to diskutil to create a partition called Machintosh HD in the SSD hard disk using all the space there.
2. Do the same with the mechanical hard disk.
3. Follow the usual process to boot from the OSX install USB and install a fresh copy of OSX to the SSD hard disk.
4. This will create the proper boot up partitions, recovery hard disk partitions and the PSX partitions on the SSD hard disk.
5. Once the install is complete, test if OSX can start properly, but no need to go through the initial MAC OSX set up as we'll to scrap this and do the install once again later.
6. We now need to test if the recovery hard disk partition works.
7. Reboot to recovery hard disk (see X - by pressing and holding Command and R at the same time during boot up right after you heard the boot up sound, and only release it a few seconds after you see the apple logo and the progress bar for loading..)
8. This is important to test and make sure the recovery hard disk partition .

D. Recreate the fusion drive

1. Since we will operate on the internal boot up drive of the Mac, we need to boot to OSX Install USB drive (See Y.).
2. At the menu at the top of the screen , select Utilities and Terminal.
3. On the terminal screen type:

You should found that we have a list of physical hard disks only, no logical volume group there yet.

.

4. You will see something similar to the screen below.

5. Look for the largest partition on the SSD hard disk that should be close to the full hard disk size of the SSD (e.g. 121G), and mark the device name, this will usually be something like /dev/disk0s2

6. Look for the largest partition on the mechanical disk that will form the fusion drive with the SSD hard disk. This should be close to the full hard disk size of the mechanical hard disk (e.g. 3TB), and mark the device name, this will usually be something like /dev/disk1s2

7. Now we will create the fusion drive group (a.k.a. logical volume group) by typing this command: **diskutil cs create *lvgName device1 device2***

   For example:

   ```
   diskutil cs create fusiondrive  /dev/disk0s2  /dev/disk1s2
   ```

   You will see something like below showing up on the screen:

   ```
   Creating Core Storage Logical Volume Group

   Switching d isk0s2 to Core Storage

   Switching disk1s2 to Core Storage

   Waiting for Logical Volume Group to appear

   Discovered new Logical Volume Group "DBFEB690-107B-4EA6-905B-2971D10F5B53"

   Core Storage LVG UUID: DBFEB690-107B-4EA6-905B-2971D10F5B53

   Finished CoreStorage operation
   ```

8. Copy down the string after “Discovered new Logical Volume Group” using command + C

9. Next, create the fusion drive partition (a.k.a. logical volume) named “Macintosh HD” by typing this command:

   Diskutil cs createVolume *lvgUUID type name size*

   For example:

   ```
   Diskutil cs createVolume DBFEB690-107B-4EA6-905B-2971D10F5B53 jhfs+ “Macintosh HD” 100%
   ```

10. Go to diskutil to verify that you can see this newly created partition on the list.

11. Test by erasing all data from it.

12. Then you can go ahead to boot to the OSX Install USB drive and install a fresh copy of OSX onto it.

13. This will allow you to keep the recovery hard disk function.

X. How to boot to recover partition

Press and hold the command and R key together immediately after hearing the boot up bell sound.

Only release it 2 seconds after you see the Apple logo on the screen and the progress bar for booting . This will boot to recovery harddisk partition.

Y. How to boot to OSX Install USB

Press and hold the command and Option key together immediately after hearing the boot up bell sound.

Only release it 2 seconds after you see the Apple logo on the screen and This will provide you with a list of boot up disk to choose from, choose the OSX install USB to boot from.

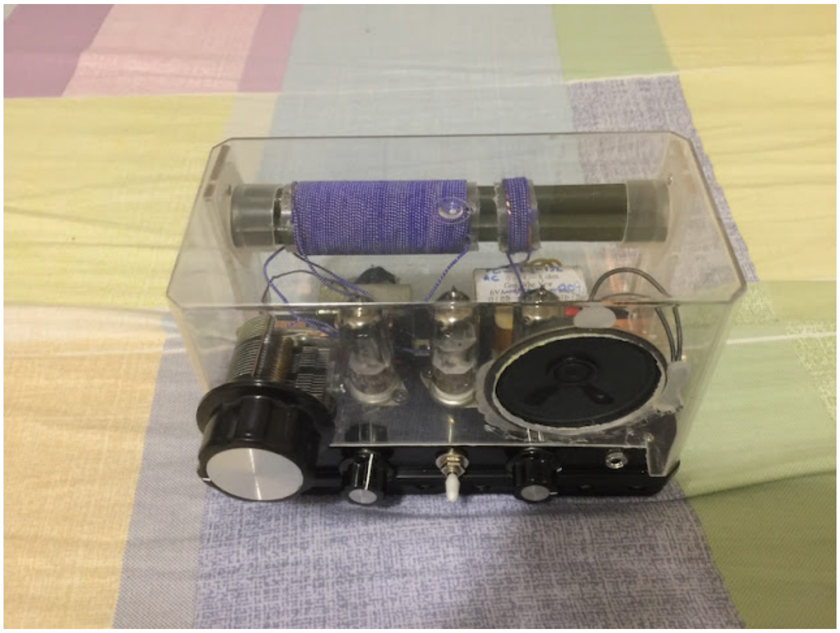
4th October 2015 My first Vacuum Tube Radio - a 26V+1.2V three tubes region.

I built My first Vacuum Tube Radio - a 26V+1.2V three tubes region. radio.



[http://1.bp.blogspot.com/-3Ay3MzXEPZQ/VhEscqD3JMI/AAAAAAAACGU/K0Js38_4W6Y/s1600/IMG_3123.JPG]

I spent 1 month collecting the components. The Chinese Vacuum tubes(1B2, 2P2) can be purchased from the Chinese Taobao shops @ half a USD each. The two transformers are 220V to 6V transformers. Capacitors and resistors are the standard ones.
However, shipping them from China to HK is a bit of headache. There are more and more stringent restrictions for exporting of goods from China. I spent a while finding a courier service that can accept these goods and reship to Hong Kong.
Shipping fees starts from USD 3 per KG. But special goods like these may take USD 6 per KG.

Then I cared too much about how the finished product looks. Spent 2 weeks finding the nice plastic box that is transparent enough.
Finally it all took place in the last few days. The initial circuit was designed by another Chinese hobbyist. The only modification I made is use a bigger coil (litz wire 0.04x220, instead of 0.04x60, and three ferrite rods instead of one), to make it more sensitive.

The negative feed back is somewhat too strong, I had to remove a few turns from the regen coil.

Here is how the finishing produce looks on the video.

Chinese Lantern Crystal Radio

Tomorrow is the mid-Autumn Festival that the Chinese celebrate the festival of the moon.
Children will light up their lanterns to shine through the parks.

What if that lantern can become a crystal radio.
Not only that, the candle light can energise the solar cells from the calculators to bring some small power to drive a regenerative radio to boost the speakers.

I made a lanterns and wind a number of coils to feed to the MOS FET 3DQ.
Next step is to find some solar cells. Those that will work with candle lights.

Here is what I made so far.

Now the crystal radio part is working well. I can listen to most of the local broadcast when I bring the lantern onto the street.
This does attract some people to stop by and listen to my crystal radio.

For the regenerative radio part, I need to find the solar cells to complete the project.

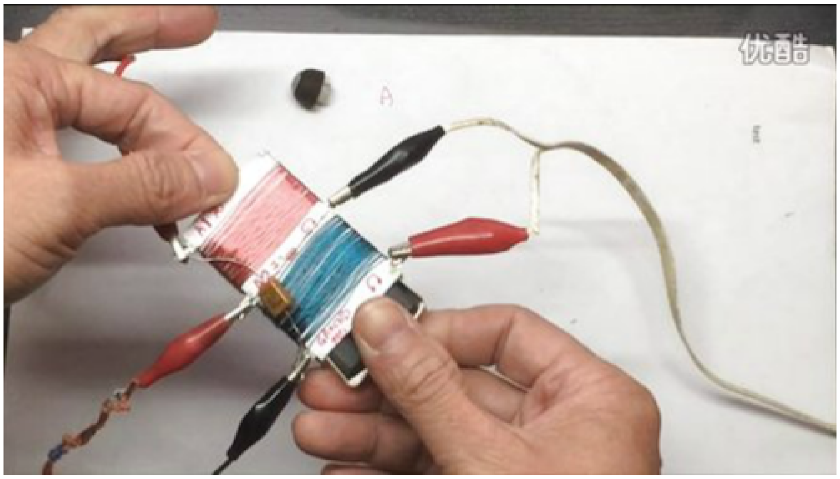
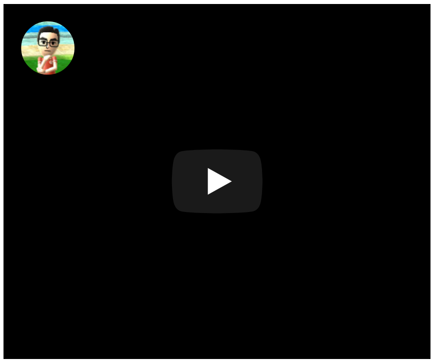
Match box crystal radio



[http://3.bp.blogspot.com/-dmIYfrM-g6U/VehkjPTgnzI/AAAAAAAACDE/xTeA1_Ta93M/s1600/Screen%2BShot%2B2015-08-29%2Bat%2B8.06.00%2Bam.png]

Just made a match box radio using some short ferrite sticks.

Here is the testing video.



The radio is really easy to make. In the bear minimum, you just need the following:
1. A match box measured 60x35x10mm, or make one using cardboards yourself.
2.Magnet wires of AWG 27 or 0.3mm or similar thickness.
3. Any Germanium Diode (e.g. 1N34A, or 1N60, I used 1SS86).
4. Some solder lugs or you can use the paper clip as the connectors for antenna, earth, and earphones.
5. A pair of high impedance earphone or a crystal earbud.
6. A good outdoor antenna of 10 meters or above.
7. A good earth connection, e.g. connect to the water pipe or tap.
8. Fixed capacitor to match the coil for tuning: can be 100pf, 200pf or 300pf or omitted , value will be fixed during testing. Buy a few different fixed capacitor to test with.
9. Fixed capacitor of 2000pf, or can be omitted if your headphone is a crystal earbud.

How to make it:

1. Find a match box of 60x35x10mm,
2. Stick 3 solder lugs at the the left edge of the matchbox
one at the top (A1), one at the middle (A2), one at the bottom (G).
3. Stick 2 solder lugs at the right edge of the matchbox, one at the middle (O1),
one at the bottom (O2).
4. Put two or three small ferrite sticks (8 x 50 mm) inside the match box.
5. Wind the coils:
    L1: tighty wind 38 turns of 0.3 0r 0.4mm Magnet wire starting from the top of the matchbox
    L2: same as L1. wind on the same match box with a 5mm gap between L1 and L2
6. Solder L1, L2 and other components to the solder lugs as shown in the circuit diagram, except the variable capacitor C1. The value need to be tested before soldering that in.
7. Value of fixed capacitor C1 need to be tested to confirm, or can be completely omitted.
8. Fixed capacitor C2 can be omitted if you are using a crystal earbud.

Testing:
Connect the outdoor antenna to A1.
Connect the earth to G.

Connect the headphones to O1 and O2.

Slide the box holding the ferrite sticks inside the matchbox in and out of the matchbox to tune to a station. Try to replace the C1 or remove it to tune to the lowest AM/MW station possible (i..e as close to 500khz as possible).

Next, connect the outdoor antenna to A2.

Try to replace the C1 or remove it to tune to the upper most AM/MW station possible (i..e as close to 1500khz as possible).

Find a C1 value that will allow you to cover the best range, then solder it to the solder slug between A1 and G.

I used a pair of 150 ohm hearing aid earbud, after testing, I found the the performance of the radio is just as fine by omitting C1 and C2. Hence I removed C1 and C2 from my final circuit.

Reception for strong stations is good.

For waker stations that is too close to the strong stations, you have to add a wave trap connected in series between the outdoor antenna and the antenna input of the matchbox ratio to block the strong stations before you can get to the weaker ones.

The wave trap is just another tuning tank make from a coil and a variable capacitor.

Its function is to tune to the strong station that is blocking the weak station, so that signal is blocked from entering your crystal radio so the weaker stations can be heard.

230mm (9") Ferrite Sleeve Loop coil

I came across a post for FSL (Ferrite Sleeve Loop) - FSL Antenna Design Optimization, All-out Experimentation to Determine Weak-Signal Performance Potential By Gary DeBock, Puyallup, WA, USA March 2012 http://www.am-dx.com/antennas/FSL%20Antenna%20Design%20Optimization.htm [http://www.am-dx.com/antennas/FSL%20Antenna%20Design%20Optimization.htm]

I was eager to find out if this is a way to create loops that can have the same sensitivity as a much better loop antenna without ferrite cores. If so, this will be a good way to shrink the loops to make smaller crystal radios with the same or even better sensitivity.

I started following the instruction and twist it a bit to work with what I have at home.

I purchased some cheap ferrite sticks with unknown permeability. Since I cannot find the 10x200mm ones, I purchased the 10x100mm ferrite sticks which is much cheaper (@ 51 RMB for a 100 pieces equivalent to US$8.03). I intend to connect two of these together to make a 10x200mm ferrite sticks. I end up purchasing 200 pieces.
This will allow me to make a FSL with a perimeter of 10x100mm = 1 meter. Diameter of 310mm.

I ended up making one with the diameter of 230mm or 9".

I started with a round plastic container for noodles then wrap multiple layers of foam onto it.
Finally use adhesive tapes to stick the 170 ferrite sticks into position as close enough to one another without any gaps.

Then wrap another layer of thin foam, before winding 20 turns of 0.04x660 litz wires to form the coil for the tuning tank, another 2 turns for MOS FET output.

[http://3.bp.blogspot.com/-Uq1YyrfzxWk/VehalvbPZWI/AAAAAAAAB8s/GAPQMnT44yg/s1600/IMG_2664.JPG]

I was amazed when I hook it up to the air variable capacity and the MOS FET.
Without the ferrite stick, an air loop that size will only produce very tiny output that is just audible.
With the ferrite stick sleeve, the FSLe produced doubled output volume.

Next is to compare this with the other bigger air loops to find out what sized air loops will have the same sensitivity as the FSL.

Testing is not easy as the sensitivity of the reception varies throughout the day.
My place is close to the airport, and every 10 minutes, a plane will literally fly over the top my 60 storey building (may be 1000 meter above), that did have some impact to the reception of crystal radio.
I am also trying to find a measurable unit that can give a true comparison.
For example, I tried measuring the voltage across the terminals of the audio output without the headphone.
I also tried measuring the output current level.
But I found that peak dc voltage, or peak dc current does not mean the loudest audio output.
I do not have a high frequency AC Voltmeter or db meter, so cannot get much out of this.

Next, I tried to use some iPhone software that can measure the audio level in decibels.
This seems to work quite well. I have created a device that can connect the earbud of my 2x150 ohm hearing aid earphone into the mic of the iPhone without much gaps

Then the software will pickup the audio signal form the mic and workout the peak output level.
By comparing the peak output level (db), I will be able to compare the sensitivity of different crystal radios objectively.

There are multiple free db meter software on App Store. I found the measured value of the same audio level from different software varies a bit. In the worst case the variance can be +/50 % when you try to measure the same audio output with different software.

I also made an extensible frame to allow me to adjust the size of the air loop that can be used to compare with the FSL. I hope to find out what size Air loop will have the same sensitivity as the FSL.

Once I prove that FSL is really worth the effort and money, I may upgrade my 9" 230mm diameter FSL to 12" diameter (330mm wide).

Crystal Radio Tests in Tokyo

I just visited Tokyo and brought my umbrella crystal radio for AM reception, and my FM crystal radio for FM reception. Both the AM and FM crystal radios picked up a few local stations with strong signals.

I also visited Akihabara and bought a crystal radio earbud and another 1000 ohm hearing aid like ear bud.

[http://4.bp.blogspot.com/-vq6rMk-1730/U2EiJJWvBUI/AAAAAAAABqQ/H_B8W4quwig/s1600/IMG_6458.JPG]

Do you know that you can listen to radio without battery ? I am holding such a radio in my hand now. It’s all powered by the radio energy.

I am going to share with you how I enjoyed my hobby - making crystal radios. We’ll explore what is a crystal radio, how to make one, and how you can benefit from this hobby.

When I was 10 years old, I was attracted to an article about a magical radio that worked without battery. I saved a few dollars, bought some electronic components and tried to make one. To my disappointment, I could failed. At that time, there is no one to ask or talk to. And I have to drop this hobby.

Last year, a youtube video about a special powerless radio caught my attention. I decided to re-do what I failed to do when I was a kid. I found a forum on the internet hosted in China called crystalradio.cn. After a lot of research and consulting people on the forum, I started making my first Crystal radio. I was overjoyed and could not sleep that night when I heard the the radio broadcast. Today, I have made more than 20 Crystal radios. As small as a pencil, and as big as as a Hula Loop. I even took part in the annual crystal radio DIY contest. My creation got into the second round, and ranked #12 of all the 40 submissions.

Now, let’s see how a Crystal Radio works.

In the old days, Radios were big and expansive. They consume a lot of power as the vacuum tubes inside are big and hot. Then someone replaced the vacuum tubes with much smaller crystals. Not only smaller, these radio can also work without battery. By just harvesting the radio energy, you can listen to a radio broadcast using a head phone. When the signal is exceptionally strong, it can even drive a loud speaker. One other benefit is that as there is no amplification, you can listen to the original sound without distortion.

As technology advanced, crystals were replaced by a electronic component called diodes.

You might now want to know how can you make a crystal radio ?

The simplest crystal radio is made up of 4 components: an antenna, a ground connection, a crystal or diode, and a headphone. This type of radio can only receive a single station as it cannot be tuned.

To add the tuning capacity, you can add a coil, a tuner (or capacitor). The tuner and the coil together allow you to tune to the station that resonant with a certain frequency.

There are two types of crystal radios:

The fixed crystal radios, and the portable crystal radios.

Fixed crystal radios need a long antenna (10 meters or above), and a connection to the ground (your water pipe), to compensate for the smaller coil. The signal will be much stronger than the portable one.

For example, these ones on the table are fixed crystal radios.

I have the tiny crystal radio, a super crystal radio that can receive medium wave and short wave, and the big crystal radio.

Portable crystal radios do away with the long antenna and the ground so you can walk freely with the radio.

To compensate for the lack of a long antenna, you need a bigger coil, at least half a meter in diameter.

Look at these, they are portable crystal radios. I can bring them to the street and listen to the radio.

I have the umbrella crystal radio, the hula loop crystal radio, the hat radio, the filing cabinet radio.

This one is a wearable crystal radio.

One thing I must tell you.

If you try to get on a plane with this on you'll be treated very specially, like a terrorist.

Feel free to try one of these crystal radios.

You can also refer to these links if you are interested to make one.

www.crystalradio.cn

billydiy.blogspot.hk

I find that having a hobby made my life complete. In the past, I just spent my spare time watching TV or films. It's a good thing to relax. However, I find that I enjoy creating things more. Making crystal radio satisfy my inner drive of creativity. It also gave me the stamina to focus on my job.

Do you have a hobby ? If not, I hope you can find one and enjoy it like I do.

百变简易大环矿石收音机

这是一个或多个由超薄的印字机排线当线圈,和3DQ检波器组成的多用途，多效果的无天地线大环矿石收音机。电路是典型的3DQ检波电路，配合270pf 双联可变电容及利用超薄大环的不同配搭，做出多用途，多效果的百变无电源收音机组合。

[http://1.bp.blogspot.com/-4-CZKOQ4tWI/UsfGWB6r4TI/AAAAAAAABjw/alxyiOVAJGs/s1600/IMG_5096.JPG]

[http://www.blogger.com/blogger.g?blogID=2311644141825422235]

大环的主要材料：

用到一种薄薄的印字机排线，在电子令件店有售，，约20元一米，可以做个薄薄的大环，可用作矿石收音机的线圈, 效果还不下于用电线或漆包铜线绕的大环。此排线由1毫文的铜箔

做成. 表面面积大, 能改善趋肤效应带来的影响.铜片与铜片间距1.5毫米, 减少邻近效应,分布电容. 测试后発觉比用电脑排线好.响度加大了。

多效果：利用排线插头交错对接来做出”单股单回路"，或把把每两个排线交错对接，把邻近两个铜箔

一起做个双股线圈来做个"双股单回路"，捕捉多一些电波，增强接收效果。也可做个双回路来增强选择性。可以用一个排线的"单环双回路"或用两个排线的"双环双回路"。

更可做个双环增强回路：用双大环来增强3DQ的能量来增强输出。

多用途：大环矿机：利用排线插座和插头，这大环可打开，可闭合，方便穿进其他支架上，

例如可轻易穿进雨伞骨内做成雨伞矿机。

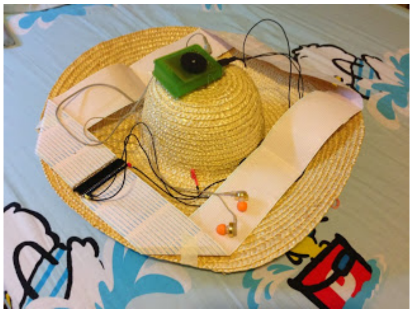
[http://1.bp.blogspot.com/-hoVRDP1ypwE/UsfGdNML12I/AAAAAAAABmY/7ly4VHRLrB8/s1600/IMG_5213.JPG]

[http://4.bp.blogspot.com/-okxpqY2otI8/UsfGdq3GdcI/AAAAAAAABmg/4vOJlGhYmMA/s1600/IMG_5214.JPG]

也可挂在窗户旁，当个室内无天地线矿机，

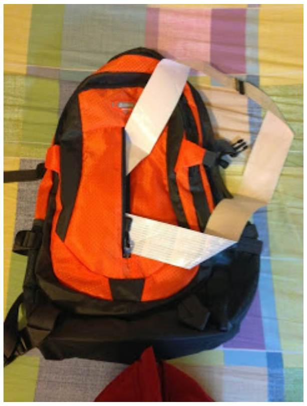
[http://1.bp.blogspot.com/-4-CZKOQ4tWI/UsfGWB6r4TI/AAAAAAAABjw/alxyiOVAJGs/s1600/IMG_5096.JPG]

更可做个小一点的大环，把它折成方形，発挥你的想像力，做出不同用法的无天地线的矿石收音机：
放上帽子边，做个帽子矿机

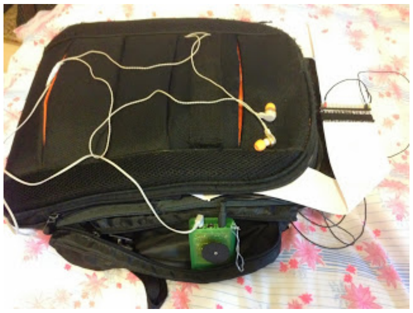


[http://2.bp.blogspot.com/-9Tq6fL7iPQI/UsfGV0m00sI/AAAAAAAABjk/7uRCQu9ebNQ/s1600/IMG_5094.JPG]

放入背包内，做个背包矿机，



[http://1.bp.blogspot.com/-iUyk_0ARW74/UsfGalGseZI/AAAAAAAABlY/Hzsby0MnktE/s1600/IMG_5190.JPG]



[http://2.bp.blogspot.com/-cw-78zBvXj4/UsfGZYJV1zI/AAAAAAAABk4/SRSozHBugWs/s1600/IMG_5106.JPG]

Dynamic Views theme. Powered by Blogger.

[http://1.bp.blogspot.com/-ftaBsa8aHQU/UsfGZkd75-I/AAAAAAAABIA/17rseky6hrE/s1600/IMG_5108.JPG]

放入马甲内，做个马甲矿机，

[http://4.bp.blogspot.com/-TFGyloqWfls/UsfGjcUFGKI/AAAAAAAABos/38-SgwwPOYE/s1600/IMG_5279.JPG]

[http://1.bp.blogspot.com/-5VGLAC9tL8Q/UsfGjxGriKI/AAAAAAAABoo/0PBvhxWPOro/s1600/IMG_5280.JPG]

放入文件匣内，做个文件匣矿机。

[http://4.bp.blogspot.com/-wEhQcrpVGrQ/UsfGaG7tNfI/AAAAAAAABIM/CBjW1VFUloY/s1600/IMG_5109.JPG]

Dynamic Views theme. Powered by Blogger.

[http://4.bp.blogspot.com/-0PJauwFuibA/UsfGadZ9PLI/AAAAAAAABlg/bseYl4fdt_U/s1600/IMG_5110.JPG]

做法：

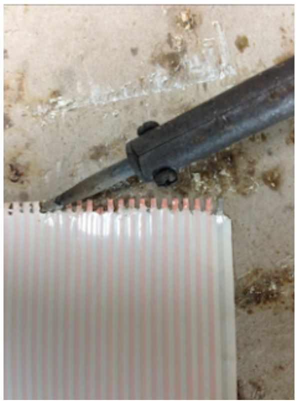
线圈：

找一段印字机用的薄排线(24芯或以), 如买不到,可用电脑彩虹排线代替.

长度是乎用途, 如做雨伞矿机或室内大环用2.8米长的排线.

如做帽子,背包,马甲,文件匣, 用1.2米长的排线.

先用烙铁把排线上的塑料熔丢.露出铜片。再把排线的一端焊接到一个26针排针上，另一端焊接到一个26针排线插坐上再把它焊接到另一个26针排针上。（如用彩虹排线，因彩虹排线的间距离较密，要把两条线当一条线接）。



[http://4.bp.blogspot.com/-28bVQ0Z4G-w/UsfGldoFOpI/AAAAAAAABpI/17PeHg9Kg6E/s1600/Screen+Shot+2013-10-14+at+6.24.37+PM.png]

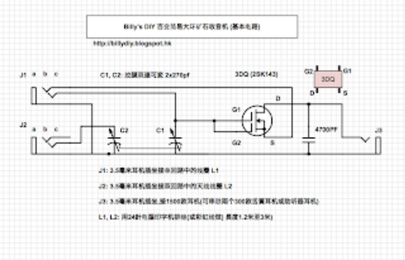
[http://4.bp.blogspot.com/-rCqeleL-Bno/UsfGkZzMcSI/AAAAAAAABo4/M_M9nwKhEHc/s1600/Screen+Shot+2013-10-14+at+6.23.40+PM.png]

[http://3.bp.blogspot.com/-PwM-jbUSDpU/UsfGkKDeJEI/AAAAAAAABpQ/uJRVYsG56Bs/s1600/Screen+Shot+2013-10-14+at+6.22.49+PM.png]

排线插坐和排针是用来把大环的每一圈交错对接和把大环闭合。另一排针是用来做抽头，可匹配阻扩，又可改变波段去收听中波及短波扩播。

电路:



http://billydiy.blogspot.hk
J1 a b c
J2 a b c
C1, C2:
2x270pf
3DQ (2SK143)
G2
G1
3DQ

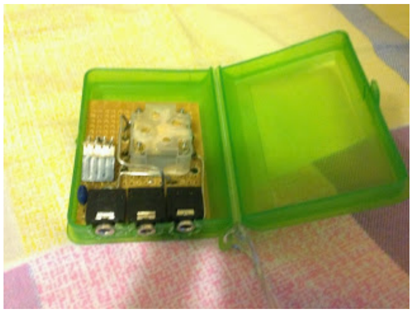
C2
C1
4700PF
J3

[http://4.bp.blogspot.com/-WsEjXrwUFYM/UsfGSe8Ow9I/AAAAAAAABiQ/iq2Ha6hX6jQ/s1600/Circuit+Diagram+1.png]

电路是典型的3DQ检波电路，调谐线圈L1 由插坐J1连接,天线线圈L2 由插坐J2连接.

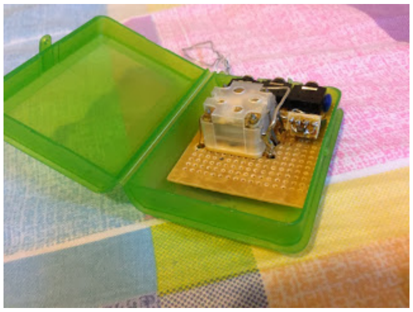
不同的组合可做出不同的电路和效果.

参照电路图,把所有部件包括3dq, 可变电容，线圈插坐J1,J2,耳机插座J3等直接焊接到一小洞洞板上.再装进塑料盒子内。



[http://1.bp.blogspot.com/-ONai7jeqyFU/UsfGgyr5OtI/AAAAAAAABno/juyVz8y3U6E/s1600/IMG_5270.JPG]

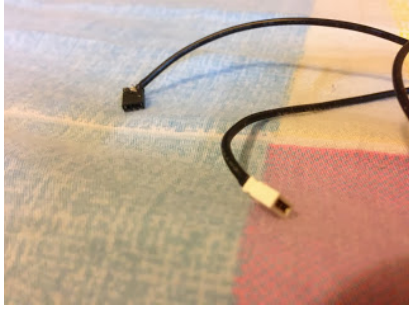
[http://2.bp.blogspot.com/-dMYP6gXJGRw/UsfGhiPXA-I/AAAAAAAABoA/pGgzNwzbSIg/s1600/IMG_5273.JPG]



[http://3.bp.blogspot.com/-E6oa0ClBCcw/UsfGh5cCWKI/AAAAAAAABoM/cs8pJLp_Px8/s1600/IMG_5274.JPG]

把J1,J2接上不同颜色的两脚jumper来插进线圈抽头的排针上。接线插可把两个排针接在一起来做成多种组合:

[http://2.bp.blogspot.com/-GOIpPaOx-CA/UsfGiFSEaxI/AAAAAAAABoI/nYS0bc0ZU2c/s1600/IMG_5275.JPG]



[http://1.bp.blogspot.com/-6NppNDS7Qa8/UsfGibLg0oI/AAAAAAAABoU/bBpXKHJQvW8/s1600/IMG_5276.JPG]

[http://4.bp.blogspot.com/-moXA9ynykz8/UsfGi16d9SI/AAAAAAAABo0/Hv5t8ZJk9mU/s1600/IMG_5277.JPG]

J1-黑色 jumper-接L1线圈地端

J1-红色 jumper-接L1线圈热端

J1-黄色 jumper-接3DQ源极线圈

J2-黑色 jumper-接L2线圈地端

J2-白色 jumper-接L2线圈热端

排线大环的不同组合：

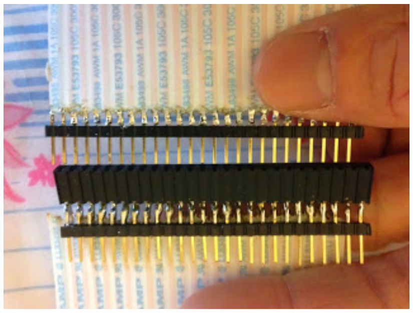
单股单回路:

如做2.8米长的大环,可做阳台上的戸内矿机

如做1.2米长的小大环可用于帽子，背包，马甲，文件匣矿机等：

[http://1.bp.blogspot.com/-4-CZKOQ4tWI/UsfGWB6r4TI/AAAAAAAABjw/alxyiOVAJGs/s1600/IMG_5096.JPG]

把排针交错插进排线插坐上, 例如排针的第一针插进排线插坐的第二洞内, 第二针插进插坐的第三洞内, ...,第廿三针插进插坐的第廿四洞内.



[http://3.bp.blogspot.com/-

再把J1-黄色jumper的其中一脚插到大环的第1匝的排针上

把J1-黑色jumper的其中一脚插到大环的第2匝的排针上

把J1-红色jumper的其中一脚插到大环的第24匝的排针上

这便可把排线的每一线连成大环中的每一匝，做成一个廿四匝的大环.

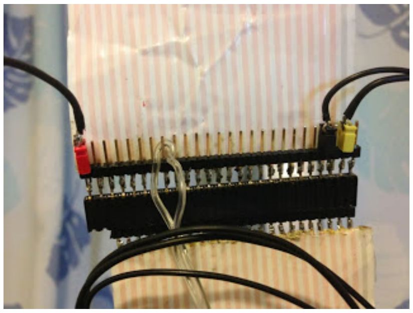
-接L1线圈地端

J1-红色-接L1线圈

再把J1J1-黄色-接3DQ源极线圈

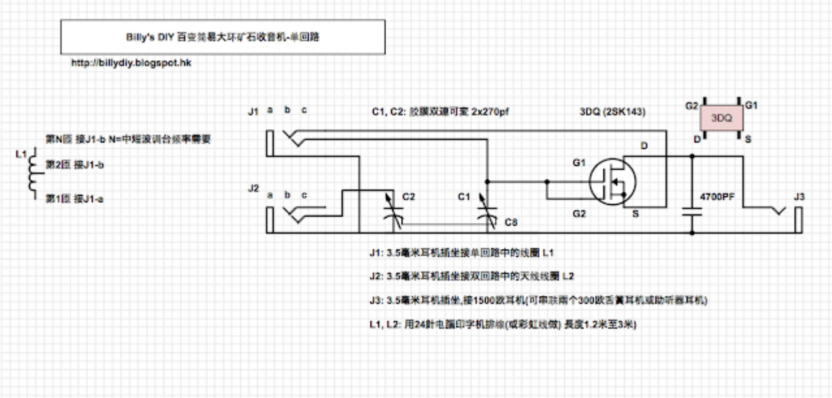
J2-黑色-接L2线圈地端

J2-白色-接L2线圈



[http://3.bp.blogspot.com/-EpvOw2N4JoY/UsfGXaiYQYI/AAAAAAAABkM/nDsYNdrxhm0/s1600/IMG_5101.JPG]

双股单回路:



Billy's DIY 百变简易大环矿石收音机-单回路

再把J1-黄色jumper的两脚插到大环的排针#1和#2上

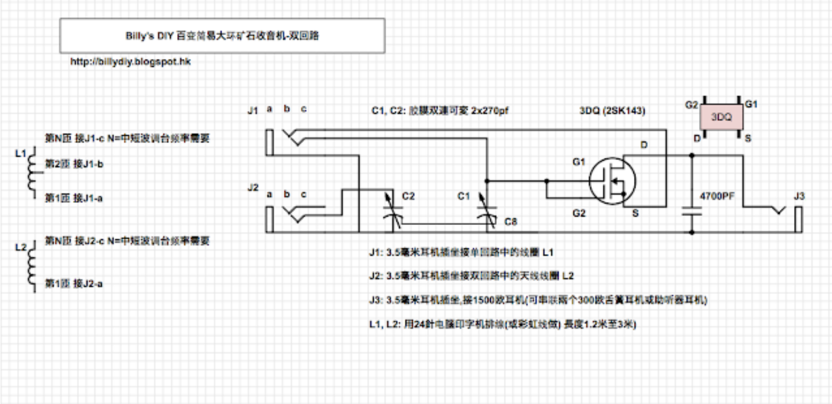
把J1-黑色jumper的的两脚插到大环的排针#3和#4上

把J1-红色jumper的其中一脚插到大环的排针#23上

把J2-白色jumper的其中一脚插到大环的排针#24上

这便可做成两个十二匝的大环, 可做双回路.

双环双回路;



Billy's DIY 百变简易大环矿石收音机-双回路
http://billydiy.blogspot.hk
第N匝 接J1-c N=中短波调台频率需要
L1
第2匝 接J1-b
第1匝 接J1-a
L2
第N匝 接J2-c N=中短波调台频率需要
第1匝 接J2-a
J1 a b c
J2 a b c
C1, C2: 胶膜双連可変 2x270pf
3DQ (2SK143)
G2 G1 3DQ D S
D G1 G2 S
C2 C1 C8
4700PF
J3
J1: 3.5毫米耳机插坐接单回路中的线圈 L1
J2: 3.5毫米耳机插坐接双回路中的天线线圈 L2
J3: 3.5毫米耳机插坐,接1500欧耳机(可串联兩个300欧舌簧耳机或助听器耳机)
L1, L2: 用24針电腦印字机排線(或彩虹线做) 長度1.2米至3米)

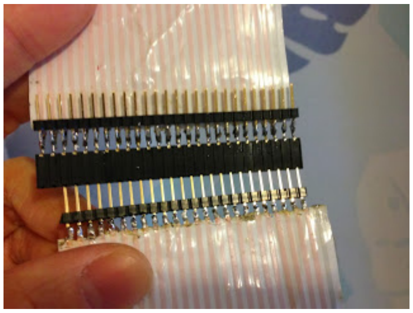
[http://2.bp.blogspot.com/-kWkDFT9avfM/UsfGSr8LSuI/AAAAAAAABic/Gn2z9IR9ZVI/s1600/Circuit+Diagram+3.png]

可用于2.8米长的大环。

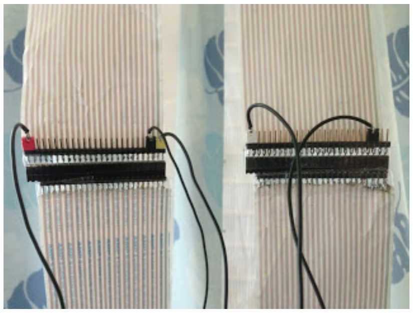
[http://4.bp.blogspot.com/-TD8htYjMlrg/UsfGb995gXI/AAAAAAAABl4/x4NK_mK5whw/s1600/IMG_5205.JPG]

用相同长度的排线做两个大环,大环#1 和大环#2 .

把排针每两针交错插进排线插坐上, 例如排针的第一针插进排线插坐的第三洞内, 第二针插进插坐的第四洞内,第三针插进插坐的第五洞内,第四针插进插坐的第六洞内, ...,第廿三针插进插坐的第廿五洞内, 第廿四针插进插坐的第廿六洞内.



[http://2.bp.blogspot.com/-XOO7T-oHdDs/UsfGXwlc0oI/AAAAAAAABkY/mvXKxZrWp-8/s1600/IMG_5102.JPG]



[http://4.bp.blogspot.com/-O70eMGlpUi0/UsfGe7Fn8pI/AAAAAAAABnA/KWUwo_2p4Ds/s1600/IMG_5246.JPG]

再把J1-黄色jumper的两脚插到大环#1的排针#1 和#2上,使他短路.

把J1-黑色jumper的两脚插到大环#1的排针#3 和#4上,使他短路.

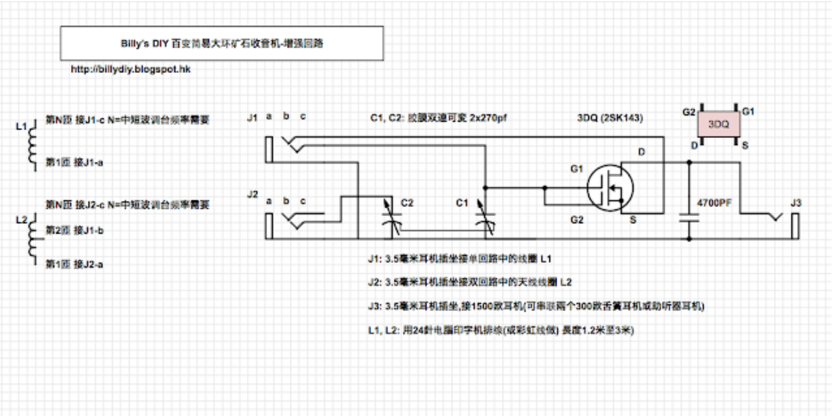
把J1-红色jumper的两脚插到大环#1 的排针#25 和#26上,使他短路.

把J2-黑色jumper的两脚插到大环#2的排针#3 和#4上,使他短路.

把J2-白色jumper的两脚插到大环#2 的排针#25 和#26上,使它短路.

这便可把排线的每一线连成大环中的每一匝, 做一个双骰的十二匝的大环.

双环增强回路:



Billy's DIY 百变简易大环矿石收音机-增强回路

S
3DQ
4700PF
J3
J1: 3.5毫米耳机插坐接单回路中的线圈 L1
J2: 3.5毫米耳机插坐接双回路中的天线线圈 L2
J3: 3.5毫米耳机插坐,接1500欧耳机(可串联两个300欧舌簧耳机或助听器耳机)
L1, L2: 用24針电脑印字机排線(或彩虹线做) 長度1.2米至3米)

[http://1.bp.blogspot.com/-pjmSWnaNgbU/UsfGTPv1JlI/AAAAAAAABik/31Ma7cyL-1c/s1600/Circuit+Diagram+4.png]

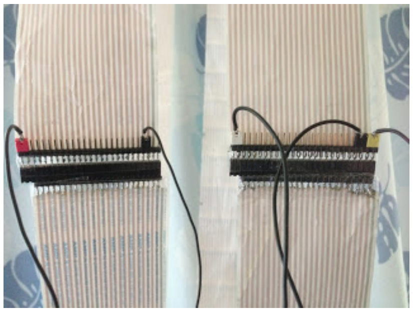
这电路原作者是lq19512003老师的无天地线磁棒矿机,现改良用于大环上.

原理是使用两个距离远到互不干扰的线圈来吸收两倍的无线电能量.

一倍能量用来检波，另一倍提供额外能量给3DQ源极去检波以增强输出.

原理请看h ttp://www.crystalradio.cn/forum.php?mod=viewthread&tid=237270

做法和双环双回路相似,唯一不同是把再把J1-黄色jumper的两脚改插到大环#2的排针#1 和#2上,使他短路.



[http://3.bp.blogspot.com/-vW5KGxW_l8k/UsfGeytnPJI/AAAAAAAABnU/D1z-eTe-NJ8/s1600/IMG_5247.JPG]

矿机调整测试：

把耳机插进耳机插坐. 我用的耳机是两个150欧的助听器耳机串联. 也可用两个300欧的舌簧耳机串联，或接到T725阻矿匹配变压器的2.5千欧端来匹配不同阻扩的耳机。

单回路电路的调整：

调整可变电容调到想听的电台。也可改变红色jumper 接线圈的位置来调到不同的波段。

如要收短波，可把红色jumper 接到线圈的第二匝。 ，

双回路电路的调整：

调整L1和L2的距离使选择性加强，声量也可接受.

调整可变电容调到一个低端的电台。再调整可变电容上的两个微调电容，使响度最大。

再调整可变电容调到一个高端的电台。再调整可变电容上的两个微调电容，使响度最大。重覆以上多一次。

然后可以调到想听的电台。无天地线接收良好，能收数个本地强电台。

双环增强回路电路的调整：

把L1和L2的距离增大使互不干扰

调整可变电容调到一个低端的电台。再调整可变电容上的两个微调电容，使响度最大。

再调整可变电容调到一个高端的电台。再调整可变电容上的两个微调电容，使响度最大。重覆以上多一次。

然后可以调到想听的电台。无天地线接收良好，能收数个本地强电台。

Ball Point Pen Crystal Radio

Ball Point Pen Crystal radio has been featured in 007 movies as a tool for spies. It's been manufactured in the 50's for hobbies. Now it has become a collector item and cost above HK$1000.
Now you can DIY yourself to make one without costing a fortune.
And use it like a Spy. Nobody will know that the crystal radio is hidden inside a ball pen.
Check out this Youtube Video: http://www.youtube.com/watch?v=VsNDIoLwYPs [http://www.youtube.com/watch?

在网上看到圆珠笔矿机，现在已成收藏品，售价 $1000 高得有点过份。
我成功DIY了一个圆珠笔矿机，改良了一些, 比网上的更好：
1，此圆珠笔矿机能用来书写。
2。没有固定连着的线，只在笔顶装了个微型双声道插坐，接耳机，天地线。
要另外做一根转换线来把双声道插分成单声道耳机和天地线。
3，单凭外型，你没法知道这是部矿机。

花了不小时间找合用的圆珠笔及小型磁棒。
数天的试验，用了四枝不同的圆珠笔。
圆珠笔矿机终于做成。

做法：
用吸管做线架，用0.04x14股线绕了两层共25毫文长，7毫米粗的线圈,加了磁棒在最中央位置時最高电感约 480uH.
用个30毫米长4毫米粗的小型磁棒在吸管内作拉杆式调台，
配合180PF固定电容（加上线圈和其他引线产生的约10PF分布定电容）可覆盖大部分中波频率。

有待改良：
因是微型制作，只用了单回路及BAT85二极管检波。
有空可改用3DQ电路，直接焊在贴片上。
也可加绕线圈，改成双回路，可改善现在的轻微串台。
但不知用调感式调台能用双回路吗？
现在的笔芯是用AB胶固定的，不能更换。
可改用固定在小型磁棒上的小圆管来接入笔芯，方便更换

在家中加上天地线后接收良好，能收所有强台。
当天线太强时，有轻微串台，要用天调修正。

今天带了圆珠笔矿机回单位，接上我做的排线间易大环当天线，用电源地线当地线, 能收数个强台。

也吸引了各同工的眼球。
大家都说我是危险人物，什么间谍用品都有。

补充内容
加了了个线圈抽头接检波二极, 选择性好了.
用胶布把笔芯固定现可更换.
加了海绵在拉杆和吸管中间, 防滑防走台.
上了测试及圆珠笔矿机解体的视频.可到20樓看看.

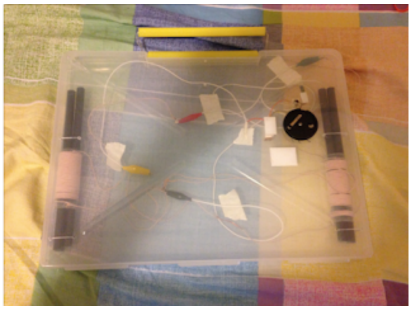
Portable Antenna Free Powder Core Crystal Radio

Dynamic Views theme. Powered by Blogger.



[http://4.bp.blogspot.com/-izv3DGadbUw/UkMCaJssgCI/AAAAAAAABeQ/p39Y_vlN8Jo/s1600/Screen+Shot+2013-09-24+at+11.28.38+PM.png]

Because space is limited, only thin-film variable capacitor can be used.
However, it does not effect the function of the original circuit.

The radio can receive all local stations without an antenna.

When tested in the streets, I attracted some passers-by. They saw a transparent enclosure, and try looking for batteries.
When they can not find it, they asked me why.
I explained to them that a Crystal Radio runs without battery.
They were amazed.

Everybody try to classify crystal radio enthusiasts into types: technical, artistic. I think I might be practical, as I tend to create portable crystal radios that I can listen to on the road.
For example, I can bring this portable radio to the office, stand it up as a normal file, and listen to crystal radio when I have a coffee break.

Why Radio Reception is better at night?

Why Radio Reception is better at night?

In short at night the medium wave, short wave signals can transmit further because the ionospheric layer that bounces these medium wave and short wave signals all over the world gets thicker at night. In the morning when the sun is up, this ionoshperic layer gets thinner and the reflection of radio wave will not be as effective. Due to this effect, radio broadcasting station will lower their transmission power a bit to avoid broadcasting to another country.

According to international regulations, a portion of the radio frequency range of electromagnetic waves is reserved for radio broadcasts.
This is further divided into :

- LW or long wave (frequency range of 150 to 405 kHz) ,
- MW or medium-wave (525 ~ 1605 kHz) ,
- SW or shortwave (2.3 to 26.1 MHz, including 12 m section , see "SW Shortwave Frequency) ,
- FM (band divided from country to country , varies by region) .

SW Shortwave Frequency

UHF	Frequency (MHz)	UHF	Frequency (MHz)
11	25.600-26.100	41	7.100-7.300
13	21.450-27.750	49	5.950-6.200
16	17.700-17.900	60	4.750-5.060
19	15.100-15.450	75	3.900-4.000
25	11.700-11.975	90	3.200-3.400
31	9.500 - 9.775	120	2.300-2.495

Longwave lowest frequency depends mainly on the ground wave transmission, propagation distance, receiver performance is very stable throughout the year . Used mainly in European countries for domestic broadcasting. China has no long-wave radio stations.

Mediumwave is also propagated by terrestrial transmission , similar to that of longwave similar, but influenced by the geographical environment - better over a level surface is better, e.g. fields, plains, sea. worse over the forest, mountains.

transmission. This will also mean that more radio stations from all over the world (local at home, and from the overseas) can be received and jammed into your radio, interfering one another.

SW - shortwave is transmitted mainly by ionospheric effects by multiple reflections spread to thousands of kilometers away , even halfway around the world. This is how the international shortwave radio stations are broadcasted. The ground wave transmission distance for short wave (SW) is limited.
As the short wave gets to your radio through several reflections, the signal strength will be unstable and the volume will fluctuate from time to time. So the high-end shortwave radios have automatic gain control circuit (AGC) to improve the stability of radio reception.
Shortwave reception performances changes with time , season and weather conditions. Average winter sunny day is best, while raindy days in summer nights are the worst.
In addition, your location may be within the quiet zones , namely the area between two reflections. The quiet zone varies by time and frequency. So some radio stations will broadcast using multiple SW frequencies simultaneously and adjust with the change of season.

FM Radio FM mode is generally used for high-fidelity stereo broadcast , the division of the frequency range is complex because it need to jam into the limited spectrum left over from the television broadcasting channels.
FM frequency range is different per country: E.g. Russia from 65.8 to 73 MHz, Japan, from 76 to 90 MHz, China, US and Europe 88 ~ 108 ~ 104 MHz or 88 MHz. FM signal and the television broadcast signal is propagated only on a straight line , so the FM program can only be received in the region locally. The general maximum distance does not exceed 100 km. The reception is very stable as the signal is broadcasted over a straight line to a limited geographical location all under good control. Because the propagation distance is small, each region may be from a broadcast network , the same band can be reused.

In summary, at night the medium wave, short wave signals can transmit further because the ionospheric layer that bounces these medium wave and short wave signals all over the world gets thicker at night. In the morning when the sun is up, this ionoshperic layer gets thinner and the reflection of radio wave will not be as effective. Due to this effect, radio broadcasting station will lower their transmission power a bit to avoid broadcasting to another country.

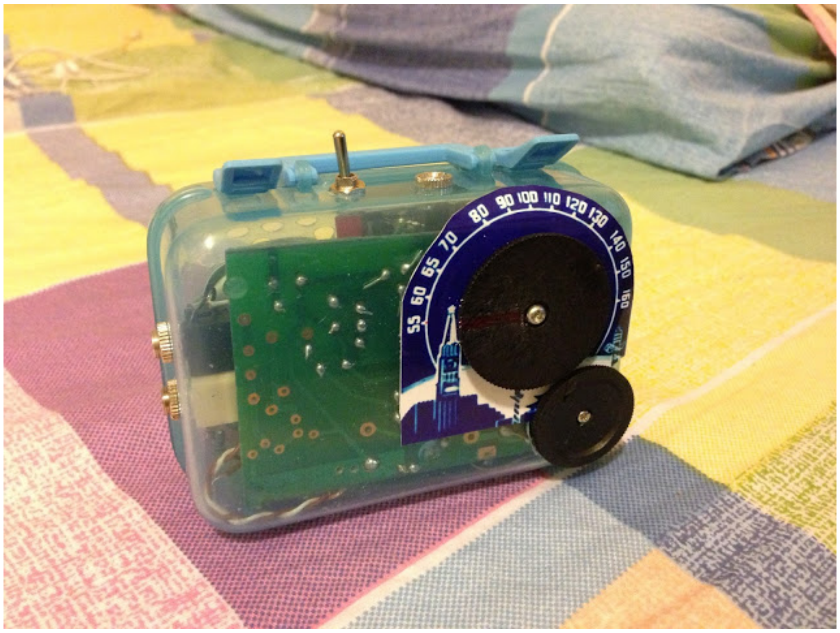
TA7642+LM386 regeneration radio

TA7642 (aka MK484) is an IC for AM and SW radio. It has all the circuit you need to make a regeneration radio of Auto Gain Control. Only need to add the LM386 to amplify the sound to drive the speaker.



[http://2.bp.blogspot.com/-zGJ2RSo65fo/UiNN5M-CkzI/AAAAAAAABc4/H2uxz_ni0QQ/s1600/IMG_3457.JPG]

I have ordered the circuit board from the Taobao shop and changed the circuit a bit to double it up as an amplifier for my other crystal radios.
I also added a socket to insert an external radio coil, so I can connect my 1 meter diameter SW radio loop coil (made of

9mm copper tube, see last photo below), and change it to an Short Wave Radio.

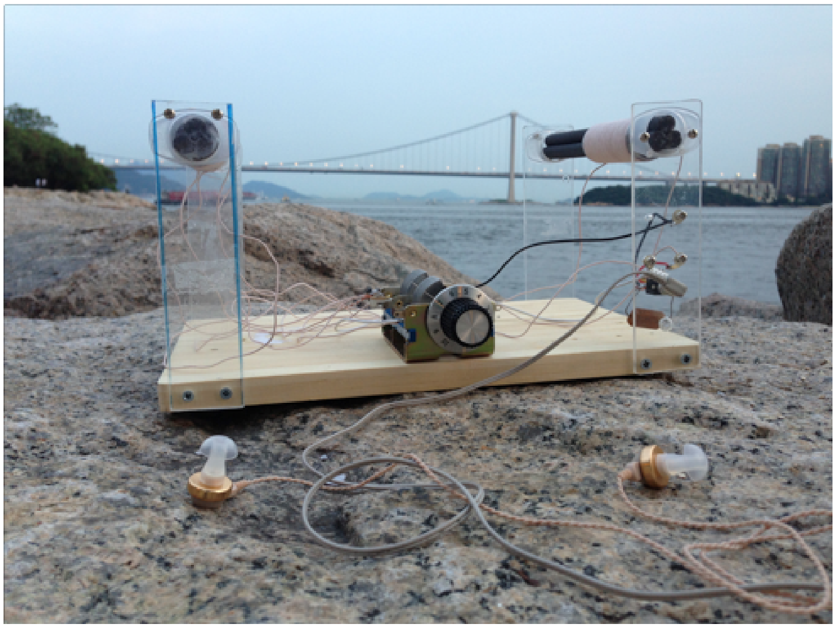
Antenna-Free Powder-Core-Coil Crystal Radio

You can now listen to an antenna free crystal radio on the street without carrying a big loop radio around.



[http://4.bp.blogspot.com/-Dw4S-jKjN3s/UiAdAxqeEQI/AAAAAAAABYg/Ao6hPtYDh9E/s1600/Screen+Shot+2013-08-

[http://2.bp.blogspot.com/-D_R-juaEpdQ/UiAdGlH42NI/AAAAAAAABZE/pMNHKBBhy3I/s1600/Screen+Shot+2013-08-30+at+9.58.34+AM.png]

Checkout this youtube video for the testing of this radio [http://youtu.be/kRPyu5_Lh-8] :

Without worrying about sharing the same antenna, this one doubles up the radio wave energy using two separate powder core coils .
L1 to receive the original radio signal and turn that into audio thru the MOS FET (G1/G2 & D).
L3 to get a second copy of the radio signal, pump that thru L2 to energize the MOS FET (S).
All coils are wound on a 25mm diameter PVC tube (or a 30ml Syringe) using Liz wire (0.04mm x 270).
L2 & L3 shared the same powder core (Insert 3 powder rods into the PVC tube each of 8mm (D) and 180mm (L) .
L1 is on its own powder core same size as L2 & L3, but must be at least 300mm away from that of L2 & L3.
L1, L2 & L3 must be at least 300mm away from any other metallic components I(i.e. VC) to have the best effect.
L1 & L3 : 55 turns (60 turns if your variable capacitor is 270PF only), L2: 5 Turns.
L1 & L3 : 55 turns (60 turns if your variable capacitor is 270PF only), L2: 5 Turns.

Position both coil L1 and L3 to the middle of the Powder rod, and L3 immediately follows L3.. Then perform the following adjustments:

1. Tune to a radio station of the lowest frequency, e.g. 567khz, then adjust the position of L1,L2,L3 to get the best reception .
2. Tune to a radio station of the highest frequency, e.g. 1400khz, then adjust C3 to get the best reception.
3. Repeat 1 & 2 a few times until you get best reception for both the low end and high end stations

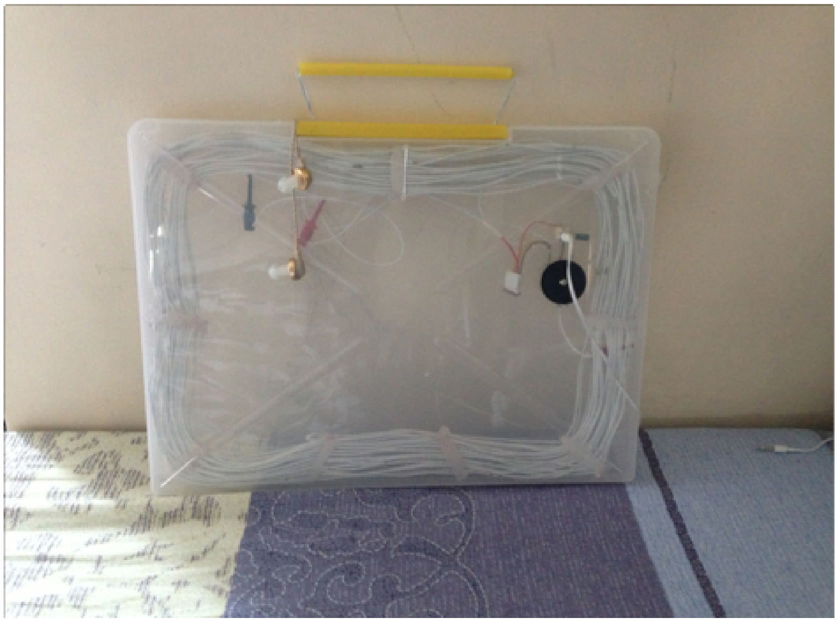
Portable Document Tray Crystal Radio

Portable Document Tray Crystal Radio



[http://1.bp.blogspot.com/-3mB9i-V3mkA/UambfizR cI/AAAAAAAABXg/nbDIcv9xeFY/s1600/Screen+Shot+2013-08-

13+at+10.03.46+AM.png]

Make a battery-free crystal radio using a filing box.
Place it next to the window to listen to radio stations without battery.
You can also put it inside your briefcase or backpack and listen to crystal radio while you are traveling.

How to make it:

Find a plastic filing box, the bigger the better. The one I got is B4 (380mmx280mm). It'll be even better if you can find an A3 filing box.
Then wound a radio coil inside following the instructions below:

Make a card board coil mod same size as the filing box. Cut 9 slots 40mm deep, 10 mm wide at the edge of the boards. The number of slots must odd, as we need the wires to go above and below to create a spider web effect. This will be better for the radio signal reception.

Get some regular electric wires size around SWG22. Wound 26 turns above and below the slots as shown in the video. How to wind a spiderweb radio coil. [http://www.youtube.com/watch?v=GHq7fVLr9OI]

Then fix the wire in place, by either ting each slot up with fishing wire or super glue or rubber gun.
Drill some holes into the back of the filing box so you can tie the radio coil up.

Drill more holes to hold the crystal radio components.

We will need a MOS FET called (2SK143, or 3DQ), a plastic variable capacitor that goes from 20pf to 270pf as you adjust the dial.
A 3.5mm headphone socket.
Two hearing aid headphones (300 Ohm) connected in series to a mono 3.5mm headphone jack.

This radio operates without antenna nor ground.
You can receive several local radio stations, and the sound is loud.

You can also turn it into a briefcase crystal radio by adding a handle.

10th August 2013

You need a crystal earphone to listen to the battery free crystal radio.
I've been making the crystal earphone myself as it's hard to buy in Asia.
A friend of mine helped me buy a few crystal earphone from US (Ceramic Earphone US $ 3.5).
I compared the factory made crystal earphone (left0 with the ones I made myself (right).

The result: the homemade crystal earphone won!

The factory made one is not as loud as the homemade one, it's about 30% softer. The homemade one has better audio quality, with a much richer base than the factory made one.

If you also want to own a look at my other posts:

gift box AM FM solar powered regeneration crystal radio

I designed a small gift box AM FM solar powered regeneration crystal radio.All wiring done with silver-plated wire to allow a variety of functions and AM FM coils to be placed in a 120mmx90mmx40mm small box.Appears to be an ordinary wooden box, yet opens into a crystal radio.

This cute gift box crystal radio can be a gift for the children. Promote interest in crystal radio. The machine can operate with or without power.

AM circuit includes 100mm ferrite rod with a coil wound using 0.05x120 lz wire.

What is AM and FM ?

What is AM and FM ? Are AM and MW the same thing ?

Audible Frequency

standard range of audible frequencies [https://en.wikipedia.org/wiki/Hearing_range] for humans is 20 to 20,000 Hz,
However, the audible frequency ,e.g. the music , is not efficient to be broadcasted over radio wave nor can travel very far.
To solve the problem, we will need something to carrier the music. This something is called the Carrier wave.
Then we need to use a method to put the music onto the carrier wave and produce the ultimate radio wave that can be broadcasted. This method is called modulation.

Common layman terms that are mostly right , but not always right.

AM and MW usually means the same thing in layman terms. It means the broadcast radio transmitted at the frequency within the medium wave (MW) frequency range (or Band) -(540Khz to 1650khz) and modulated using AM (Amplitude Modulation).

MW is a subset of a standard term called MF - Medium Frequency) that describe frequency range of 300Khz to 3000Khz. See table below).

Amplitude modulation means the carrier frequency is fixed all the time, but the amplitude of the carrier wave will vary according to the the wave of the music being carried. i.e. The amplitude is modulated by the music.

FM and ultra short wave usually means the same thing in layman terms. It means the broadcast radio transmitted at the frequency within the ultra short wave frequency range - 88Mhz to 108Mhz) and modulated using FM (Frequency Modulation).

Ultra short wave is a subset of a standard term called VHF - Very High Frequency) that describe frequency range of 30 Mhz to 300Mhz. See table below).

See table below.

Frequency modulation means the amplitude of the carrier wave is fixed all the time, but the frequency of the carrier wave will vary back and forth by a factor from the central frequency of the radio station you tuned into . This variation of frequency is according to the the wave of the music being carried. I.e. The frequency is modulated by the music.

Aviation communication uses AM but at the frequency range just above the FM radio ?

Pilots communicates with the airports at the Vivil aviation band - VHF 108Mhz to 136 MHz.
However, the voice of the pilots are put on the carrier wave using Amplitude Modulation (AM).
This is a good example to show that FM radio band, will sometimes be broadcasted using AM.

Types of modulation

AM

is the name given to the method to put an audio signal (voice/music) onto the radio wave, called
Amplitude Modulation - fixed frequency with the amplitude of the wave shifting according to the volume of the music.

1. A standard radio wave of a fixed frequency (of that of the radio station) is first broadcasted. If no one music is played, the standard radio wave will have same amplitude (volume) all along, and you will hear silence from the radio receiver.
When the music starts playing and feed to the transmitter, then depending on the volume of the audio signal (voice/music), the radio wave will go up or down in amplitude (or volume).

This ups and downs in amplitude (volume is then translated by your radio receiver into audible sound coming form your headphone.

FM

is the name given to the method to put an audio signal (voice/music) onto the radio wave, called
Frequency Modulation - fixed amplitude with the frequency of the wave shifting according to the volume of the music.

Like AM, 1. a standard radio wave of a base frequency (of that of the radio station) is first broadcasted. If no one music is played, the standard radio wave will have same frequency all along, and you will hear silence from the radio receiver.
When the music starts playing and feed to the transmitter, then depending on the volume of the audio signal (voice/music), the radio wave will shifts left and right in frequency within the frequency spectrum allocated to that radio station. E.g. RTHK2 may be broadcasting at 94.8Mhz +/-0.05Mhz. So, if music volume is low, it'll shift to 94.75Mhz, if music volume is high, it'll shift to 94.85Mhz.

What is LW, MW, SW1, SW2, Ultra SW ?

LW, MW, SW and FM are all descriptions of the frequency range used in radio broadcasting.

LW is short for Long Wave with a frequency range from 100Khz to 500Khz. It is a subset of the standard wireless terms we called LF (low frequency).
MW is short for Medium Wave with a frequency range from 0.5Mhz (500Khz) to 1.7 Mhz (1700Khz). i.e. MF (medium frequency)

SW is for Short wave, i.e. HF (high frequency)
SW1 is short for Short Wave One with a frequency range from 5Mhz to 10 Mhz.
SW2 is short for Short Wave Two with a frequency range from 11Mhz to 19 Mhz.

Ultra Shortwave is the range where FM radios are broadcasted. 70Mhz to 120Mhz.
i.e. VHF (very high frequency).

Band name	A	I	F	Example Uses

	breviation	U band number	equency and Wavelength	
Extremely low frequency [https://en.wikipedia.org/wiki/Extremely_low_frequency]	ELF	1	3–30 Hz 100,000–10,000 km	Communication with submarines [https://en.wikipedia.org/wiki/Communication_with_submarines]
Super low frequency [https://en.wikipedia.org/wiki/Super_low_frequency]	SLF	2	30–300 Hz 10,000–1,000 km	Communication with submarines
Ultra low frequency [https://en.wikipedia.org/wiki/Ultra_low_frequency]	ULF	3	300–3,000	Submarine communication, communication within mines [https://en.wikipedia.org/wiki/Through_the_earth_mine_communications]

			Hz 1,000–100 km	
Very low frequency [https://en.wikipedia.org/wiki/Very_low_frequency]	VLF	4	3–30 kHz 100–10 km	Navigation [https://en.wikipedia.org/wiki/Radio_navigation] , time signals [https://en.wikipedia.org/wiki/Radio_clock] , submarine communication, wireless heart rate monitors [https://en.wikipedia.org/wiki/Heart_rate_monitor] , geophysics [https://en.wikipedia.org/wiki/Geophysics]
Low frequency [https://en.wikipedia.org/wiki/Low_frequency]	LF (LW)	5	30–300 kHz 10–1 km	Navigation, time signals [https://en.wikipedia.org/wiki/Radio_clock] , AM longwave [https://en.wikipedia.org/wiki/Longwave] broadcasting (Europe and parts of Asia), RFID [https://en.wikipedia.org/wiki/RFID] , amateur radio [https://en.wikipedia.org/wiki/Amateur_radio]
Medium frequency [https://en.wikipedia.org/wiki/Medium_frequency]	MF (MW "AM radio")	6	300–3,000 kHz 1,000–100 m	AM [https://en.wikipedia.org/wiki/AM_broadcasting] (medium-wave) broadcasts, amateur radio, avalanche beacons [https://en.wikipedia.org/wiki/Avalanche_transceiver]

Sun bath for my crystal radios

Last Sunday I went to the gold coast beach in Hong Kong.
It's quite close to the FM radio transmission station.
You can listen to the FM radio from the battery free FM crystal radio just by raising the antenna.

I've also took this chance to take a good photo of all the different types of crystal radios I made.

Wearable Battery-Free Jacket Crystal Radio

Build an always wearable Crystal Radio by winding a coil at the inner linings of your jacket.
You can walk with it, run with it, ride bicycle with it and continue to listen to radio.

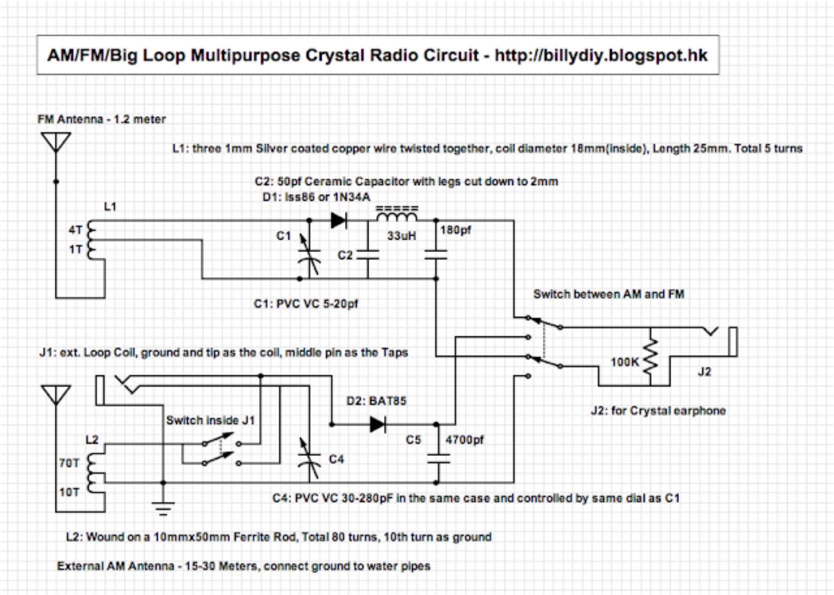
AM/FM/Loop Crystal Radio

[http://3.bp.blogspot.com/-W5MoCILOqOU/Uc2WU1CTbbI/AAAAAAAABNA/hH64_FNxMpo/s436/Screen+Shot+2013-06-23+at+12.06.23+PM.png]

Build a multifunction battery free crystal radio to listen to either AM or FM radio.
You can also use the same radio to connect to a bigger loop coil to get stronger signal for the AM radio instead of relying on the smaller AM coil inside the radio.

Parts you will need:
A Diode that works in high frequency (200Mhz or above, e.g. AA112, 1N34A, 1N48, Iss86 or Iss106.
A Diode that work in AM frequency e.g 1N34A, 1N60, BAT85.
A quadruple PVC Variable capacitor with one end for 2x 20pf, the other end for 2x 140pf.
50pf and 180pf fixed ceramic capacitor
100K 1/4W resistor
33uH Choke coil.
AM radio coil - ferrite rod
3.5mm mono headphone jack
3.5mm stereo headphone jack with internal switches (for selecting whether to use the external big loop or the internal coil for AM.
A 2 by 3 switch to select AM or FM.
A high impedance 4K Ohm earphone or a crystal earphone.

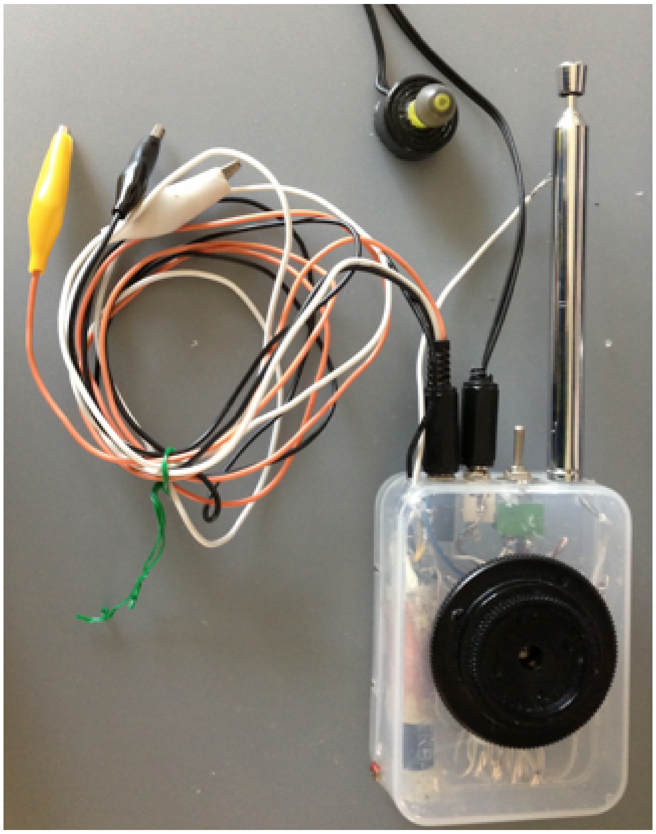


AM/FM/Big Loop Multipurpose Crystal Radio Circuit - http://billydiy.blogspot.hk
FM Antenna - 1.2 meter
L1: three 1mm Silver coated copper wire twisted together, coil diameter 18mm(inside), Length 25mm. Total 5 turns
C2: 50pf Ceramic Capacitor with legs cut down to 2mm
D1: Iss86 or 1N34A
L1
4T
1T
C1
C2
33uH
180pf
C1: PVC VC 5-20pf
Switch between AM and FM
J1: ext. Loop Coil, ground and tip as the coil, middle pin as the Taps
100K
J2
D2: BAT85
J2: for Crystal earphone
Switch inside J1
L2
70T
10T
C5
4700pf
C4
C4: PVC VC 30-280pF in the same case and controlled by same dial as C1
L2: Wound on a 10mmx50mm Ferrite Rod, Total 80 turns, 10th turn as ground
External AM Antenna - 15-30 Meters, connect ground to water pipes

[http://2.bp.blogspot.com/--ZAhsy2SRko/Uc2WUu2Gz6I/AAAAAAAABM8/czIHQF1iPzI/s855/Screen+Shot+2013-06-23+at+11.22.21+AM.png]

Dynamic Views theme. Powered by Blogger.

To connect to external Loop coil for AM reception instead of using the internal AM coil, connect 3-color crocodile camp to the 3.5mm Stereo jack - white for the tuning, black for ground, yellow for the decoder diode.



[http://3.bp.blogspot.com/-df0Gv1TiXME/Uc2WTw3VL8I/AAAAAAAABMs/hJaPbNYh4uQ/s415/Screen+Shot+2013-06-23+at+1.19.26+PM.png]

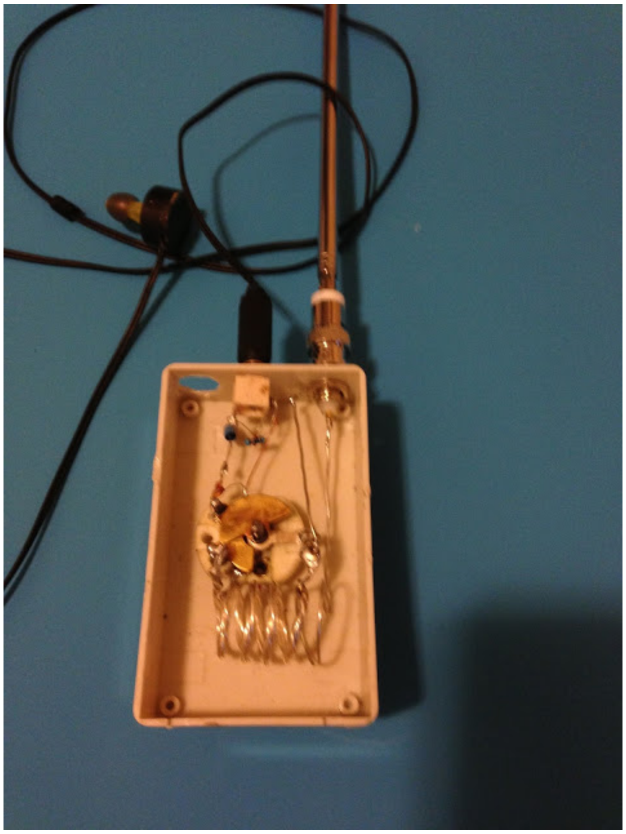
FM Crystal Radio

Build a battery free FM crystal radio using 1mm silver plated copper wire

[http://2.bp.blogspot.com/-LyTLmJ0D5ao/Uc2SwAO-02I/AAAAAAAABL4/jkHYmvlimcE/s1600/IMG_2535.JPG]

This FM radio runs without battery and you can listen to FM radio by just placing this close to your window.
If reception is not good, you can attach an external FM antenna (or with antenna amplifier), instead of using the 1.2M radio antenna.

Parts you will need:
A Diode that works in high frequency (200Mhz or above, e.g. AA112, 1N34A, 1N48, Iss86 or Iss106.
A 0-12 pf AIR Variable capacitor - you can get a 0-22pf one, then remove all the copper plates and leave just 4.
50pf and 180pf fixed ceramic capacitor
100K 1/4W resistor
33uH Choke coil.
Silver platted copper wire 1mm diameter
1.2meter radio antenna.
3.5mm mini headphone jack
A high impedance 4K Ohm earphone or a crystal earphone.



[http://3.bp.blogspot.com/-NhzpbldzMyU/Uc2SwLCh3LI/AAAAAAAABL8/J7ym0UWhqqk/s1600/IMG_2536.JPG]

Battery Free Loop FM Crystal Radio

Battery Free Loop FM Radio using an 8-mm diameter copper tube.

This FM radio runs without battery and you can listen to FM radio by just placing this close to your window.
If reception is not good, you can attach an external FM antenna (or with antenna amplifier), to the Loop at the point 1/3 of the loop close to the ground.

Parts you will need:
A Diode that works in high frequency (200Mhz or above, e.g. AA112, 1N34A, 1N48, Iss86 or Iss106.
A 0-12 pf AIR Variable capacitor - you can get a 0-22pf one, then remove all the copper plates and leave just 4.
50pf and 180pf fixed ceramic capacitor
100K 1/4W resistor
33uH Choke coil.
3.5mm mini headphone jack
A high impedance 4K Ohm earphone or a crystal earphone.
Some wires.

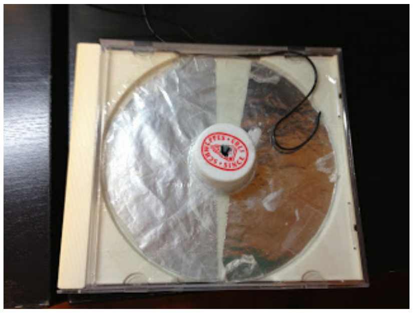
Make a variable capacitor out of a CD case and a CD

Make a variable capacitor out of a CD and a CD case.



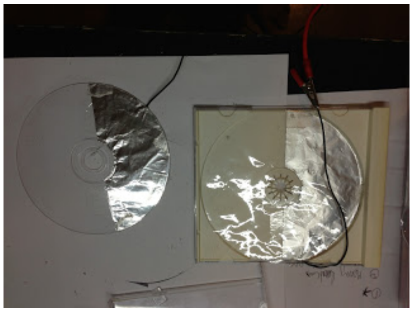
[http://2.bp.blogspot.com/-fjTMYdnkRSQ/UZgpVKlgr8I/AAAAAAAABKY/BgEkJoISM4M/s1600/IMG_1865.jpg]

Use CD that is transparent (without the magnetic/metal coating.

[http://1.bp.blogspot.com/-Izm_2BkhKVU/UZgmsAytz2I/AAAAAAAABI4/Rm2qMOOijil/s1600/IMG_1855.JPG]

Cut a circular piece of aluminium paper foil (even better if you can use copper foil), a little bit smaller than the size of the CD. Then cut it in half.
Paste one half of the aluminium paper foil onto the bottom of the CD case.

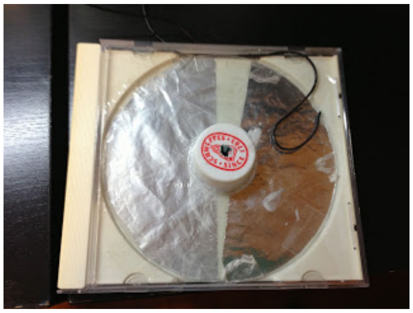
Paste the other half onto one side of the CD.
Tape wires onto the aluminium paper.



[http://4.bp.blogspot.com/-AhSF6NvwA5A/UZgmsA2llhI/AAAAAAAABI8/lm5waOADzDU/s1600/IMG_1858.JPG]

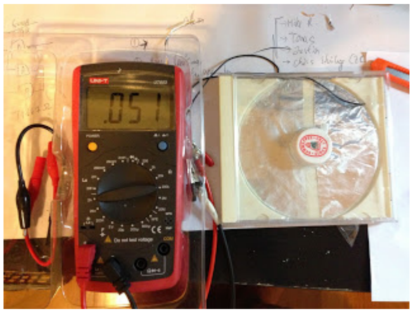
Cut a circular piece of thin plastic film (as soon as you can find, yet strong enough to withstand the pressure and still insulate the aluminium foil from one another).
Paste the plastic film onto the bottom of the CD case on directly top of the aluminium paper foil.

Put the CD on top with aluminium paper facing down).
Paste a plastic bottle caps on the centre of CD to function as the knob to turn the variable capacitor.
In front of the CD case, open a hole slightly larger than the plastic caps.
on the CD case. Close the CD case.

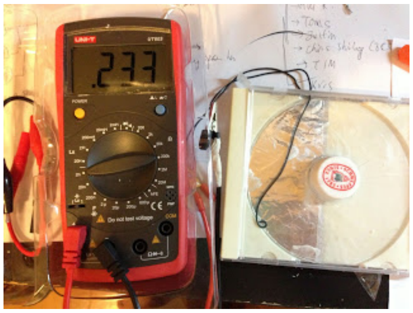


[http://1.bp.blogspot.com/-oNHHtxWGxn4/UZgqEgChk6I/AAAAAAAABKk/8JVTjJD8ADg/s1600/IMG_1865.jpg]

Test the CD Variable Capacitor using a Capacitance Meter. Mine can have a capacitance from 51pf to 233pf when turning the knob. You may be able to do better by pressing the CD and the CD case firmer together. Or replace the aluminium foil with copper foil.



[http://4.bp.blogspot.com/-5bFY1MxzH1w/UZgonsTLu7I/AAAAAAAABKI/X4ureG3Esss/s1600/IMG_1860.jpg]



[http://4.bp.blogspot.com/-ocCLqbtDhVQ/UZgon6TKWGI/AAAAAAAABKM/9nSD9nMt6a4/s1600/IMG_1862.jpg]

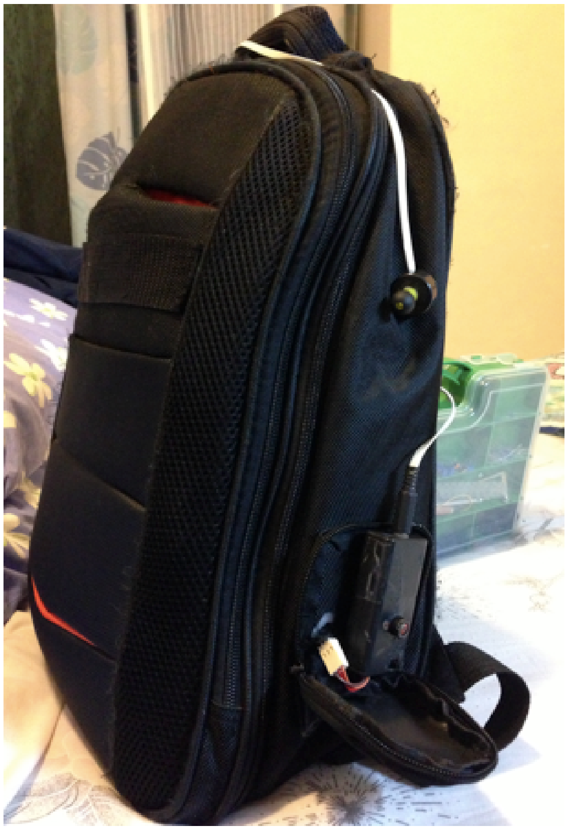
Backpack Crystal Radio

I was trying to bring the crystal radio out of the studio and into daily life.
However, whenever I use my umbrella crystal radio or hat crystal radio, people would give me a strange look.If we can hide a 300mmx400mm rectangular coil inside he backpack , we can build a backpack crystal radio and listen to musics as you travel.

And I did it! Checkout this youtube video:
http://www.youtube.com/watch?v=MbV9e09-Dxw [http://www.youtube.com/watch?v=MbV9e09-Dxw]
Although the volume of radio smaller than an umbrella, but you can still listen to some of the local radio stations clearly.
I can listen to the crystal radio every day on my way to work. The radio is loud enough and even louder in locations with a better radio reception.

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

Warning: If you are going on a flight or to a sensitive area, please remember to remove the coil from the backpack before going, otherwise you may not be able to board the aircraft.

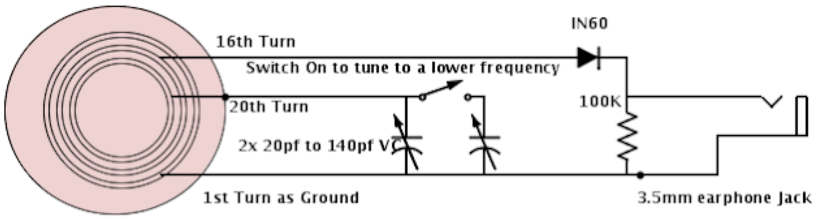


[http://4.bp.blogspot.com/-VY4RfayhLZ4/UXFIeGq43yI/AAAAAAAABBo/VgW_NXnFnTA/s1600/Screen+Shot+2013-04-19+at+8.33.07+PM.png]

[http://2.bp.blogspot.com/-iQektzNpj58/UXFIeGQI-NI/AAAAAAAABBw/_aTVC8cHqdE/s1600/Screen+Shot+2013-04-19+at+8.32.33+PM.png]

Circuit Diagram

Backpack Radio Circuit Diagram - http://billydiy.blogspot.hk



Coil: use any soft insulated wire (e.g. AWG 22). Wound a total of 20 turns on a box 300mm x 400mm
Then put the coil inside the cover of the backpack
See further details on how to build the backpack radio at http://billydiy.blogspot.hk

[http://1.bp.blogspot.com/-Q3ueJXl4Ak4/UXFIeEDQC-I/AAAAAAAABBs/nzQDabrMuzw/s1600/Screen+Shot+2013-04-19+at+7.28.36+PM.png]

Components you will need.

A backpack 300x400 mm or more, the larger the diameter, the more sensitive the radio.
The following instructions assume a 300x400 mm backpack.
Diode IN60, IN34A,
100K resistor,
40pf to 280PF variable capacitor (you can get it from an old radio)
3.5mm headphone jack,
18 meters of thin wire
A plastic battery case (those for two 2A Batteries) as a case for he crystal radio.
Crystal headset or 2K ohms or more high-impedance headphones. If you do not have one, follow instructions here to make one.

http://billydiy.blogspot.hk/2013/03/build-crystal-earphone-for-crystal.html

How to make it

A. Backpack Antenna

1. Found a a box the same size as the backpack. Then wind the wires around it to make the coil. A total of 20 turns are required. Then create a tap for the 16th turn. When finished, use tapes to tie the coil together. The coil inductance should be about 300uH. Then line-to-line capacitance is around 18PF. It will match well with a 20 pF to 280pF variable capacitor to tune into both radio stations at the low-end (531kHz) and the high-end (1453Khz).
2. Cut the front cover of the backpack to create an opening to install the coil.
3. Cut some more holes inside the backpack, to pass the wires inside the backpack to the side of the backpack.
4. Create a small side pocket to hold the radio with some cloth and zippers
5. Put the coil inside the opening created at the front cover of the backpack.
6. Pass the wires from the coil through the opening to the side pocket of the backpack.
7. Connect the the 1st turn to terminal 1, 16th turn to terminal 2, 20th turn to terminal 3.

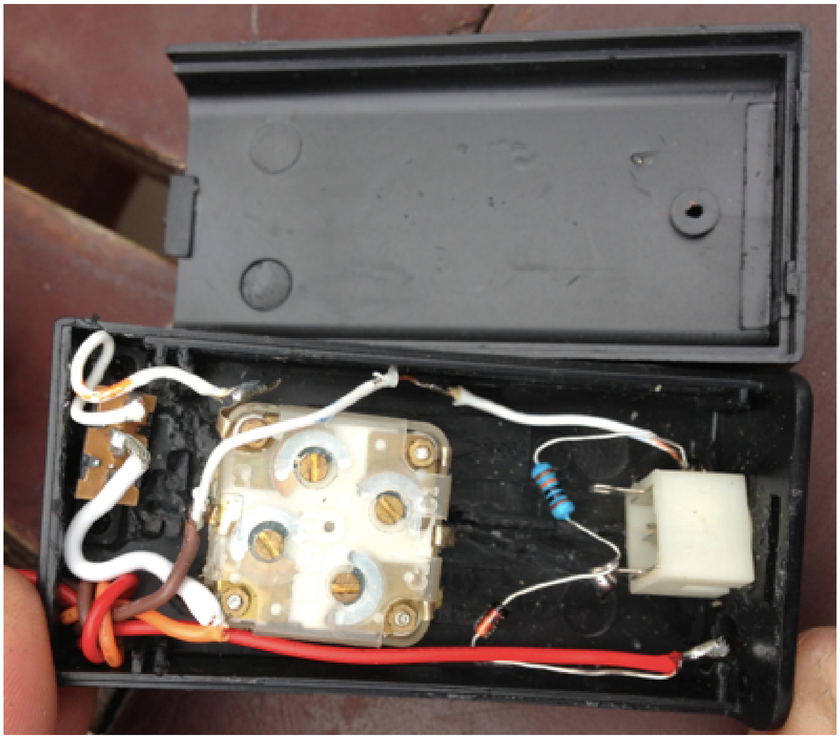
[http://1.bp.blogspot.com/-_X74ZnSUDrI/UXFIfW_66vI/AAAAAAAABCI/fldmEj8rjiM/s1600/Screen+Shot+2013-04-19+at+8.40.42+PM.png]

B. Crystal radio (without coil).

1. Drills holes in the plastic 2A battery box to install the headphone jack, variable capacitor and to pass the terminal wires.
2. Get the headphone jack and a variable capacitor installed, tighten the screws.
3. Refer to the circuit diagram and photos, weld the parts together.
4. The switch lead is connected to the two stator variable capacitor used to select the low-end or high-end radio.
5. Connect the ground wire from the headphone jack to terminal 1.

Connected diode to terminal 2.
Connect the variable capacitor stator to terminal 3.



[http://1.bp.blogspot.com/-udqhWYc-XzU/UXFIg-iJU8I/AAAAAAAABC4/lthXiUY-Z30/s1600/Screen+Shot+2013-04-19+at+8.44.11+PM.png]

[http://2.bp.blogspot.com/-E_u3RVnQhnY/UXFIfpf4izI/AAAAAAAABCU/XS1Hk91t8aY/s1600/Screen+Shot+2013-04-19+at+8.41.07+PM.png]

[http://2.bp.blogspot.com/-wwxL_Pv5Urw/UXFIgNM6bII/AAAAAAAABCo/o5WGImptXpU/s1600/Screen+Shot+2013-04-19+at+8.41.29+PM.png]

C. Connect the backpack antenna and the Crystal Radio together.

1. Attach the crystal radio to the side pocket of the backpack with a sticky tape.
2 Connect the terminal from the crystal radio to that of the backpack coil.
3. Plug the Crystal headphones into the headphone jack.
4 Place the backpack radio near a window or get to the streets to find an open space.
This backpack radio does not require a ground/earth connection, so you are free to walk on the street.
Align the backpack radio with the direction of the radio transmitting stations, slowly swing the backpack sideways to find the right location for best radio reception. At the same time, turn the knob of the variable capacitor tunes to radio stations. If you are located at a wide open space, you should be able to receive signals from a radio station. And then continue to adjust the angle to find the best reception.
You also can turn the switch on or off to select the low-end or high-end radio stations.

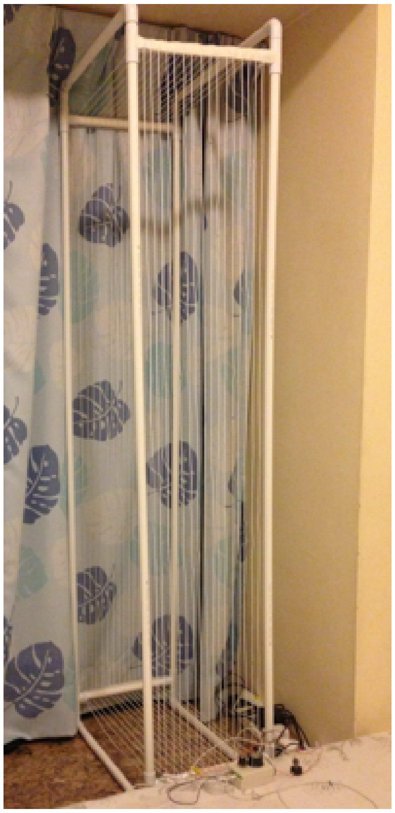
Battery-free Loud Huge Pipe Crystal Radio

Imagine building a huge crystal radio using PVC pipes as the wiring frame that is loud enough to drive the speaker.



[http://4.bp.blogspot.com/-1keQ1A93uUI/UWrmRcNMhpI/AAAAAAAABAo/0fRnzzDFLQw/s1600/Screen+Shot+2013-04-15+at+1.09.32+AM.png]

I saw this in the discussion forum in crystalradio.net.cn and try to build it with my own design.
This is a huge crystal radio 1.5 meter high, .3 meter wide with the coil wound on the plastic pipes you used to run electric wires into the walls. The pipes are exceptionally cheaper than I thought, only HKD 6 per 3 meters.

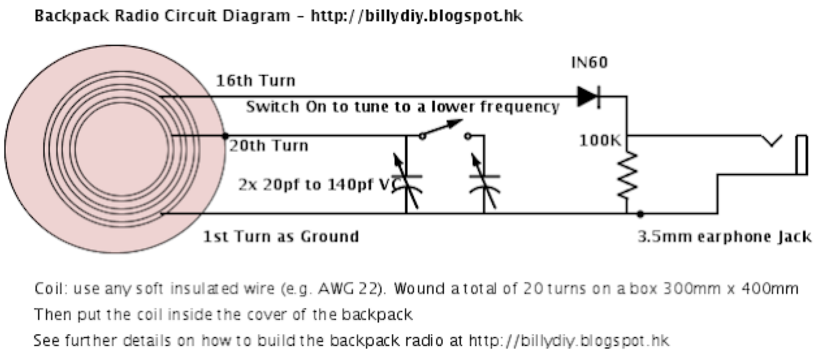
Setting up the framework takes one hour, and winding the coil another hour.
After all the hard work, I did it! The audio output level is two times louder than the umbrella radio and you can really drive the speaker. It's so loud that I end up adding a volume control to lower down the sound so I can listen to music while getting to sleep.

Checkout this youtube video:
http://www.youtube.com/watch?v=difYPuzWj4M [http://www.youtube.com/watch?v=difYPuzWj4M]

You can follow the instructions below to make this.

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

CIRCUIT DIAGRAM



Backpack Radio Circuit Diagram - http://billydiy.blogspot.hk

Coil: use any soft insulated wire (e.g. AWG 22). Wound a total of 20 turns on a box 300mm x 400mm
Then put the coil inside the cover of the backpack
See further details on how to build the backpack radio at http://billydiy.blogspot.hk

[http://1.bp.blogspot.com/-Q3ueJXl4Ak4/UXFIeEDQC-I/AAAAAAAABBs/nzQDabrMuzw/s1600/Screen+Shot+2013-04-19+at+7.28.36+PM.png]

Parts you'll need.

1. Diode IN60, or IN34A
2. Variable Resister 100K type B (for volume control).
3. 30pf to 360pf Variable Capacitor (you can get it from an old radio if you cannot buy it),
4. 2.5mm earphone jack,
5. 3.5 meter of thin wires in three different colours (black for earth, red for antenna, orange for detector)
6. Three crocodile clamps of the same colours.
7. A transparent plastic case for the crystal radio. 60mmx40mmx20mm
8. A crystal earphone. If you do not have it, you can buy it from amazon or e-Bay (around HKD 100 including all the handling fees) or make one yourselves at HKD 10 following the instructions from my other blog posting here:
   How to make a crystal earphone for crystal radios [http://www.blogger.com/blogger.g?blogID=2311644141825422235#editor/target=post;postID=1827613235001197062]

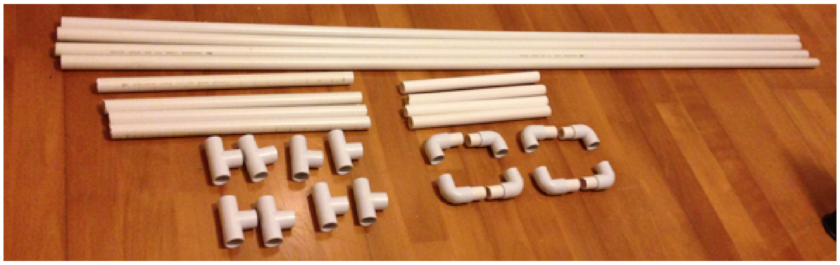
   [http://2.bp.blogspot.com/-ALf15x9ipP0/UV0zuFSOrRI/AAAAAAAAA38/Xf4NU5Wtze4/s1600/Screen+Shot+2013-04-04+at+4.02.38+PM.png]
9. 70 meters of any insulated wires. I used the AWG 22 plastic wire. You can also use AWG 26 which is thinner and lighter. However, the thicker the wire, the more radio wave you capture and the higher sensitivity and higher audio output.

[http://2.bp.blogspot.com/-rYyEBQEY_B4/UVmUKnniVil/AAAAAAAAA0Q/iua6obT96AQ/s1600/IMG_1200.JPG]

You can get most of these from electronic ships in Shamshupo, except the variable capacitor. You can easily buy some old recycled walkman with radios for HKD20-50 from the hawkers in Ip Liu Street in Sham Shui Po. The other way is to go to taobao.com to buy them online and ship to HK. The goods is RMB 5, but the shipping fees is minimum RMD 30, so not worth it unless you buy in great quantity. For the Crystal Earphone, it's very hard to buy nowadays. Refer to my other post to make one yourselves. DIY Crystal Earphone for Crystal Radios [http://billydiy.blogspot.com/2013/03/build-crystal-earphone-for-crystal.html]

From the Hardware store:

10. Buy 3 x 20mm diameter PVC pipes , each 3 meters long - around HK$6 each (ask the shop keeper to cut it in half so you will have 6 x 1.5meter pipes, easier to carry home).
11. 8 x L shape PVC pipe joints for 20mm pipes - around $1.5 each
12. 8 x T shape PVC pipe joints for 20mm pipes - around $1.5 each



[http://1.bp.blogspot.com/-8MIAYBPNieQ/UWrmUGn8PgI/AAAAAAAABBA/39zUYA-DFrE/s1600/Screen+Shot+2013-04-15+at+1.10.57+AM.png]

TOOLS

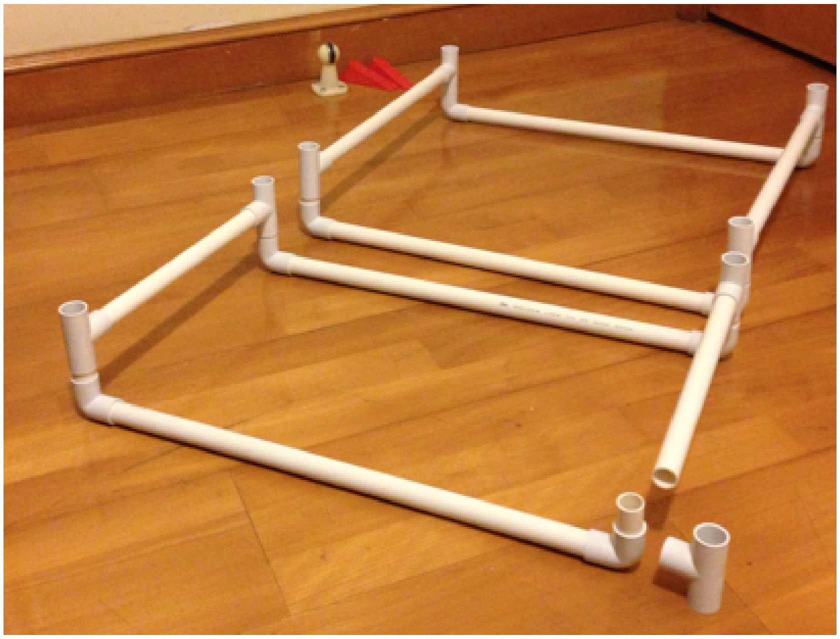
1. Solder Iron
2. Saw
3. White Tapes

HOW TO MAKE IT.

A. Create the Hug Pipe Antenna

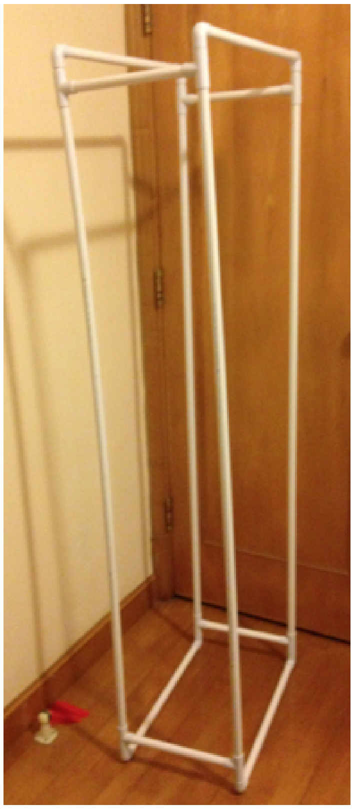
1. First build the wiring frame:

- Use the saw cut out the pipes into the following pieces:
  - 4 x 1.5 meter pipes
  - 4 x 470mm pipes.
  - 4 x 270mm pipes
  - 8 x 35mm pipes for connecting T-Joints and L-joints together
- connect one 470mm pipe to a L-Joint then to a 35mm pipe then to an T-joint. Then connect the 270mm pipe to the T-Joint.
- Repeat the above to create the base and the top as below.



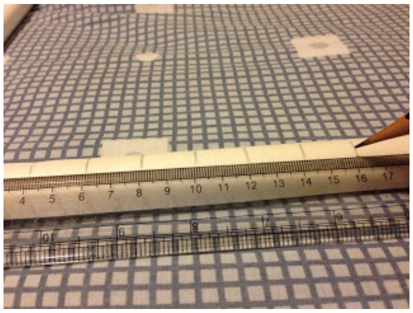
[http://1.bp.blogspot.com/-bh0dkEeMbYY/UWrmUFhfAyI/AAAAAAAABBI/szII001q-Gs/s1600/Screen+Shot+2013-04-15+at+1.11.10+AM.png]

- Now insert the 4 x 1.5 meter pipes into the T-joints (connecting the square base with the square tops).
- Fastern the joins by applying pressure.



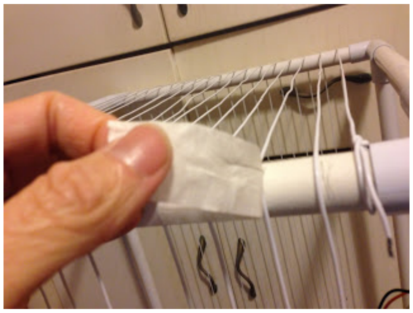
[http://3.bp.blogspot.com/-sj-pnbjhl98/UWrm28ihP5I/AAAAAAAABBQ/9Rq2RzNoQas/s1600/Screen+Shot+2013-04-15+at+1.11.54+AM.png]

2. Put the white tapes onto the 4 edges of the base and the top of the frame. Then put a mark on the tape every 20mm. This is the separation between coils.



[http://1.bp.blogspot.com/-60fMfQJ6aNk/UWgDgscyt1I/AAAAAAAAA_k/MFIUQpX1B1g/s1600/IMG_1310.JPG]

3. Put another tape onto the first tape, for sticking the wire in place.
4. Start winding the coil. Lift up the outer tape, put the wire it at the places that we marked, and stick the outer tape to hold the wire, then continue the wind all the 17 turns.



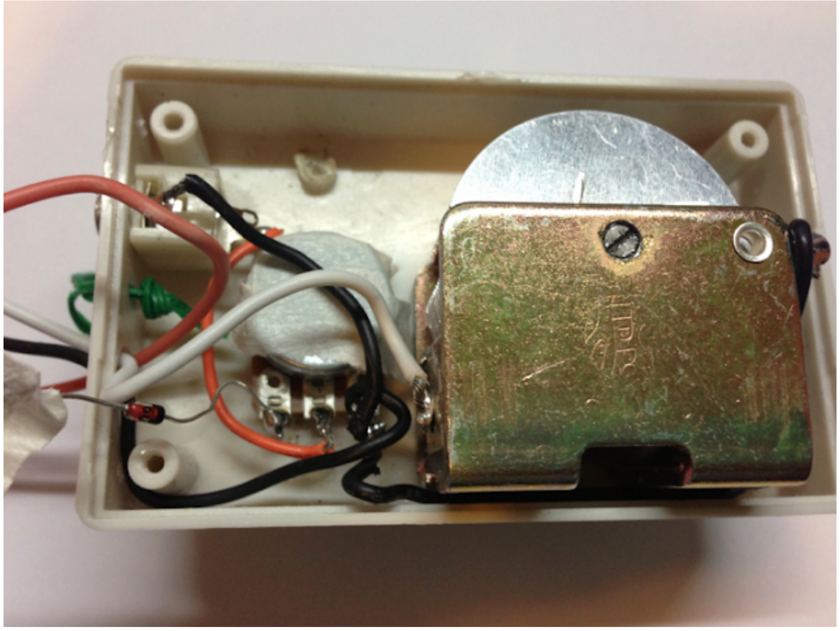
[http://4.bp.blogspot.com/-1LAX7awkscM/UWgDnpkzU5I/AAAAAAAAA_s/IwkKt3quUS4/s1600/IMG_1311.JPG]

5. After winding is done, create the tabs by cutting out the jacket of the wire and expose the copper inside for every turn. At around 80mm above the base.
6. If you have a inductance meter, measure the inductance of the whole coil. It should be close to 300 uh. As shown below, the inductance of the coil is around 294 uH

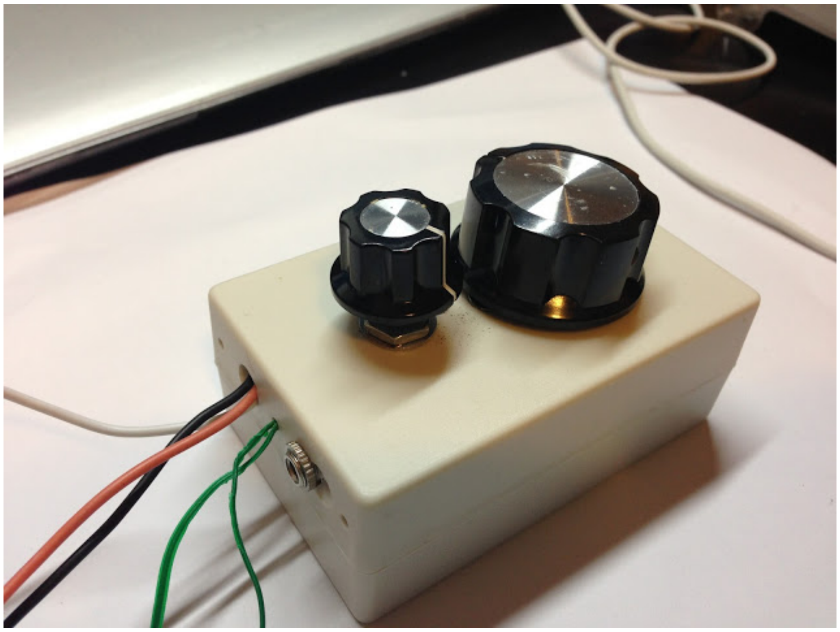
[http://2.bp.blogspot.com/-1hLmBI9EIf8/UWfwOGp-OxI/AAAAAAAAA-M/eJV6TJ92p1Y/s1600/IMG_1280.JPG]

B. Make the crystal radio (without the coil).

1. Drill holes on the plastic case to fit the earphone jacks, variable capacitor knobs, and the variable resistor knobs, and one more hole to pass the wires for the crocodile clamps, and one more hole for a thin wire to hang the box.
2. Mount the earphone jacks , the variable capacitor and the variable resistor onto the case and fasten the screws.
3. Refer to the circuit diagram and the real life wiring photo, solder the parts together.
4. Connect a black wire to the ground of the Jack and connect the other end to a black crocodile clamp.
5. Connect a white wire to the tip C1 of the variable capacitor.
6. Connect an orange wire to the diode and connect the other end to a yellow crocodile clamp.



[http://2.bp.blogspot.com/-KB-_5OFCxEg/UWf4MAx0hLI/AAAAAAAAA-w/sKXMpRWu6zk/s1600/Screen+Shot+2013-04-12+at+8.03.34+PM.png]



[http://4.bp.blogspot.com/-zpN-V5fYIGk/UWf3ymcjDJI/AAAAAAAAA-o/mTmsqaNg290/s1600/IMG_1301.JPG]

C. Put the Huge Pipe Antenna and the Crystal Radio together.

1. Stand the huge pipe radio next to the window. Use some boxes to raise the frame at least 80mm above any concrete or steel platforms. Otherwise, all the radio signal will be drained to the earth through these concrete or steel frames of your window.
2. Connect black crocodile clamp from crystal radio (for ground) to the tab of the turn 0 (beginning of the coil).
3. Connect the red crocodile clamp (for tuning) to the tab of the last turn (end of the coil).
4. Connect the yellow crocodile clamp (for detector) to the tab of the 14th turn.
5. Plug a crystal earphone to the earphone jack of the radio.
6.

7. Point the huge pipe antenna coil towards the location of the transmitters , or try swing it sideways slowly to find the right spot. At the same time turn the knob of the variable capacitor to tune to a station.
8. If your window is facing a wide open space you should be able to tune to a station. If your window is blocked by another building, then then the signal may be weaken. But keep trying.
9. Once you find the best spot, you can try moving the yellow crocodile clamp up or down to the the other tabs to see if you can get a louder signal. Depending on the actual situation, you may need to make more tabs on the other turns to get the loudest signal. Also, by connecting to different tabs, you can tune into other part of the AM radio frequency to tune into more radio stations.
10. Good Luck and Happy Listening.

Battery-free Hat Crystal Radio

Continuing on with the Umbrella Crystal Radio [http://billydiy.blogspot.hk/2013/04/umbrella-crystal-radio.html] , Billy's DIY Dreamshop brings you the Battery-free Hat Crystal Radio.

Inspired by my friend, and following the similar concept as the umbrella radio, I want to shrink the spiderweb coil from 1 meter in diameter down to 0.3 meter. This will fit nicely on something you can wear, for example a hat or a necklace.

And I did it! Though the audio output level is only half of that of the umbrella radio you can listen clearly to 3 HK local radios from an open area.

Now, you can wear a hat and listen to radio! Just make sure you point your hat at the direction of the radio transmitters see this link. Hong Kong AM Radio Stations and Transmission Locations [http://billydiy.blogspot.hk/2013/04/hong-kong-am-radio-stations-and.html]

You can follow the instructions below to make this.

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

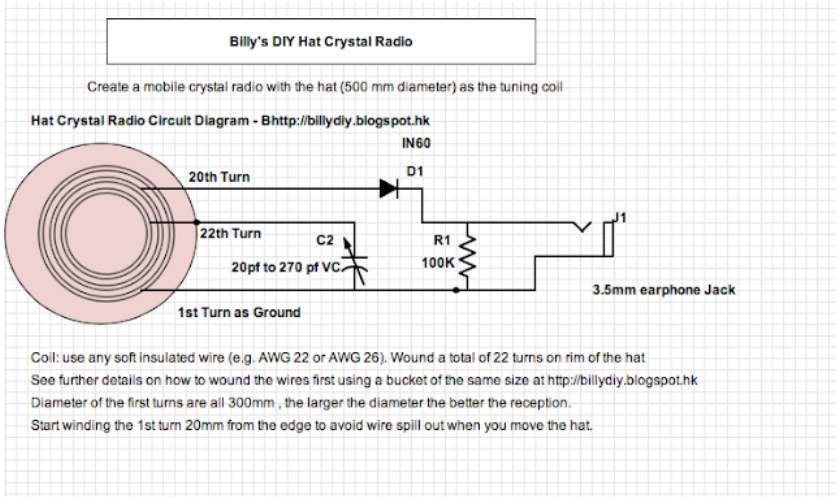
CIRCUIT DIAGRAM

Dynamic Views theme. Powered by Blogger.



Billy's DIY Hat Crystal Radio

Create a mobile crystal radio with the hat (500 mm diameter) as the tuning coil

Coil: use any soft insulated wire (e.g. AWG 22 or AWG 26). Wound a total of 22 turns on rim of the hat
See further details on how to wound the wires first using a bucket of the same size at http://billydiy.blogspot.hk
Diameter of the first turns are all 300mm , the larger the diameter the better the reception.
Start winding the 1st turn 20mm from the edge to avoid wire spill out when you move the hat.

[http://3.bp.blogspot.com/-CeHfFT2VkjA/UXFXAFbEoFI/AAAAAAAABDg/o53rnpWT9XA/s1600/Screen+Shot+2013-04-19+at+10.38.24+PM.png]

Parts you'll need.

1. A straw hat with a diameter of 500mm or above, the larger the diameter, the louder will be your radio. The following instructions assumes a 500mm-diameter hat. Adjust the length of wires you need accordingly if you have a bigger hat.
2. Any thin wire of any thickness to wound a coil of 22 turns and diameter 300mm around the hat.
3. Diode IN60,
4. Resister 100K,
5. 270pf or 360pf Variable Capacitor (you can get it from an old radio if you cannot buy it),
6. 3.5mm earphone jack,
7. 1.5 meter of thin wires in three different colours (black for earth, red for antenna, orange for detector)
8. Three crocodile clamps of the same colours.
9. A transparent plastic case for the crystal radio. 60mmx40mmx20mm
10. A crystal earphone. If you do not have it, you can buy it from amazon or e-Bay (around HKD 100 including all the handling fees) or make one yourselves at HKD 10 following the instructions from my other blog posting here:
    How to make a crystal earphone for crystal radios [http://www.blogger.com/blogger.g?blogID=2311644141825422235#editor/target=post;postID=1827613235001197062]

    [http://2.bp.blogspot.com/-ALf15x9ipP0/UV0zuFSOrRI/AAAAAAAAA38/Xf4NU5Wtze4/s1600/Screen+Shot+2013-04-04+at+4.02.38+PM.png]
11. Twenty five meters of any wires protected by rubber stealth. I used the AWG 22 plastic wire. You can also use AWG 26 which is thinner and lighter. However, the thicker the wire, the more radio wave you capture and the higher sensitivity and higher audio output.

[http://2.bp.blogspot.com/-rYyEBQEY_B4/UVmUKnniViI/AAAAAAAAA0Q/iua6obT96AQ/s1600/IMG_1200.JPG]

You can get most of these from electronic ships in Shamshupo, except the variable capacitor. You can easily buy some old recycled walkman with radios for HKD20-50 from the hawkers in Ip Liu Street in Sham Shui Po. The other way is to go to taobao.com to buy them online and ship to HK. The goods is RMB 5, but the shipping fees is minimum RMD 30, so not worth it unless you buy in great quantity.
For the Crystal Earphone, it's very hard to buy nowadays. Refer to my other post to make one yourselves. DIY Crystal Earphone for Crystal Radios [http://billydiy.blogspot.com/2013/03/build-crystal-earphone-for-crystal.html]

TOOLS

1. Solder Iron
2. Leather hole puncher for cutting 2mm holes. The paper hole puncher is too big. You can use a nail to cut the hole if you do not have the leather hole puncher.

HOW TO MAKE IT.

A. Create the Hat Antenna

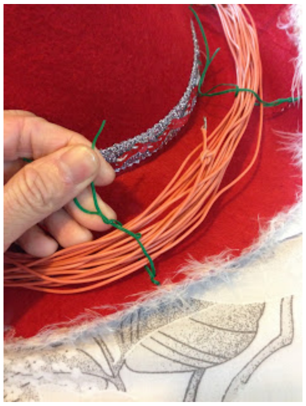
1. First let's create the hat antenna. Use the hole cutter or a sharp object to cut two small holes on the rim of the hat at least 20mm from the edge. This is for tying the wire to hold the coil in place. Repeat this at the five other places around the hat so you can hold the coil firmly later on.

[http://4.bp.blogspot.com/-893XFDdMYdM/UV0k8P5lzoI/AAAAAAAAA2o/SlgSne79_kA/s1600/IMG_1221.JPG]

2. Find a round bucket or rubbish bin around the same size as the coil you are going to wind. Then wind the coil using the thin wire. Total 22 turns. When finish, use the twist tie or wires to tie the coil at the six places to hold it in place and also later on to mount onto hat.

[http://3.bp.blogspot.com/-VfkbZ_4bKJk/UV0mzG47ivI/AAAAAAAAA20/cCv0k944h1k/s1600/IMG_1239.JPG]

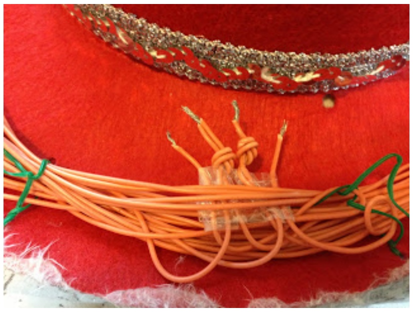
3. Mount the coil onto the hat by tying the twist tie or wires onto the six pair of holes you created in step A1.



[http://3.bp.blogspot.com/-C-ZN1turigQ/UV0oNC7Q0aI/AAAAAAAAA3E/Zwe--tYlUlQ/s1600/IMG_1240.JPG]

4. Create Tabs for connection to the Crystal Radio set at the following turns.

- Turn 0 - Beginning of the coil
- Turn 18
- Turn 20
- Turn 22 - End of the coil.



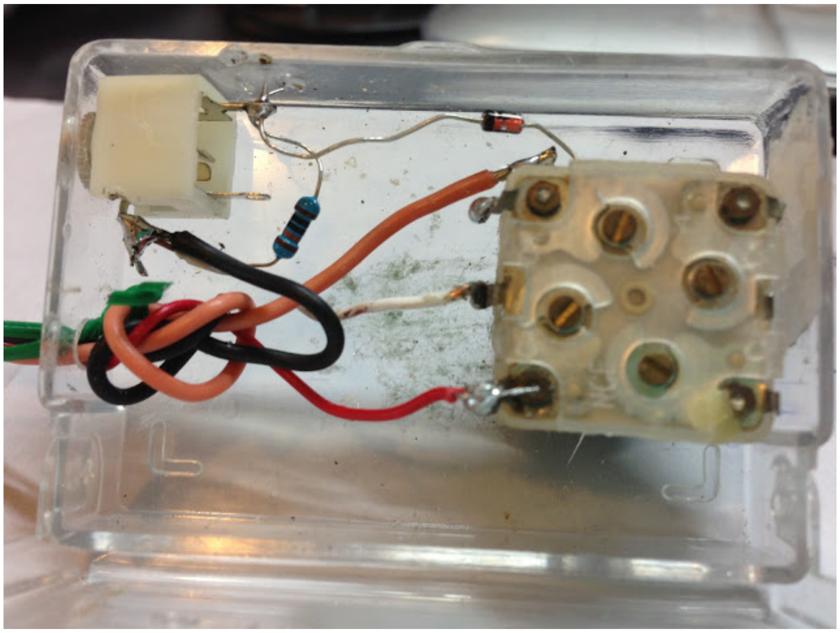
[http://4.bp.blogspot.com/--R93N5a8YKQ/UV0qiDyOeVI/AAAAAAAAA3Y/9DS09uyYsvo/s1600/IMG_1241.JPG]

The inductance of the coil is around 338 uH

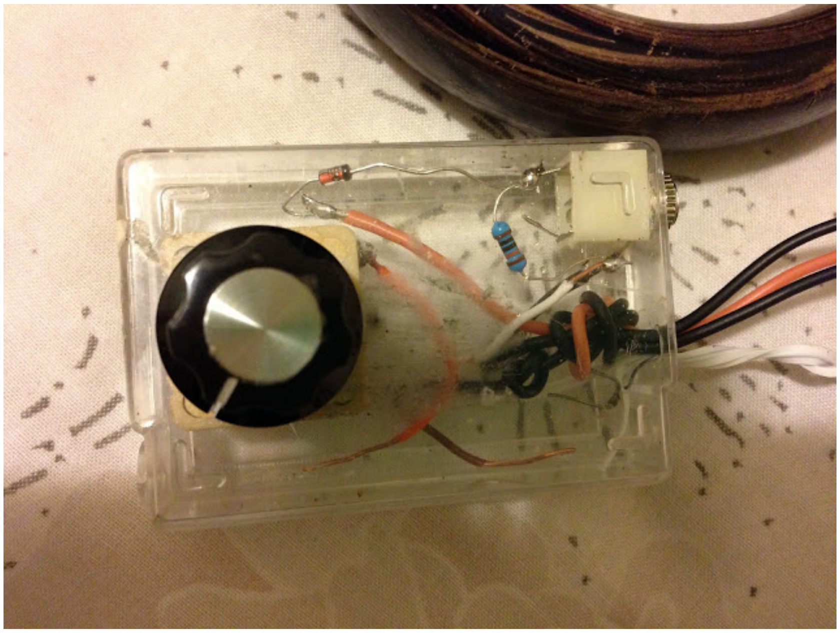
[http://1.bp.blogspot.com/-gTuPjJ-sELo/UWLnugq3oDI/AAAAAAAAA9Y/qPrKbJeMfs0/s1600/IMG_1275.jpg]

B. Make the crystal radio (without the coil).

1. Drill holes on the plastic case to fit the earphone jacks, variable capacitor knobs, and one more hole to pass the wires for the crocodile clamps.
2. Mount the earphone jacks and the variable capacitor onto the case and fasten the screws.
3. Refer to the circuit diagram and the real life wiring photo, solder the parts together.
4. Connect a black wire to the ground of the Jack and connect the other end to a black crocodile clamp.
5. Connect a red wire to the tip C1 of the variable capacitor.
6. Connect an orange wire to the diode and connect the other end to a yellow crocodile clamp.



[http://1.bp.blogspot.com/-FsoOXwgYmUI/UV1VCEnXRQI/AAAAAAAAA6Y/76a4H0CYx5Y/s1600/IMG_1260.JPG]



[http://4.bp.blogspot.com/-nygOMUZib2c/UVmffBrMV9I/AAAAAAAAA10/8jQaminvcT8/s1600/IMG_1204.JPG]

C. Put the hat antenna and the crystal radio together.

1. Hang the crystal radio from hat, or on the rim of the hat using a piece of wire to tie it.
2. Connect black crocodile clamp from crystal radio (for ground) to the tab of the turn 0 (beginning of the coil).
3. Connect the red crocodile clamp (for tuning) to the tab of the 22 th turn (end of the coil).
4. Connect the yellow crocodile clamp (for detector) to the tab of the 20th turn.
5. Plug a crystal earphone to the earphone jack of the radio.
6. Bring the hat down to the street and find an empty space, or get close to the window
7. This crystal radio does not require an earth, so you can walk freely on the street
8. Point the hat towards the location of the transmitters , or try swing it sideways slowly, and up and down to find the right spot. At the same time turn the knob of the variable capacitor to tune to a station.
9. If you have a wide open space you should be able to tune to a station. Then continue to adjust the angle of the hat to find the direction with the best reception.
10. Once you find the best spot, you can try moving the yellow crocodile clamp down to the the 18th tabs to see if you can get a louder signal. Depending on the actual situation, you may need to make more tabs on the other turns to get the loudest signal.

Next

I will try to build an FM Crystal radio. There are different circuits being tested.

Battery-free Umbrella Crystal Radio

Create a battery free, crystal radio using an umbrella as the tuning coil which doubles up as a powerful spiderweb antenna.

You can now walk down the beach with this umbrella crystal radio.
Enjoy sun bathing while listening to the crystal radio!

The umbrella coil can double up as a super strong spiderweb antenna for testing your crystal radio even at home!
Just put the umbrella antenna close to your window and point to the direction of the radio transmission station.

Checkout this Youtube video:
http://www.youtube.com/watch?v=MElL_0IpV4 [http://www.youtube.com/watch?v=MElL_0IpV4g]

I have done one more field test of the radio.

http://www.youtube.com/watch?v=fYvUTIYZ43I

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

What is a Crystal Radio

Crystal radio is a the simplest radio that runs purely on energy captured from the radio wave and do not require a battery or other forms of electricity supply.
Radio signals are transmitted by the radio stations in HK, e.g. RTHK or Commercial Radio , or the Metro radio, or even from stations across the border from mainland China. See here for details
Hong Kong AM Radio Stations and Transmission Locations [http://billydiy.blogspot.hk/2013/04/hong-kong-am-radio-stations-and.html]

I made crystal radio since I was a teenager. At that time I used to fail, because getting a good antenna set up was and still is a challenge in a concrete jungle like Hong Kong especially if you are living in a high rise apartment; and you are not rich enough to own the roof (i.e. me). Now I can resolve this issue with this umbrella radio that doubles up as a powerful antenna!

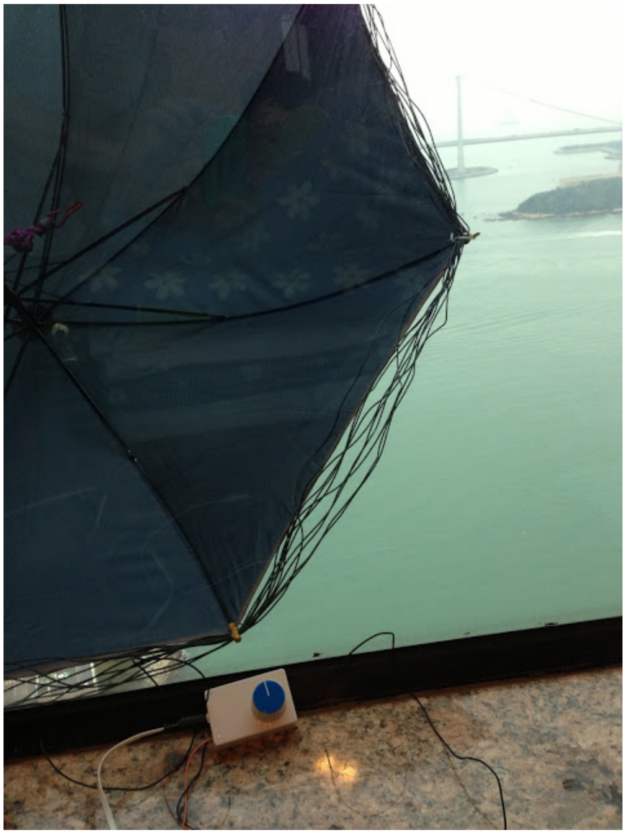
[http://3.bp.blogspot.com/-Ekdw-4ecSNU/UYpvDTcNzQI/AAAAAAAABIY/dBdn7ASU8ZY/s1600/IMG_1757.JPG]

From Dream to Creation

I notice that there are lots of web postings for mobile crystal radios with huge antenna wound on a Cross made from meter long PVC pipes. This is great. However, the bulky set up is pretty bulky and very hard to transport around.
What if we can replace the cross with a meter-wide umbrella.
Turning on the crystal radio will be as easy as opening an umbrella.
That's how I started the creation of my first umbrella radios. Version 1 of the product (see below) was built in a rush in just 2 hours. It achieve the function to receive many radio stations and the signal is pretty strong too. However, it's built on a extra-large golf umbrella , and the wires are wound on tiny holes at the tip of the umbrella. So, wires tend to be exposed when you close the umbrella.

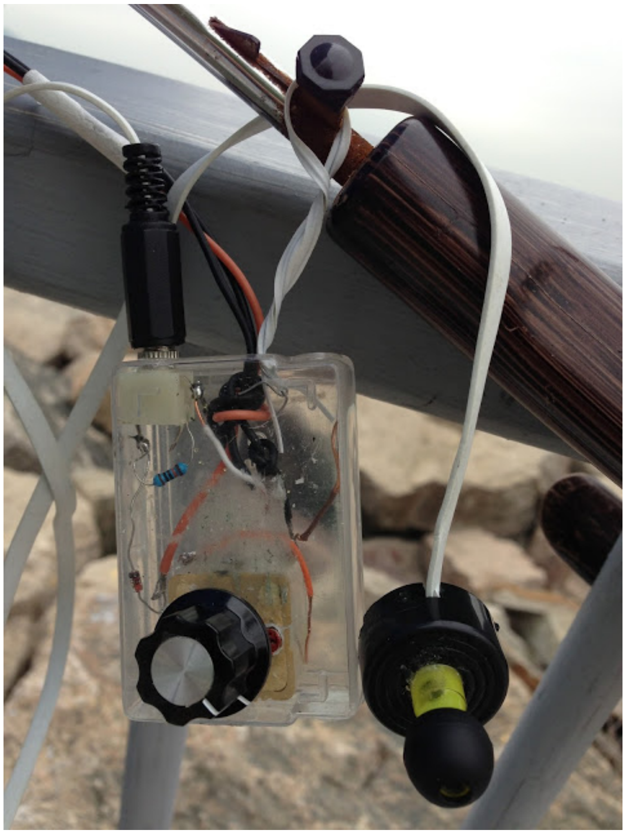


[http://2.bp.blogspot.com/-iUavwbbZZls/UVmpG30vncl/AAAAAAAAA2A/d-5M5s7iUuE/s1600/IMG_1109.JPG]

Umbrella Antenna Version 1.

Then I think of better ways to wind the coil inside the umbrella and created umbrella crystal radio version 2.
So, now even if it's raining (and no lightning), I can open up the umbrella with the coil safely inside, and me happily listening to the musics from the crystal radio. I call it the Umbrella Crystal Radio.

Dynamic Views theme. Powered by Blogger.

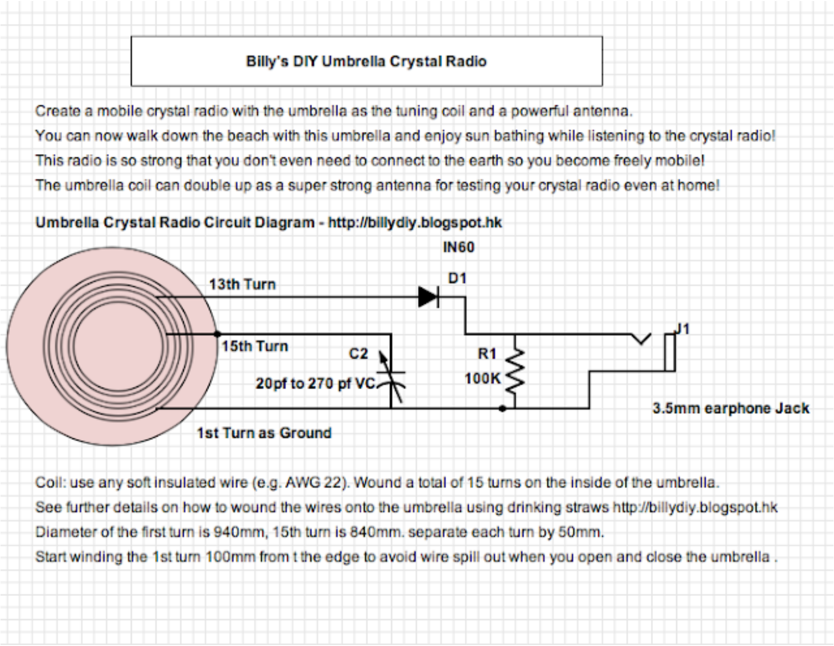


[http://3.bp.blogspot.com/-djZ69vC6Qvc/UVmRXlzSAQI/AAAAAAAAAz0/EAgOuHobJRA/s1600/IMG_1178.JPG]

Mounting the Umbrella radio on the fence, reception is super strong.

In this blog, I will show you how to build this umbrella crystal radio , please follow instructions part A, B, and C.
If you already have an existing crystal radio, you can still use the umbrella as the antenna.
Just follow part A to build the umbrella antenna, then jump to part D to use it as an antenna for your existing crystal radios. Just place the umbrella next to your window and point at the right direction to receive the radio waves.

Circuit Diagram



Billy's DIY Umbrella Crystal Radio

Create a mobile crystal radio with the umbrella as the tuning coil and a powerful antenna.
You can now walk down the beach with this umbrella and enjoy sun bathing while listening to the crystal radio!
This radio is so strong that you don't even need to connect to the earth so you become freely mobile!
The umbrella coil can double up as a super strong antenna for testing your crystal radio even at home!

Umbrella Crystal Radio Circuit Diagram - http://billydiy.blogspot.hk

Coil: use any soft insulated wire (e.g. AWG 22). Wound a total of 15 turns on the inside of the umbrella.
See further details on how to wound the wires onto the umbrella using drinking straws http://billydiy.blogspot.hk
Diameter of the first turn is 940mm, 15th turn is 840mm. separate each turn by 50mm.
Start winding the 1st turn 100mm from t the edge to avoid wire spill out when you open and close the umbrella .

19+at+10.41.10+PM.png]

Parts you will need

1. An umbrella around 1 meter in diameter, 8 or more ribs.
The instructions below assumes that you have an umbrella of 8 ribs, and 1 meter in diameter.

You can choose the following types of umbrellas each with a different diameter. The bigger the diameter the better the radio reception, and the louder the radio. However, a regular umbrella of 900mm is good enough.

Diameter of different types of umbrellas (photo below from left to right):

Golf umbrella	1230 mm
Car umbrella	1180 mm
Large umbrella	1070 mm
Regular umbrella	900mm

[http://1.bp.blogspot.com/-vF1exGODXlI/UX0go2x7gpI/AAAAAAAABEE/DOhOlg73ea4/s1600/Screen+Shot+2013-04-28+at+9.12.53+PM.png]

Crook Handle

[http://1.bp.blogspot.com/-u4H0b1n0S7k/UVmK5XZCOGI/AAAAAAAAAzQ/30lQ-EwFZ98/s1600/Screen+Shot+2013-04-01+at+9.14.05+PM.png]

2. 8 or more Drinking Straws of diameter 8mm , those from Mac Donald are perfect. You need as many as the number of ribs your umbrella has. Most umbrella has 8 ribs.

[http://2.bp.blogspot.com/-0mf8l_j4jFo/UVmVZW8yHbI/AAAAAAAAA0Y/ImJKk9N-JUI/s1600/IMG_1201.JPG]

3. Diode IN60,
4. Resister 100K,
5. 270pf or 360pf Variable Capacitor (you can get it from an old radio if you cannot buy it),

6. 3.5mm earphone jack,

7. 1.5 meter of thin wires in three different colours (black for earth, red for antenna, orange for detector)
8. Three crocodile clamps of the same colours.

9. Fifty meters of any regular electric wires. I used the AWG 22 plastic wire. You can also use AWG 26 which is thinner and lighter. However, the thicker the wire, the more radio wave you capture and the higher sensitivity and higher audio output.

PROFESSIONAL WIRE & CABLE

Dynamic Views theme. Powered by Blogger.

10. A transparent plastic case for the crystal radio. 60mmx40mmx20mm
11. A crystal earphone. If you do not have it, you can buy it from amazon or e-Bay (around HKD 100 including all the handling fees) or make one yourselves at HKD 10 following the instructions from my other blog posting here: How to make a crystal earphone for crystal radios [http://www.blogger.com/blogger.g?blogID=2311644141825422235#editor/target=post;postID=1827613235001197062]

[http://4.bp.blogspot.com/-ALf15x9ipP0/UV0zuFSOrRI/AAAAAAAAA34/rPr_l0AV14Y/s1600/Screen+Shot+2013-04-04+at+4.02.38+PM.png]

You can get most of these from electronic ships in Shamshupo, except the variable capacitor. You can easily buy some old recycled walkman with radios for HKD20-50 from the hawkers in Ip Liu Street in Sham Shui Po. The other way is to go to taobao.com to buy them online and ship to HK. The goods is RMB 5, but the shipping fees is minimum RMD 30, so not worth it unless you buy in great quantity. For the Crystal Earphone, it's very hard to buy nowadays. Refer to my other post to make one yourselves. DIY Crystal Earphone for Crystal Radios [http://billydiy.blogspot.com/2013/03/build-crystal-earphone-for-crystal.html]

Tools

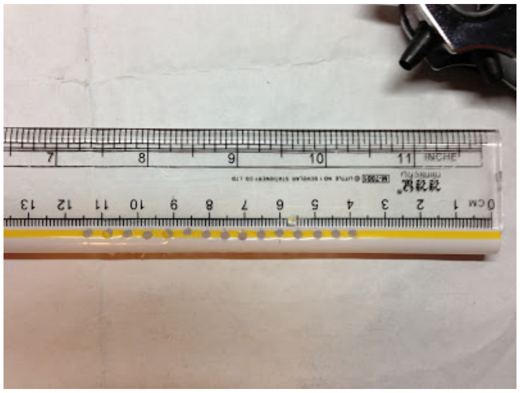
1. Solder Iron
2. Leather hole puncher for cutting 2mm holes. The paper hole puncher is too big. You can use a nail to cut the hole if you do not have the leather hole puncher.

[http://4.bp.blogspot.com/-0qEaSjjIEOY/UVmW0Lca6LI/AAAAAAAAA0o/ZDfWv6M4EWY/s1600/IMG_1202.JPG]

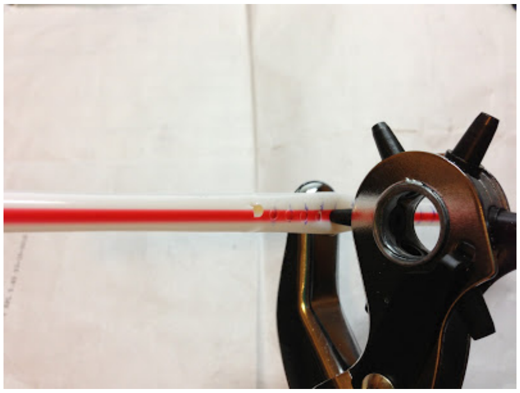
How to make it.

A. Create the Umbrella Antenna

1. First let's create the umbrella antenna. Use the hole cutter to cut fifteen 2 mm holes on the drinking straw. You may want to mark it first with your ruler before cutting. Start from 40mm, then mark the hole to be cut every 5mm until you reach 115mm.

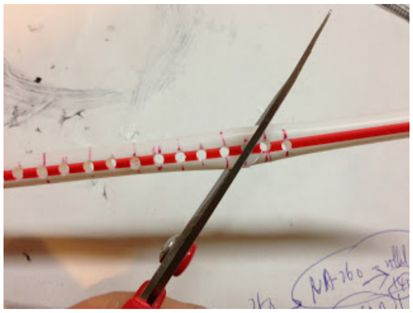


[http://2.bp.blogspot.com/-dLe9r1nIizA/UVmV7CXcN2I/AAAAAAAAA0g/RDf5clSyWRE/s1600/IMG_1161.JPG]



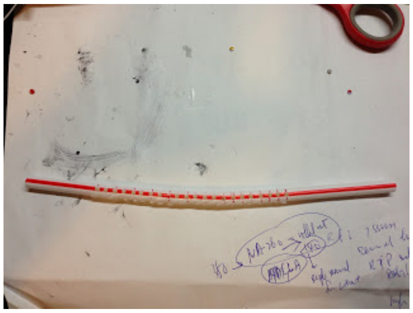
[http://2.bp.blogspot.com/-lxJ5UFcGkPA/UVmXeszhaLI/AAAAAAAAA00/ezbypv5yixE/s1600/IMG_1159.JPG]

2. At each hole cut a slanting slot on the side of the straw so it'll be easier to pull the wire over.



[http://4.bp.blogspot.com/-RGxWhist1V0/UYPQqRjwJjI/AAAAAAAABE0/mS6yv3Vzj_c/s1600/IMG_1697.JPG]

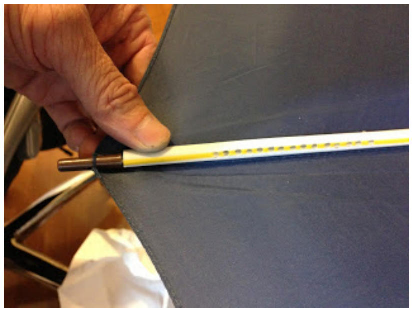
This is how a finished straw looks.



[http://1.bp.blogspot.com/-YdDRP_1dImY/UYPQwKXCcOI/AAAAAAAABE8/sC39Oolj0vg/s1600/IMG_1698.JPG]

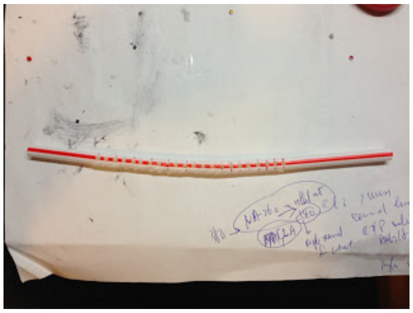
3. Remove all 8 tips from the ribs of the umbrella. Insert the straws into the rib, then put the tip back on again.

[http://1.bp.blogspot.com/-cOc0Dk3oKQU/UVmX1I2aZdI/AAAAAAAAA04/-0C0Ycr-3M0/s1600/IMG_1164.JPG]

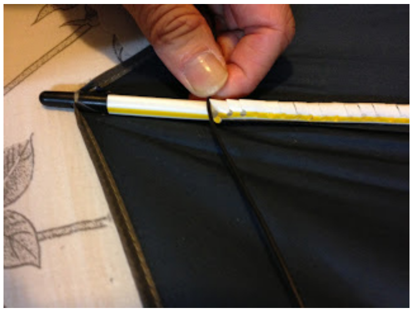


[http://3.bp.blogspot.com/-qH__j-4e3ZY/UVmYCwPvb8I/AAAAAAAAA1A/J27ffuqfTaA/s1600/IMG_1166.JPG]

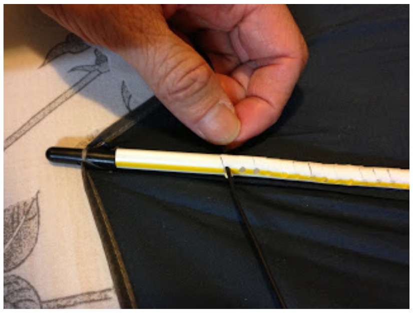
4. Wind the coil by by pressing the wire in the slanted openings to the holes of the drinking straw. Lock the wire securely into the hole before going for the next turn.



[http://4.bp.blogspot.com/-P0ZJzLBdyOI/UYU-gtQoltI/AAAAAAAABFY/Fxb8kDM63sA/s1600/IMG_1699.JPG]



[http://2.bp.blogspot.com/--_nFnE0F08w/UYU-gf7G2KI/AAAAAAAABFQ/MqkMGKTFw-A/s1600/IMG_1700.JPG]



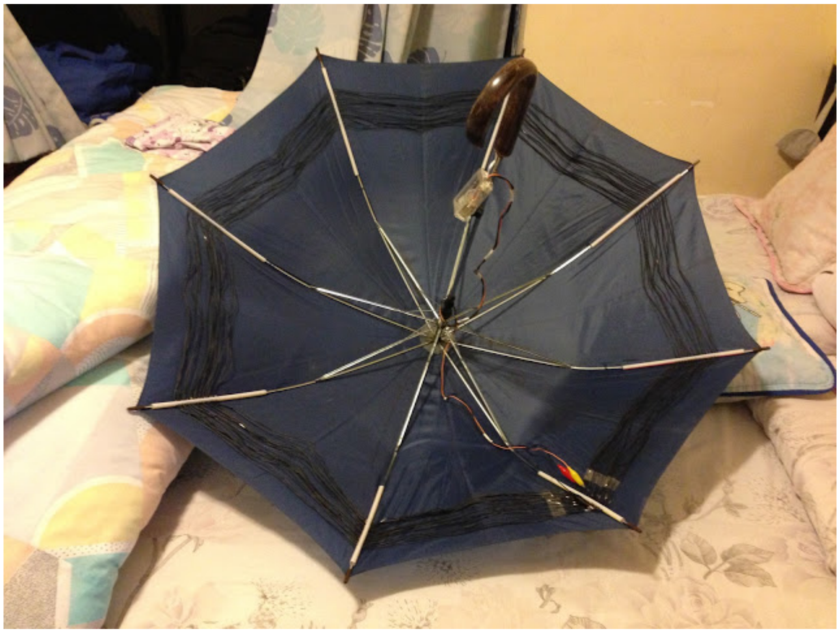
[http://1.bp.blogspot.com/-rvvGjhK4knM/UYU-gt1UkhI/AAAAAAAABFU/ccZAtrcXLR8/s1600/IMG_1701.JPG]

[http://4.bp.blogspot.com/-x1PUd5cN6_4/UYU-h-piWEI/AAAAAAAABFw/bvAD4aEryYY/s1600/IMG_1704.JPG]

[http://3.bp.blogspot.com/-ToDmUd1wJFw/UYU-ivDSBCI/AAAAAAAABF0/QLGfzErEjF0/s1600/IMG_1705.JPG]

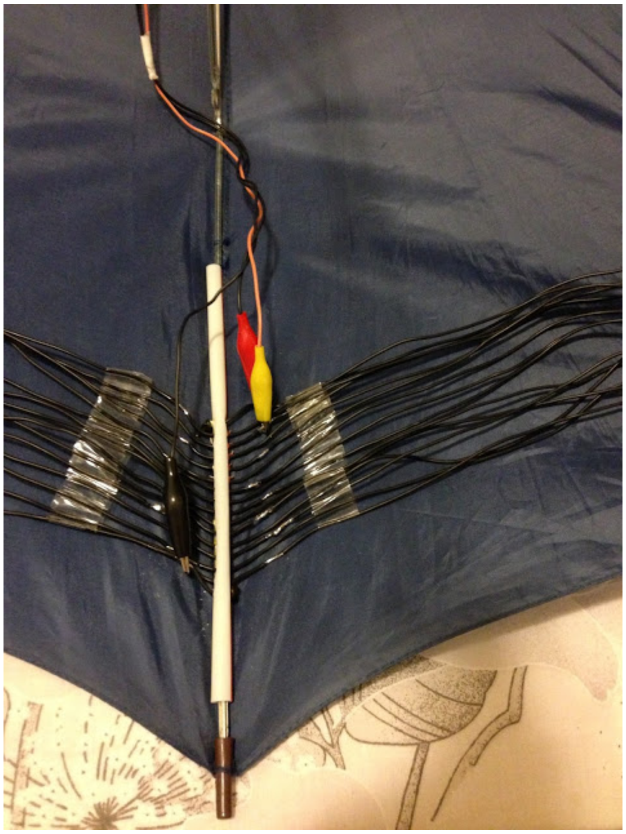
[http://1.bp.blogspot.com/-UjOvv-5nryY/UYU-jk-SEIl/AAAAAAAABGQ/-CWkF9Lt1wM/s1600/IMG_1708.JPG]

Dynamic Views theme. Powered by Blogger.



[http://2.bp.blogspot.com/-fqvkB6WE_QQ/UVmZjX_XpKI/AAAAAAAAA1U/gm6HY_su50w/s1600/IMG_1198.JPG]

5. Create the tabs for the coil for tuning by cutting the insulating rubber of the wire to expose the copper inside. To avoid the adjacent wire touching one another, you can create the tabs of the odd number of turns on the left side, and the even number of turns on the right side. If you have a solder iron, put some solder on to the copper to avoid the stealth covering up the copper again.



[http://1.bp.blogspot.com/-jDdljBxQlWk/UVmb5RZsppI/AAAAAAAAA1g/DBXQnyD2aIl/s1600/IMG_1199.JPG]

The inductance of the completed umbrella coil should be around 300uH, you can measure it if you have an inductance meter. Otherwise, you can determine if you can tune into most of the radios.
If the inductance is too high, i.e. you cannot tune to stations at the high end (towards 1700 Khz) , remove some turns.
If the inductance is too low, i.e. you cannot tune to stations at the low end (towards to 500 Khz) , add some turns.

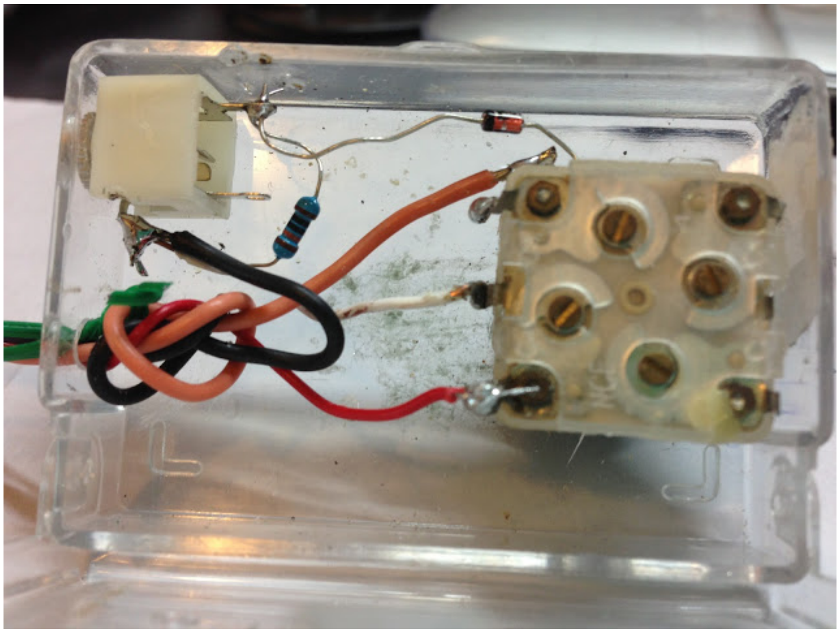
6. To avoid the wires slipping through the openings on the straw, apply some glue there to close the gap.

B. Make the crystal radio (without the coil).

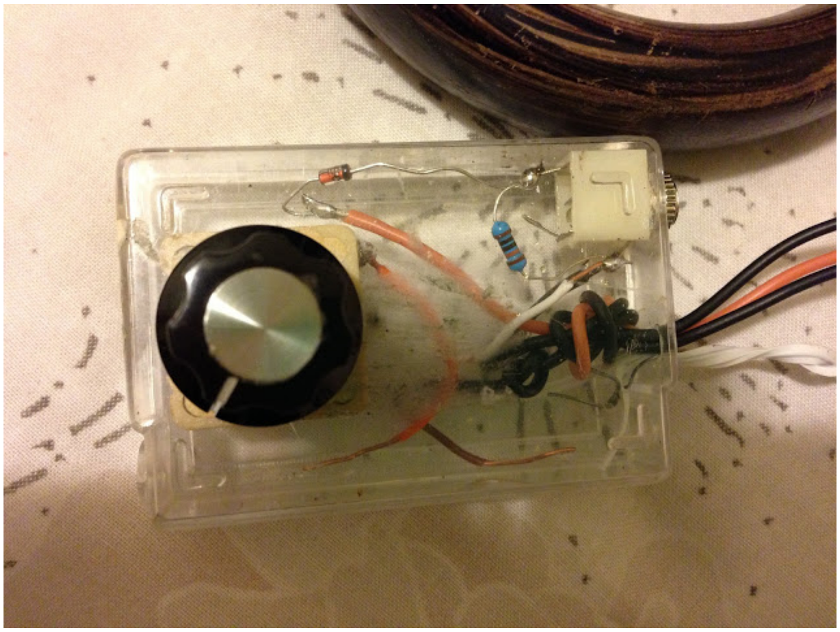
1. Drill holes on the plastic case to fit the earphone jacks, variable capacitor knobs, and one more hole to pass the wires for the crocodile clamps.

2. Mount the earphone jacks and the variable capacitor onto the case and fasten the screws.

3. Refer to the circuit diagram and the real life wiring photo, solder the parts together.
Connect a black wire to the ground of the Jack and connect the other end to a black crocodile clamp.
Connect a red wire to the tip C1 of the variable capacitor.
Connect an orange wire to the diode and connect the other end to a yellow crocodile clamp.



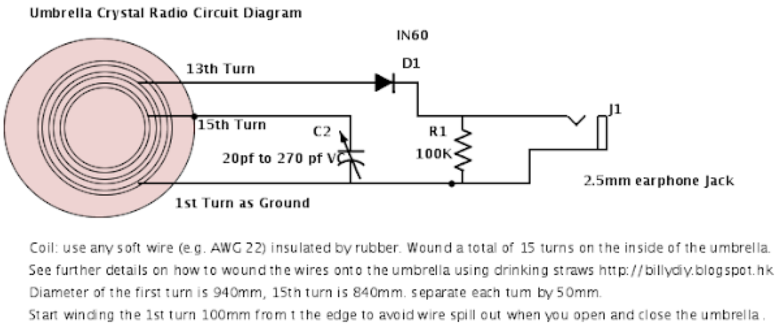
[http://1.bp.blogspot.com/-FsoOXwgYmUI/UV1VCEnXRQI/AAAAAAAAA6Y/76a4H0CYx5Y/s1600/IMG_1260.JPG]



[http://4.bp.blogspot.com/-nygOMUZib2c/UVmffBrMV9I/AAAAAAAAA10/8jQaminvcT8/s1600/IMG_1204.JPG]

C. Put the umbrella antenna and the crystal radio together.

1. Hang the crystal radio from the handle of the umbrella using a piece of wire to tie it.
2. Connect black crocodile clamp from crystal radio (for ground) to the tab of the 1st turn (closest turn to the edge of the umbrella).
3. Connect the red crocodile clamp (for tuning) to the tab of the 15th turn (innermost turn).
4. Connect the yellow crocodile clamp (for detector) to the tab of the 13th turn.
5. Plug a crystal earphone to the earphone jack of the radio.
6. Bring the umbrella down to the street and find an empty space, or get close to the window.
7. This crystal radio does not require an earth, so you can walk freely on the street.
8. Point the umbrella towards the location of the transmitters , or try swing it sideways slowly, and up and down to find the right spot. At the same time turn the knob of the variable capacitor to tune to a station.
9. If you have a wide open space you should be able to tune to a station. Then continue to adjust the angle of the umbrella to find the direction with the best reception.
10. Once you find the best spot, you can try moving the yellow crocodile clamp down to the other tabs to get a louder signal. e.g. Try the 10th Turn or even 7th turn and so on.
11. Some times, the inductance of the umbrella antenna may be too high, you may also want to try moving the RED crocodile clamp down some turns too, e.g. try the 13th turn, or even 10th turn to find the best matching frequency to tune to a station.



Umbrella Crystal Radio Circuit Diagram

Coil: use any soft wire (e.g. AWG 22) insulated by rubber. Wound a total of 15 turns on the inside of the umbrella.
See further details on how to wound the wires onto the umbrella using drinking straws http://billydiy.blogspot.hk
Diameter of the first turn is 940mm, 15th turn is 840mm. separate each turn by 50mm.
Start winding the 1st turn 100mm from t the edge to avoid wire spill out when you open and close the umbrella .

[http://2.bp.blogspot.com/-CJMXABv3a7o/UV1dfnp3f-I/AAAAAAAAA7A/yZsq0oQgq_w/s1600/Screen+Shot+2013-04-04+at+3.58.08+PM.png]

D. Use the umbrella antenna for your existing crystal radio.

1. Hang your existing crystal radio from the handle of the umbrella using a piece of wire to tie it.
2. Using a crocodile clamp, connect the crystal radio's antenna wire to the tab of the 1st turn (outermost turn).
3. If your crystal radio also need an earth connection, connect the wire to earth. Or if you want to try it on the street , hold the earth wire of your crystal radio by your bare hand to create an earth. Or, you can connect the earth wire to some metal poles , fences or benches that touches the ground,
4. Plug a crystal earphone to the earphone jack of the radio.
5. Bring the umbrella down to the street and find an empty space, or get close to the window.
6. Point the umbrella towards the location of the transmitters , or try swing it sideways slowly, and up and down to find the right spot. At the same time turn the knob of the variable capacitor to tune to a station.
7. If you have a wide open space you should be able to tune to a station. Then continue to adjust the angle of the umbrella to find the direction with the best reception.
8. Once you find the best spot, you can try moving the yellow crocodile clamp down to the other tabs to get a louder signal. e.g. Try the 10th Turn or even 7th turn and so on.
9. Some times, the inductance of the umbrella antenna may be too high, you may also want to try moving the RED crocodile clamp down some turns too, e.g. try the 13th turn, or even 10th turn to find the best matching frequency to tune to a station.

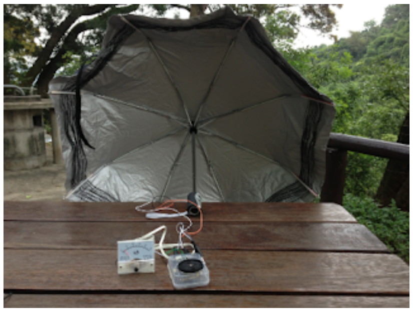
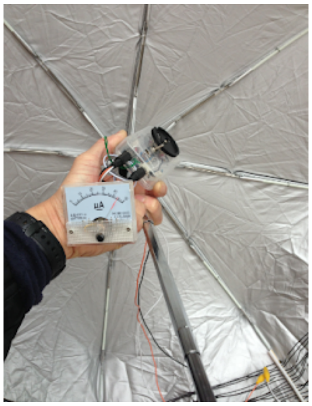
Testing Result

I tested this umbrella radio next to the sea. The radio is very loud. and recorded a record high DC current of 44uA. A regular crystal radio at home will only get around 4uA.



[http://3.bp.blogspot.com/-63NLY_TAJWY/UX09Jhk1paI/AAAAAAAABEY/PsXXPiRoDMU/s1600/Screen+Shot+2013-04-28+at+10.53.12+PM.png]



[http://1.bp.blogspot.com/-BkXGrBIBhiY/UX09LvGfKFI/AAAAAAAABEg/dneyDudJ53Y/s1600/Screen+Shot+2013-04-28+at+10.50.27+PM.png]

What's Next?

I also made this super large golf umbrella radio in much the same way.
Only difference is the umbrella size is 1180mm in diameter.

Délifrance

Hong Kong AM FM Radio Frequencies and Transmitter Locations

Crystal Radios is perfect for AM and recently crystal radio can also cover FM in locations close to the FM transmitting locations, or with FM radio antenna and FM radio signal amplifiers.

Here is a web site that listed all radio broadcast stations in the world.

http://www.asiawaves.net/hong-kong-radio.htm

Radio Broadcast Stations in Hong Kong

The following information is extracted from a web site that listed all radio broadcast stations in the world. Please refer this in detail.

http://www.asiawaves.net/hong-kong-radio.htm

Information below is © Copyright Alan G. Davies 1999-2009, all rights reserved.

I have extracted the info for Hong Kong.

Radio Television Hong Kong (RTHK) [http://www.rthk.org.hk/]

Broadcasting House
30 Broadcast Drive
Kowloon
Hong Kong

Tel: +852 2339 6300
Fax: +852 2336 9314

- RTHK Radio 1: in Cantonese / Mandarin on 92.6-94.4 MHz
- RTHK Radio 2: in Cantonese on 94.8-96.9 MHz

- RTHK Radio 4: in English & Cantonese on 97.6-98.9 MHz
- RTHK Radio 5: in Cantonese / Mandarin on 783 kHz and 92.3, 99.4 & 106.8 MHz
- RTHK Radio 6: relays BBC World Service in English 24h on 675 kHz
- RTHK Radio 7 (Putonghua Channel): in Mandarin on 621 kHz and 100.9 & 103.3 MHz

All networks operate 24h, but some may carry merged programming at times during local evenings and overnight.

Hong Kong Commercial Broadcasting Company Ltd (HKCR) [http://www.crhk.com.hk/]

3 Broadcast Drive
Kowloon
Hong Kong

Tel: +852 2336 5111
Fax: +852 2338 0021

- HKCR CR1 (Supercharged 881): in Cantonese on 88.1-89.5 MHz
- HKCR CR2 (Ultimate 903): in Cantonese on 90.3-92.1 MHz
- AM 864 in English and limited Nepalese on 864 kHz

All networks operate 24h

Metro Broadcast Corporation Ltd [http://www.metroradio.com.hk/]

Basement 2
Site 6, Whampoa Gardens
Hunghom
Kowloon
Hong Kong

Tel: +852 2123 9888
Fax: +852 2123 9877

- Metro Info: in Cantonese on 99.7-102.1 MHz
- Metro Finance: in Cantonese on 102.4-106.3 MHz
- Metro Plus: in English, Mandarin, Filipino, Hindi and Indonesian on 1044 kHz AM Stereo

Mediumwave (AM) Radio Frequencies in Hong Kong

Mediumwave (AM) Radio Frequencies in Hong Kong

Frequency (kHz)	Network	Site	Power (kW)
567 kHz	RTHK3	Golden Hill	20 kW
621 kHz	RTHK Putonghua Channel	Golden Hill	20 kW

DIY Crystal Earphone for Crystal Radios

[http://4.bp.blogspot.com/-W1q6NTSXpuU/UVLilrs6J_I/AAAAAAAAAx0/CAvQFcxXxCg/s1600/Cyrstal+Earphone.png]

What is a Crystal Earphone

Crystal earphone also called Ceramic earphone/earpiece is the soul of crystal radios. They are one of a few types of earphones that are sensitive enough to produce sound from a Crystal Radio. Regular HIFI headphones will not work with a crystal radio. The Crystal radio runs without battery. It runs purely by the radio wave captured by the antenna and convert that into tiny electric current (< 1uA) that is yet sufficient to produce sound through the highly sensitive crystal earphone.

Wikipedia definition of Crystal Earphone [http://en.wikipedia.org/wiki/Crystal_earpiece]

[http://2.bp.blogspot.com/-ALf15x9ipP0/UV0zuFSOrRI/AAAAAAAAA38/Xf4NU5Wtze4/s1600/Screen+Shot+2013-04-04+at+4.02.38+PM.png]

The original crystal earphone (shown above) cannot be purchased in Hong Kong since 10 years ago. You can still buy it from UK through the online shopping sites, e.g. Amazon, or e-Bay, the cost is not too expansive, but the shipping cost alone will kill this idea. The total cost to buy one oversea may exceed HKD 120, for something valued around HKD 30 max.

SPECIFICATIONS of a Crystal Earphone:

- Impedance: 20K ohm
- Capacity: 15,000 pf
- Sensitivity: 57 dB at 1KHz
- Frequency Range: 200 ~ 8000 Hz

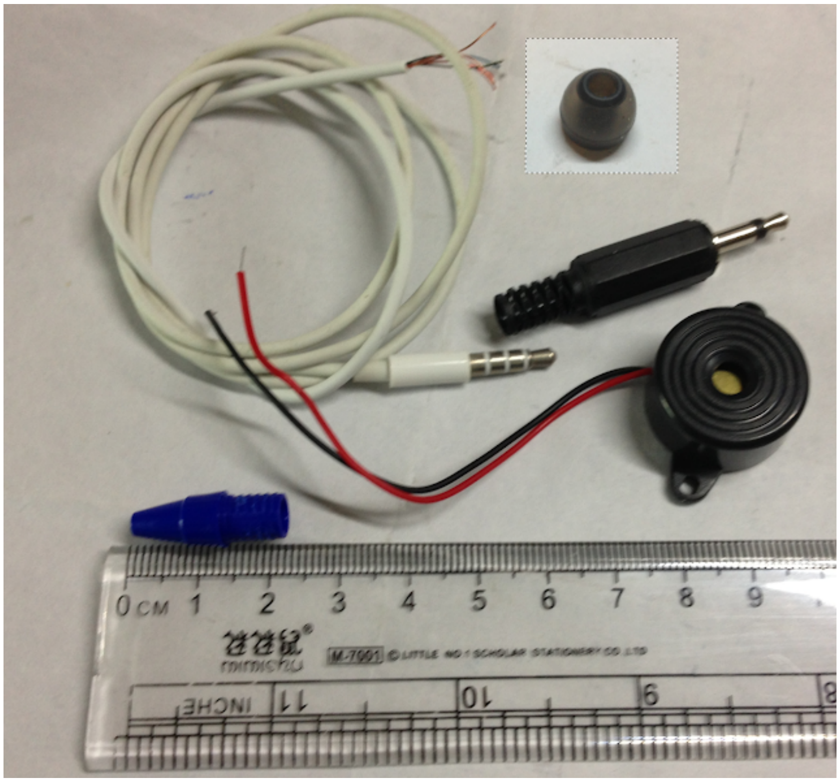
However, with some readily available components you can buy from HK Shamshuipo, Ip Liu Street, you make one yourselves at HKD 10 following the instructions here.

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

Parts you'll need.

1. Piezo-Electric Buzzer (HK$ 7).
2. Cut out 20mm of the tip from a used plastic ball pen (HK$0).

3. A 2.5mm head Jack & wire from a used/broken headphone (HK$0. If you don't have that, you can also buy some spare wires and a 2.5mm mono headphone Jack (the one in black below) (HK$ 3).
4. A rubber earbud cousin from existing earbuds (top right on the picture below).

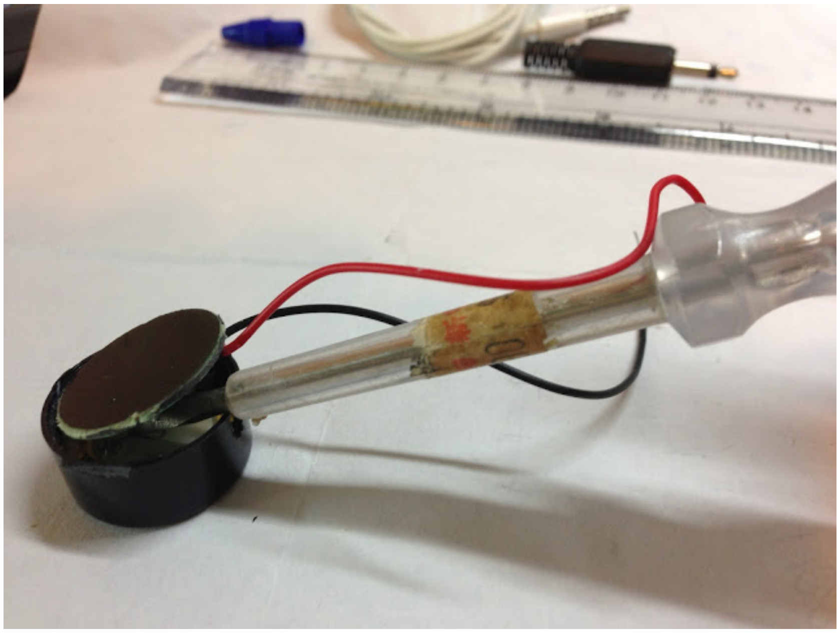


[http://4.bp.blogspot.com/-W5ExpIIP2L0/UV1aUnwMazI/AAAAAAAAA6o/Hk0QoJe3pyQ/s1600/Screen+Shot+2013-04-04+at+6.46.24+PM.png]

How to make it.

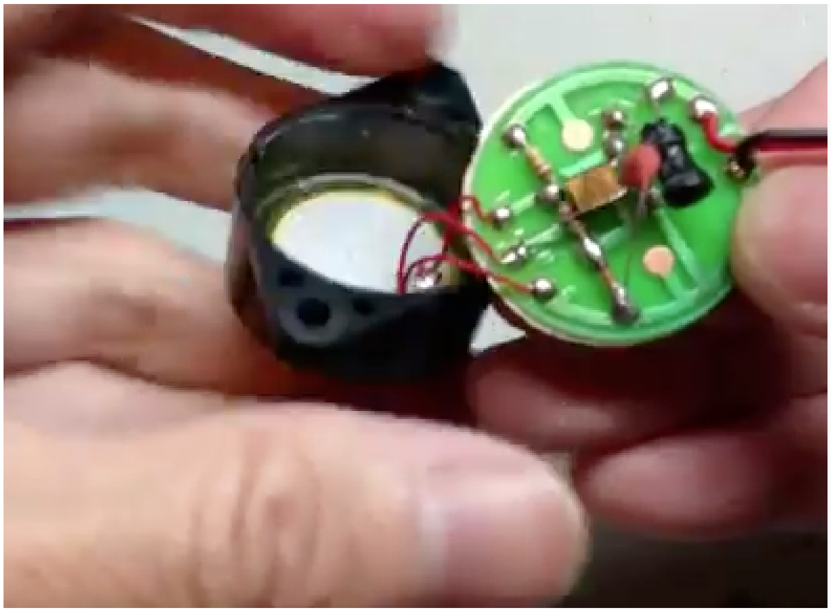
Watch this video or follow the instructions below:
http://www.youtube.com/watch?v=DjCKVAMJGlo [http://www.youtube.com/watch?v=DjCKVAMJGlo]

1. Using a screwdriver and brutal force, remove the lid of the buzzer



[http://4.bp.blogspot.com/-7mKdE9pSAKE/UV1U9zeAK8I/AAAAAAAAA5M/BoCX_P18bT8/s1600/IMG_1246.JPG]

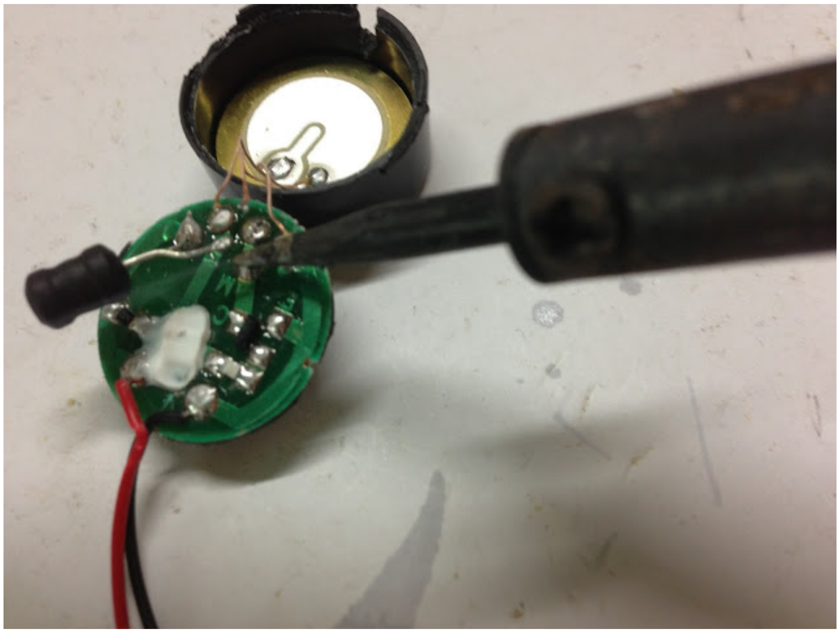
2. Find the Piezo-electric plate (the circle plate in gold and white and the circular circuit board with some other electronic components.



[http://2.bp.blogspot.com/-ZhHrjOlicT4/UV03KsrjOCI/AAAAAAAAA4M/iAA0YXY_9N8/s1600/Screen+Shot+2013-04-04+at+4.17.13+PM.png]

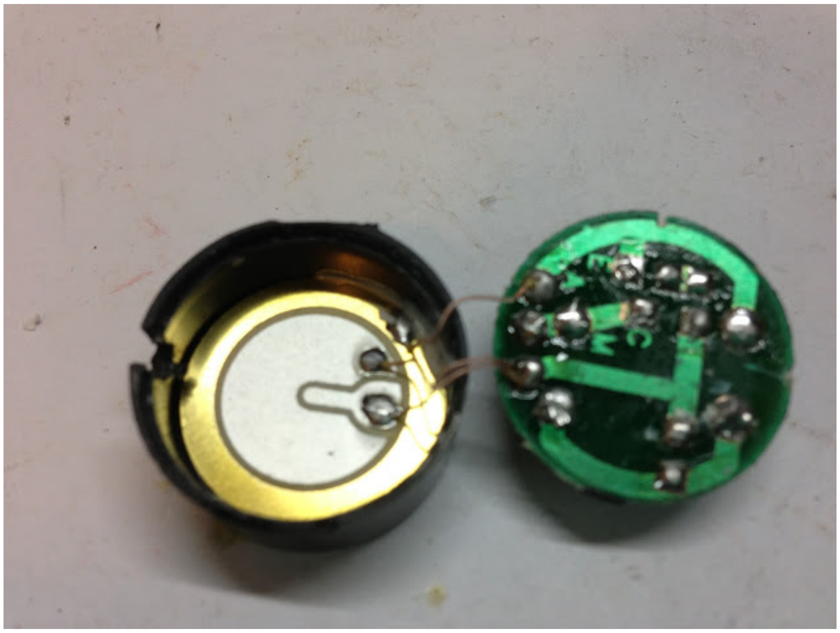
3. Remove all other electronic components using a solder iron and a clamp; as these components will reduce the impedance and also lower the audio output of the crystal earphone we are going to make.

Dynamic Views theme. Powered by Blogger.



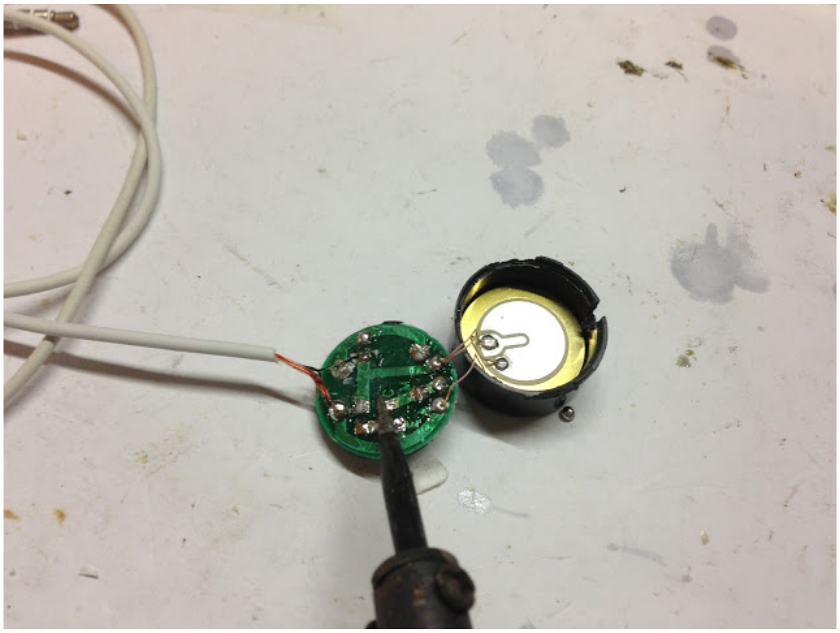
[http://4.bp.blogspot.com/-u4SR5E_5NRI/UV1U91sn2hI/AAAAAAAAA5A/vlQichGwxCw/s1600/IMG_1248.JPG]

This is how it looks after all the unnecessary electronic components have been removed from the circuit board.



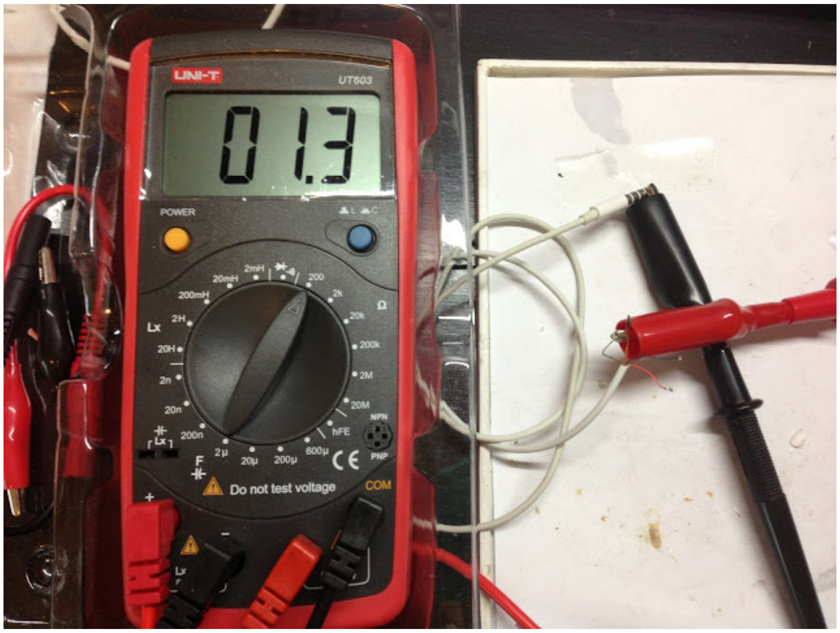
[http://1.bp.blogspot.com/-uC2t2vpXUus/UV1U-kz9wol/AAAAAAAAA5g/UKrFKi_8s9c/s1600/IMG_1251.JPG]

4. Using a solder iron, connect two wires from the earphone jack directly onto the two points on the plate. One wire touching the circumference (gold), a second wire touching the inner plate (white). There may be a third white plate which is smaller, connect the wire from there to the other bigger white plate to get maximum audio output. Polarity is not important. So, you can choose which wire to go where.



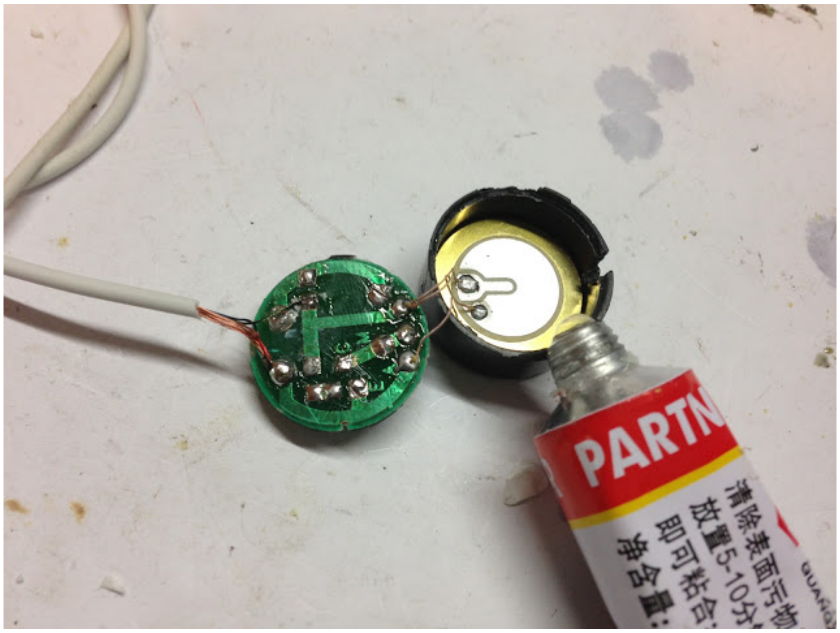
[http://3.bp.blogspot.com/-PqnLtCqYJ14/UV1U_ScG6vI/AAAAAAAAA5k/6vlkYKsyf-Y/s1600/IMG_1253.JPG]

5. If you are using a separate earphone jack, connect the other end of the wire to an 2.5mm mono headphone jack.
6. Before you close the lid, test the connections it by shorting the terminals of the jack together using a screw driver or touching the tip and the base of the earphone jack with a multimeter set to Ohm-meter. You should hear some "click" sounds each time you shorten the terminals of the jack.



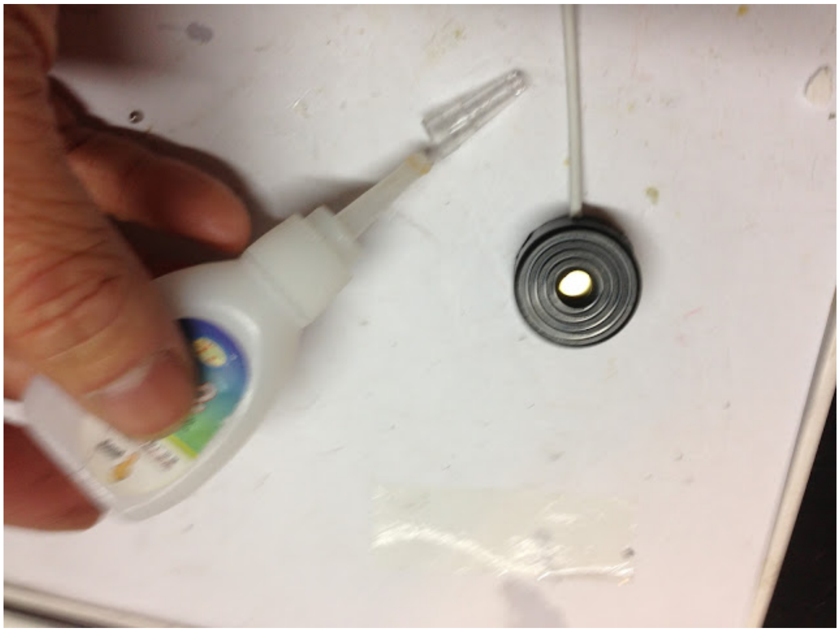
[http://2.bp.blogspot.com/-f8bHtWE-d1Q/UV1U-4AXTNI/AAAAAAAAA5c/IP9i34Ay-u4/s1600/IMG_1252.JPG]

7. Close the lid and secure it by applying glue. Do not use the strong instant super glue. Use some regular glue so can still open up the lid later for maintenance in case the wire inside is broken.



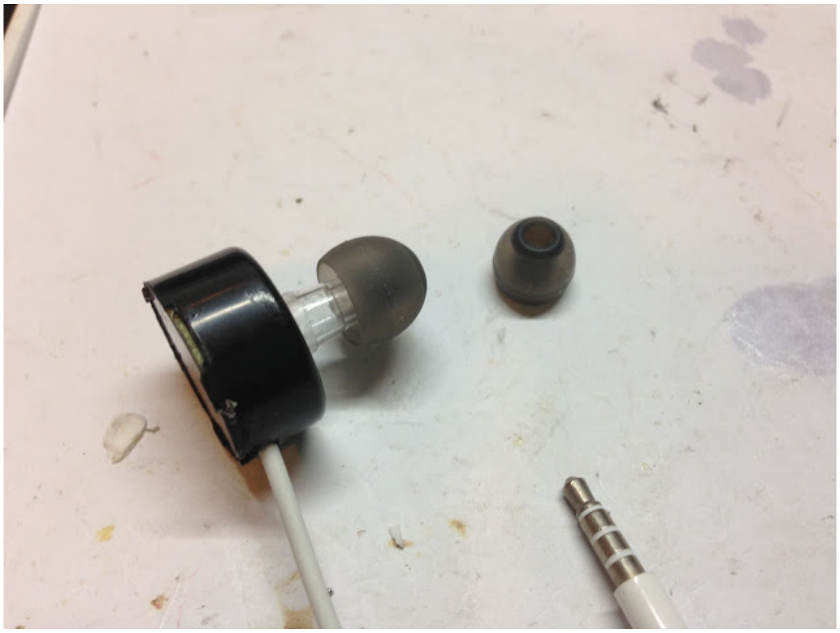
[http://4.bp.blogspot.com/-AhGlmtzQ604/UV1U_63a5WI/AAAAAAAAA6A/vWaW7oQGpBI/s1600/IMG_1254.JPG]

8. Line up the hole from the tip of the ball pen to onto the hole in front of the buzzer. Stick them together using instant super glue. The function of the ball pen tip is to focus the sound to the ear.



[http://3.bp.blogspot.com/-Dj7lCuYkL-Y/UV1U_3tn3tI/AAAAAAAAA5s/2ypnc_nQy_o/s1600/IMG_1255.JPG]

9. Attach the earbud cousin to the tip of the pen.



[http://3.bp.blogspot.com/-dYJDvrIR8hc/UV1VANPrc8I/AAAAAAAAA54/1TCHuDQzlOU/s1600/IMG_1256.JPG]

10. Connect it to your Crystal Radio to test.

[http://www.blogger.com/blogger.g?blogID=2311644141825422235]

[http://2.bp.blogspot.com/-FYzx5aqFfVM/UVGOaN0HeBI/AAAAAAAAAxQ/XQtWPgoL_VQ/s1600/IMG_1098

Parts you'll need

1. Variable Capacitor 360 pf - from an old radio.
2. Coil wound on a Ferrite Powder Rod - from an old radio e.g. old Walkman
3. A Crystal Earphone or a PC speaker with builtin amplifier.
4. Germanium Diode IN60
5. Resistor 100 Kohm
6. 3.5mm earphone jack
7. A small plastic box,
8. some wires .
9. Solder iron.
10. Antenna - 20 meters hanging vertically or horizontally at a high location (Warning : Lightning Hazard)
11. Ground - connect a wire to your metal water pipe.

[http://www.blogger.com/blogger.g?blogID=2311644141825422235]

[http://4.bp.blogspot.com/-QqxK3OffVq4/UVLe8yWkFzI/AAAAAAAAAxo/4vtNVM1EUMY/s1600/parts.png]

You can get most of these from electronic ships in Shamshupo, except parts #1,2 & 3.
For the variable capacitor and the coil you can easily buy some old recycled walkman or old radios for HKD20-50 from the hawkers in Ip Liu Street in Sham Shui Po. The other way is to go to taobao.com to buy them online and ship to HK. The goods is RMB 5, but the shipping fees is minimum RMD 30, so not worth it unless you buy in great quantity.
For the Crystal Earphone, it's very hard to buy nowadays. Refer to my other post to make one yourselves. DIY Crystal Earphone for Crystal Radios [http://billydiy.blogspot.com/2013/03/build-crystal-earphone-for-crystal.html]

Remember to leave me some comments (at the comment box) at the bottom of this if you have read this blog.

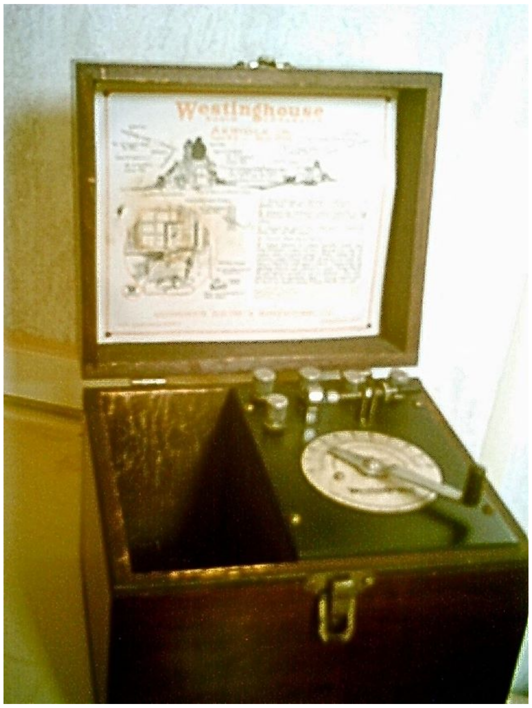
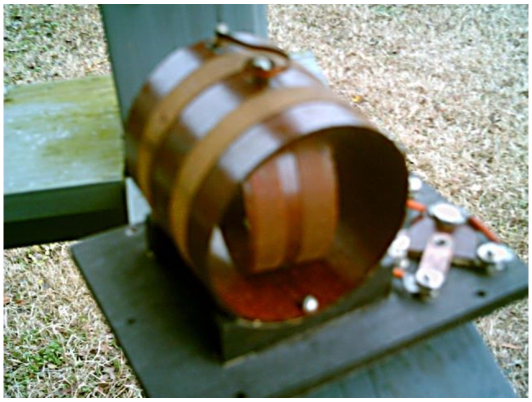
Radios Of The 2010 First Final Farewell DX Contest
Contest Entrants

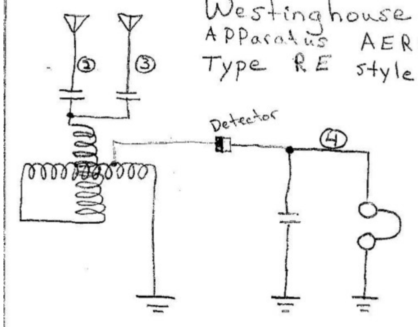
Page 3

Sean Whiteacre, Hobby Class Entry





Westinghouse Radio
Apparatus AERIOLA, JR
Type RE style 307421



Made in June of 1921

② This post is for Stations Below 350 meters

③ This post is for Stations between 350 to 500 meters

④ Terminal 4 for headphones

The Antenna taps are for
Selecting the frequency
coverage of the radio
not for tuning the
radio for better reception.

The radio is a Westinghouse Aeriola, Jr. I did not use a regular diode, but the real detector on the radio. The "Perikon" detector uses two rather rare minerals; Bornite in the fixed cup and Zincite in the movable section. Anyways I used the Perikon Detector. I also used the original 1921 C.Brandes Superior headphones from 1921.. Antenna was 25 ft in air and 150 ft long, Inverted L type.

Kevin Norton, Open Class, Loop Class and Active Device Class

I used the K-3 Big Litz Dx Set for the Open Class. It was the same set up as last year. For the Loop Class, I used a low Q loop built on cardboard box.

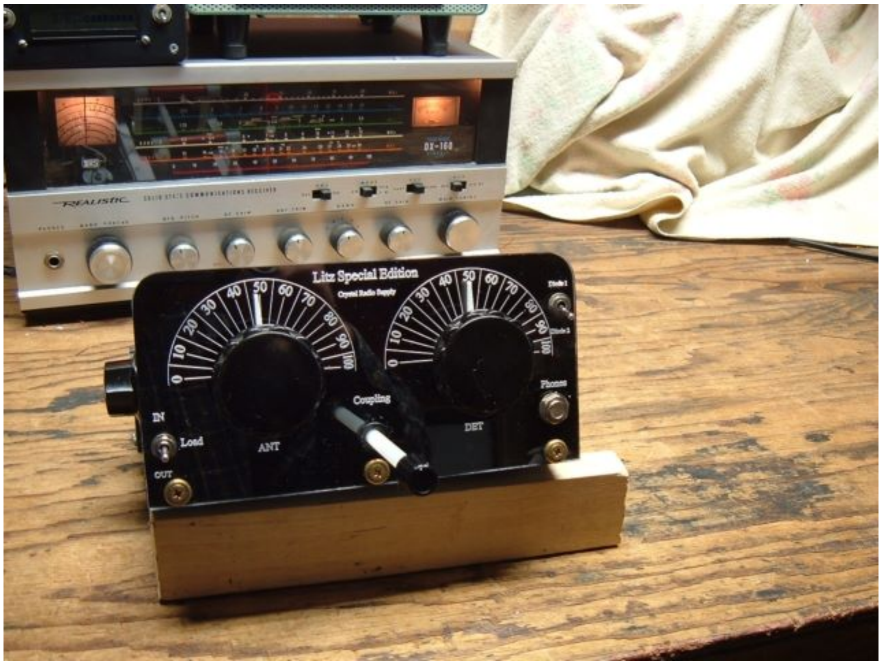
The Active Device Class entry was a WN6Q MPF-102 Regen (Via Owen Poole). I originally tried this as a double tuned set using 2x 660/46 ferrite assisted air coils, 4 gang ceramic wiperless variable caps, and a Litz air tickler. The regen set worked well, but was very hard to line up and very touchy. When the antenna tank was removed the set worked MUCH better! It still WAS a regen, and therefore still had a few flukes. It was MUCH more tamed, and Dxing became much easier.

The sets radiation was read off of my Icom R-70, so digital spotting was a snap. The final version was a single tuned tank of a ferrite assisted air coil, a 4 gang ceramic wiperless and crystal earphones in parallel. The antenna was VERY lightly coupled via a few insulated turns of a gimmick capacitor. At times, I could zero beat the set simply by turning my head a bit to one side!

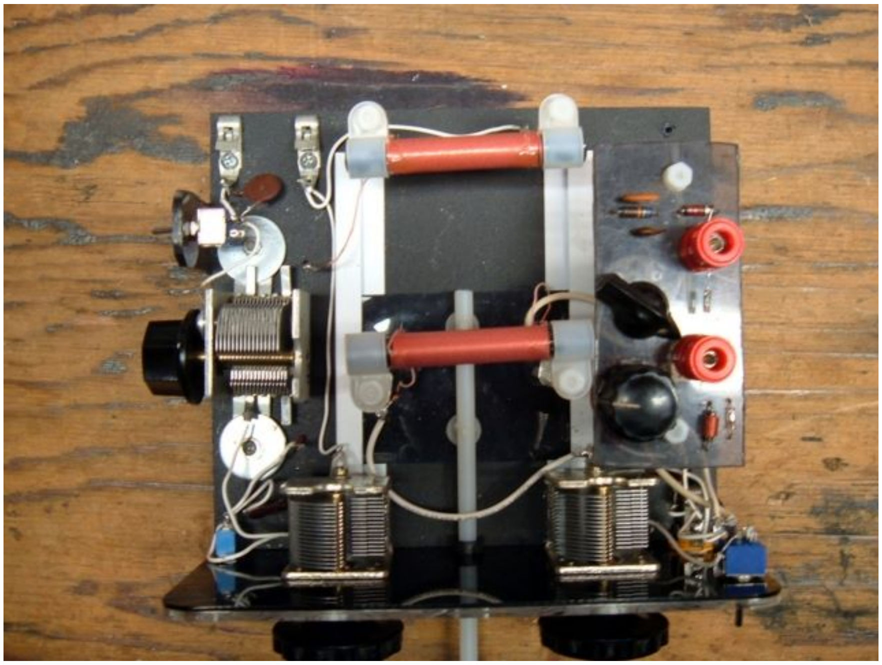
I copied SOMETHING (anything from beat notes to ear splitting locals) on nearly EVERY frequency out of the 119 channels. Maybe 90 stations or more of at least very weak audio or better.

FWIW, I made a big boo-boo and left the set in place during a vicious white out snow squall. We had very high winds and blizzard type of snowfall rates. The antenna kept discharging arcs every 5 or 10 seconds. They could be heard in the next room. By the time I realized what was going on, it was too late. I pulled the antenna line off and measured the arcs, which by that time were down to around 3/4". To fry the set in the position it was in, they had to have been at around TWO inches (30 Kv??) to bypass the gimmick cap twists and leap to the set. Needless to say, a new FET had to be installed. Live and learn.

Glen Yarbro, Open Class



Litz Special Edition
Crystal Radio Supply
Diode 1
Diode 2
Phones
Coupling
IN
Load
OUT
ANT
DET
REALISTIC
DX-160



The set used was a Litz Special, modified to Dave Schmarder's #44 wiring configuration. The antenna was 250 feet long and 30 feet high. The ground consisted of two 8 foot ground rods.

The set used an 1N34A diode and 4K Navy hadphones. No wave traps were used. The spotter radio was a Realistic DX-60 with a frequency counter.

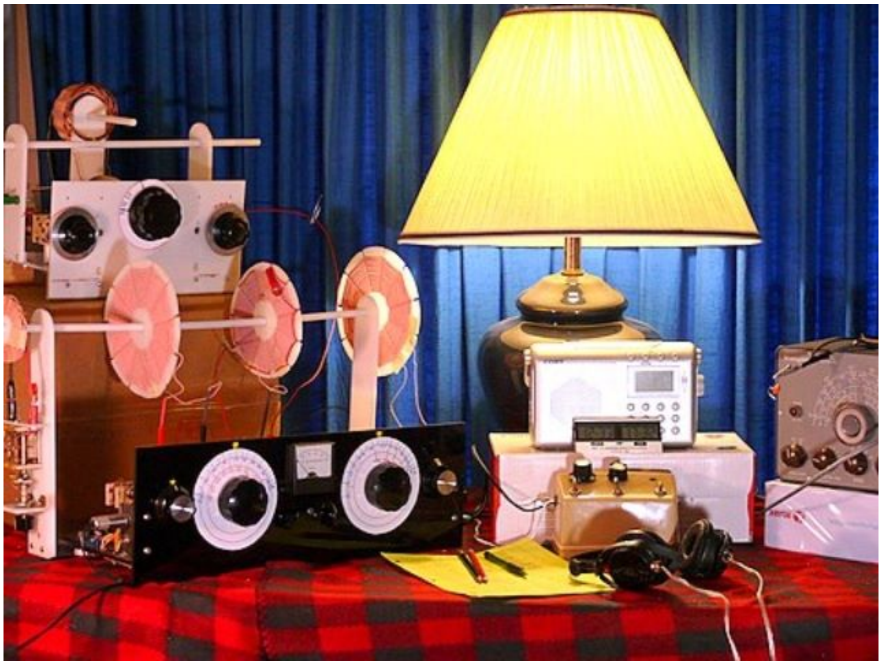
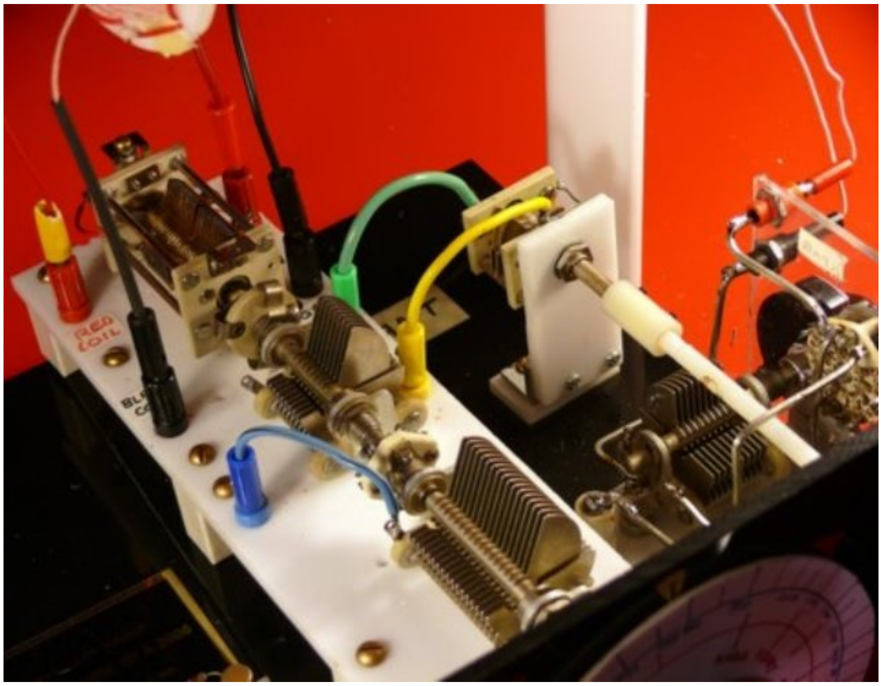
Radios Of The 2010 First Final Farewell DX Contest Contest Entrants

Page 2

O. T. Anderson, Open Class Entry



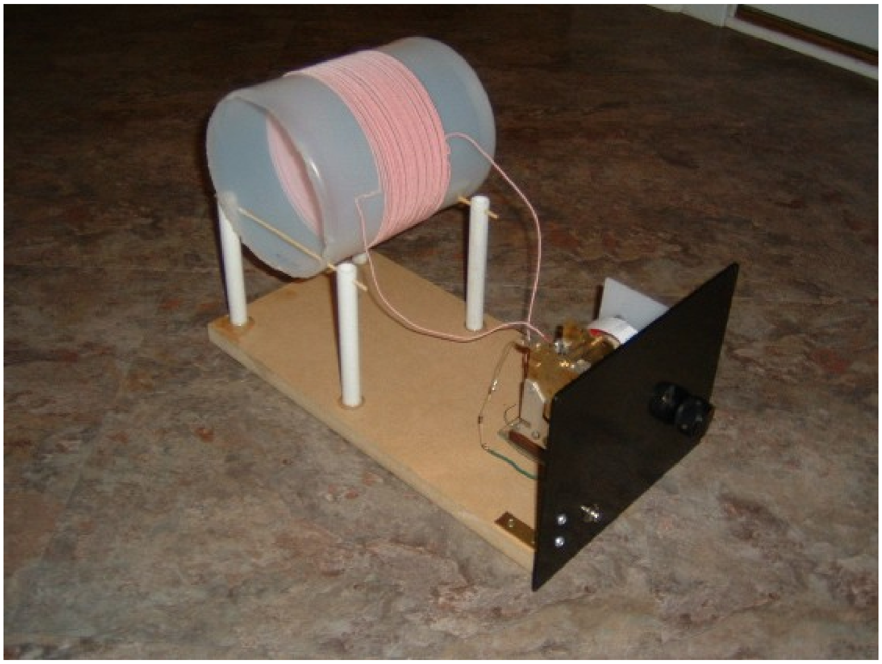


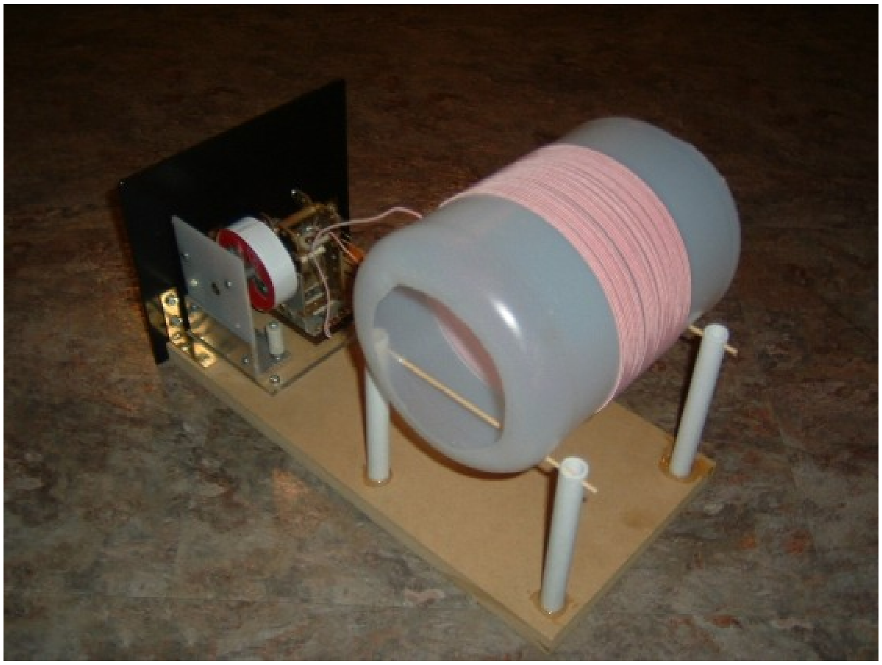
This the same crystal set I used last year with a few revisions. I had 66 stations last year and my goal was to double it. The Mexican stations come in good in Oklahoma.

This crystal set is the same as last year with 3-4 updates.. The extra coils are wave traps for knocking out that KFAQ, 50,000 watts, in sight of our house. Also another 50K across the town. Up high is a new wave trap with silver caps. It will tune any local station. The pictures also shows a "Drug Store" spotter and a Knight Sig Generator. The two dials show the freqs and also spots several local stations. The right dial has another calibration, one is the 1700 to 530 freqs, the other calibrations is the high end freqs when using only the 140 mmfd condenser, about 1750kcs to 1000 kcs. Lots of band spread.

The other picture is the RF section with a silver cap at the far end. It tunes the antenna. The small var cap with the nearest blue wire connects the 2 nearest caps for all the freq 1700 to 540, normal use. With the blue wire not connected we use only the 140 mmfd cap, tuning about 1750 to 1000. This gives good band spread at the high end. The blue and yellow wires connect a 15 mmfd var cap, helps to "rock" in a distant station. If I good get rid of that terrible KFAQ signal things would be a lot better.

Jack Bryant, Open Class Entry

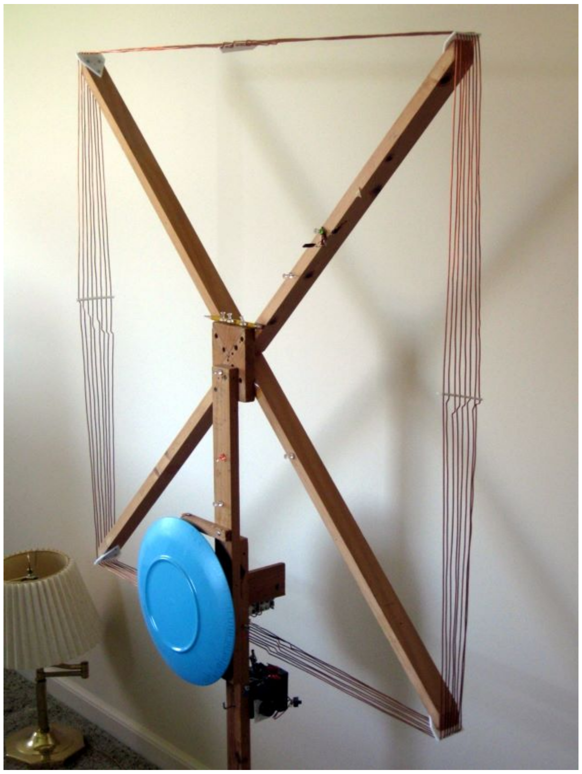


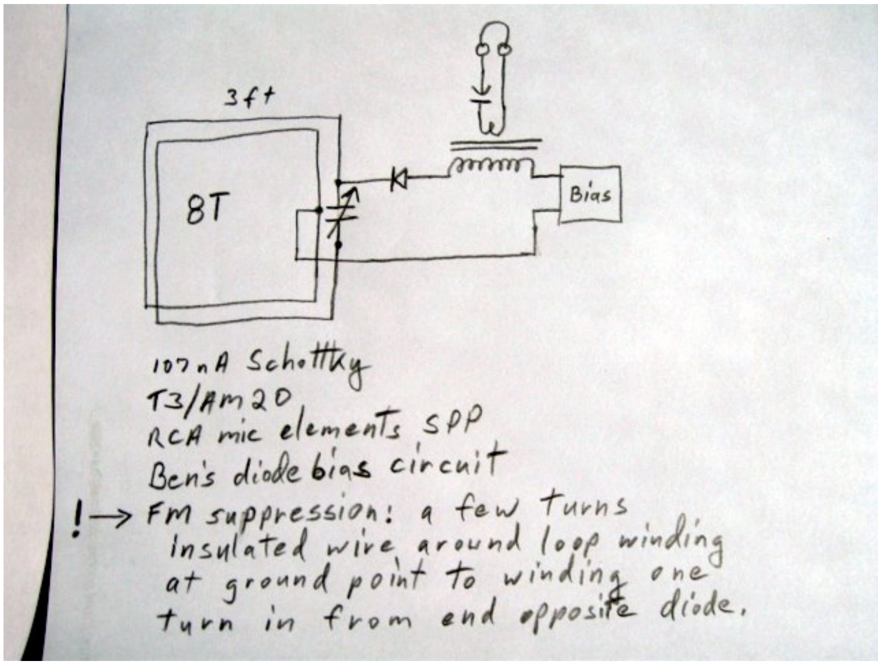


I only worked the last week of the contest, focusing on the broadcast band. I used essentially the same set for that I used in years past.

I have used a Realistic DX-398 for several previous contests, and I used it for this one, too. I used a PC for logging along with paper copy backup. I used a four foot table from Lowe's as my listening post.

Garry Nichols, Loop Entry





107nA Schottky
T3/AM20
RCA mic elements SPP
Ben's diode bias circuit
!→ FM suppression: a few turns insulated wire around loop winding at ground point to winding one turn in from end opposite diode.

(Note from Jack: don't you just love the back of the envelope schematic! A wise sage at work use to say that if a detailed study didn't agree with the broadbrush, back of the envelope calculations, then the detailed study was probably wrong!)

A few changes for my loop this year:

1) Turns spreaders at the midpoints of the frame tightened things up and stopped rattling wire. Don't know why I didn't do this sooner!

2) I seriously reduced my troublesome FM interference with a simple trick. Somehow I noticed that a few pF across some of the loop turns seemed to reduce it. So I experimented first with a tiny variable (which turned out to have too many pF even fully open) and then with a small length of thin teflon insulated wire. The best positioning was from the exact center of the total winding across a few turns to a position one turn in from the end of the winding opposite the diode. I put it there to possibly help balance the loop because I use the other half of the winding for the detector. A few turns of the wire around each winding did the trick.

The upper half of the BCB used to be plagued by FM. It was difficult to tell if I was hearing a weak AM station or FM interference unless I spent some time listening. A real pain! My mod suppressed interference on the upper half and I can only hear FM if I tune above 1700. A lucky break after on and off problems for years!

3) I tried Ben's diode bias circuit this year along with my favorite 107 nA Schottky diode. I had to bias the diode, so that it appeared to have a higher saturation current. A bit more, lower in the BCB, and a bit less near the top. Fits theory pretty well! I used only the T3/AM20 transformer on my RCA mic elements to avoid possible problems with the Select-To-Match circuit and the bias circuit not getting along. How best to hook the two up left some doubt. For my setup, I could never decide if the STM was better than the T3/AM20 alone anyway.

Dan McGillis, Open Class Entry and Active Device Entry

I used two radios in the 1/15/10 contest.

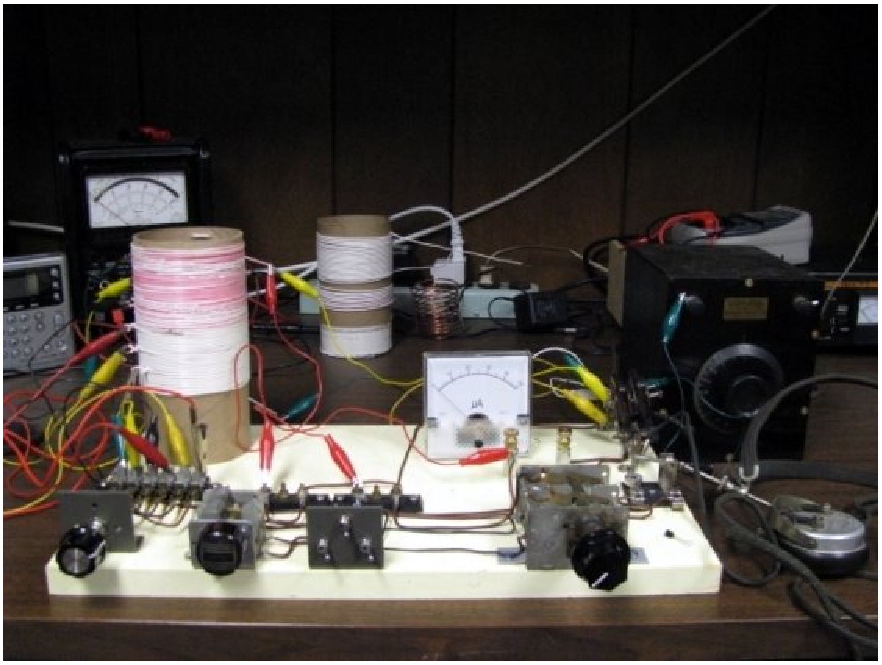
For the BCB Crystal radio section, I used a simple double tuned Mystery set made with dual-gang capacitors from Leeds Radio and ferrite rods wound with 165/46 litz. It's described here.

It was a very good daytime performer, but only a fair night time DX catcher. The bandwidth was just a bit too wide for all the strong DX stations and the digital hash which now seems to be everywhere at night. Still, it's a nice loud little radio.

For the active device section, I used a 2-JFET Regen plus an op-amp audio amplifier with an active bandpass filter. My primary goal was to be able to copy Morse code (CW) in the 40 meter ham band (7 MHz). The radio is described here.

The performance of this simple set-up really surprised me. It's an excellent CW receiver -- stable, quiet, sensitive, and selective. Excellent for SSB and AM too. A real keeper. I even managed to make some 2-way contacts on 40m using this receiver and about 3 watts of transmitting power. That was a lot of fun.

Jerry Walker, Open Class Entry



-The crystal set used was double tuned.

-The antenna was a 75 ft long wire.

Due to a dispute with a former landlord (NOT related to the radio), I lost my previous office, radio loft, and 5 story high, 115 foot long-wire antenna for this year's contest. I also used the same mediocre "throw together" 100/46 Litz wire dual-tuned set that I whipped up last year. I still used my simple Bogen T-725 transformer driving a pair of 1925 vintage Western Electric 509-W headphones. I had to run it all off a long-wire antenna only 20 feet or less off the ground, bent around all over the place to fit my back yard.

Strangely, this year the radio seemed to work FAR better with the antenna (series) matching capacitor moved from the antenna line above the ATU tank, to the ground wire BELOW the ATU tank; most likely due to the vast differences between to two antenna sites used with the set in 2008 and 2009. This gives further evidence of how two different builders with two basically identical sets have been getting different results as to where to put the ATU series capacitor. With the same radio, radically DIFFERENT results, depending on the antenna used).

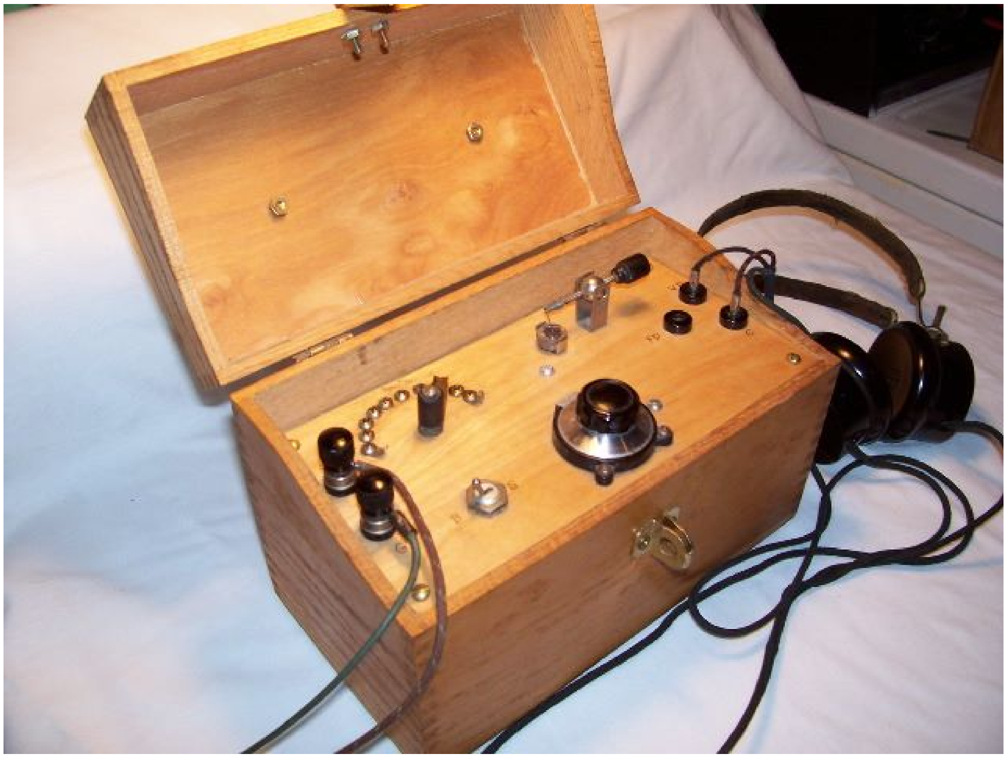
My only other change was the replacement of the approximately 46K fixed resistor in my "Benny" with a 250K audio taper pot - a noticeable improvement.

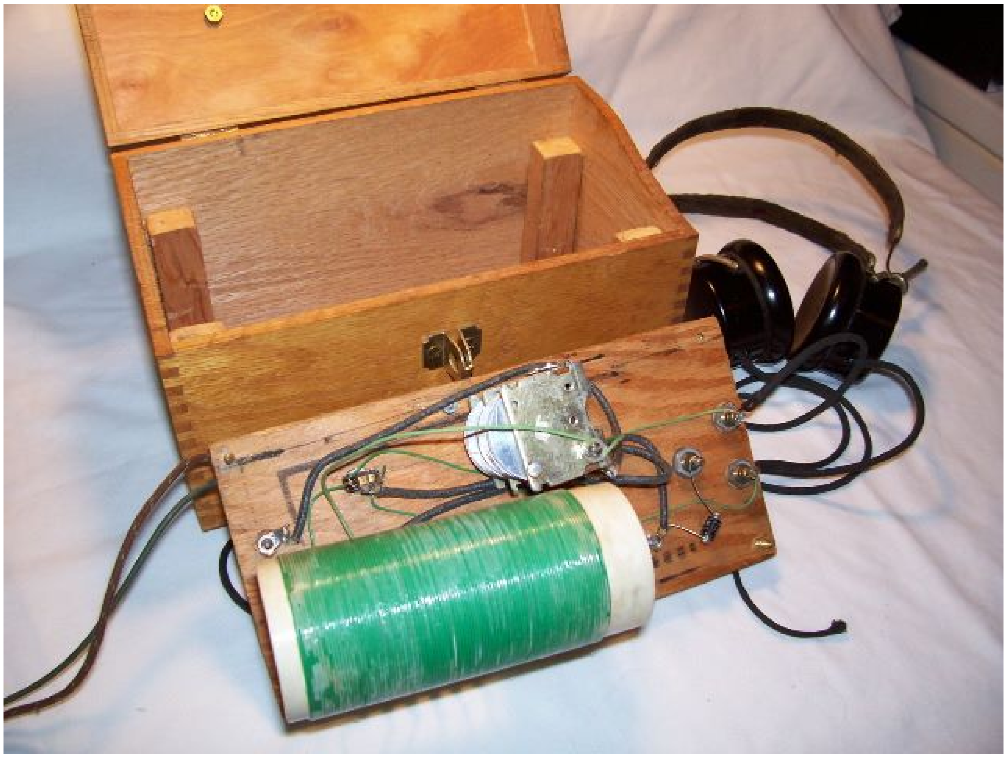
I assumed the set performance would be much worse overall than last year, but I was pleasantly surprised. Although it did have poorer overall reception of New England area stations, it did as well or BETTER on DX. In fact, I raised my total station count this year from 62 to 68 stations, with fewer of them being locals (Nashville was my furthest hit, I believe). It raised my points from 42,000 to over 64,000 - a 50% increase. I attribute this to the fact that this is my second contest.

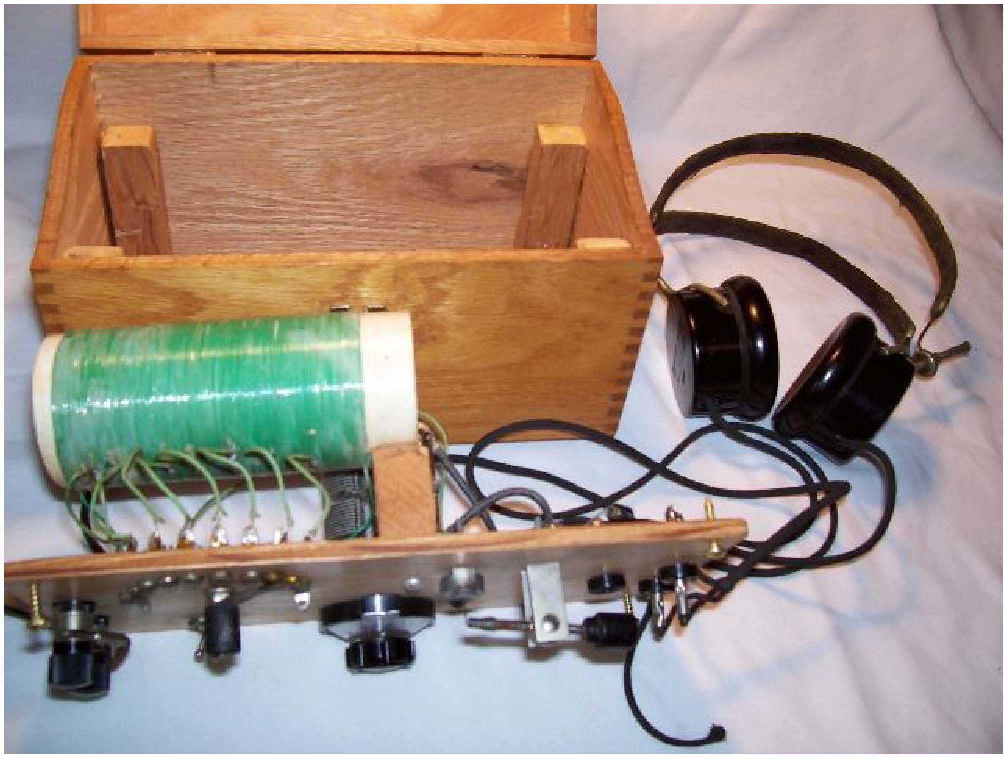
I am getting more capable with the "spotter radio" in identification of stations, as well as hunting stations down on the Crystal Set after first isolating them with the spotter. Hopefully for next year I will have a 660/46 Litz “dream set” hooked up to a nice set of SP phones and a decent 30 foot high, 50 foot long 4-wire flat top antenna squeezed into my yard. My overall goal is fairly modest. Massachusetts is notoriously BAD for crystal radio DX. The glaciers in the last ice age pushed billions of tons of our topsoil down into the Atlantic Ocean south of Connecticut. As a result of this, we have poorer and less efficient grounds than other regions.

Assuming a 450 mile average maximum DX "listening circle" for the average set, over half of MY circle here in coastal Massachusetts is to my east, over the wide open empty ocean. If I can ever manage to break a 100 station level count, I will consider that winning my own personal gold medal!

James D Fletcher, Hobby Class







I built the MRL No. 2A "Long Distance Crystal Set" from plans I got from Mr. Elmer G. Osterhoudt. I used parts from what I had on hand and wound the coil on PVC pipe. This was in 1979 and my oldest son was 10 years old, so this was a project we worked on together and gave him some practical experience he still uses today.

I put the works in a 8" x 5" oak file box that office supply stores used to sell. I use a type "C" Baldwin headset that really makes a difference compared to regular headsets. This is the same set that I used in the 2008 Contest.

Click here to go to my website and see what I did this year:

-Single 7C5 Loctal tube regenerative radio with 6 volt filament and 25 volts DC plate

-Two tuned circuits using toroidal forms. Single tuning control

-Sound powered headphones

-Antenna, 40 meter wire up 3 - 4 meters running east to west.

Robert Weaver, Active Device Class

This year, I have two different active device receiver entries. One is a direct conversion receiver using a sheet beam tube, that I built two years ago, and used in the Radioboard summer DX contest in 2008, but never in this contest. Shortly after I built it, I built a sheet beam superhet receiver and the direct conversion receiver was mostly forgotten. I wanted to dust it off, make a few improvements and enter it in another contest. It took a while to get to it. So, I began the contest using the same superhet that I entered last year. That receiver is completely unchanged, and you can find a description of it under the 2009 entries, or see the writeup on my webpage.

The direct conversion receiver has a tuned front end to help reduce interference from strong local stations and out of band signals. The signal enters the control grid and is mixed with the oscillator signal which appears on the deflectors. The result is an audio signal which appears as a differential signal on the plates. This audio signal drives the push pull primary of the interstage audio transformer. The secondary is connected back to the control grid in series with the incoming RF so that it is amplified reflex style. The resulting amplified audio is now a common mode (in-phase signal) at the plates, and so has no effect on the interstage transformer, and passes through the primary winding and on to the output transformer which is in series. The secondary of the output transformer drives the headphones.

Feedback for the local oscillator is taken differentially from the plates, through an audio blocking capacitor to the primary of the oscillator coil. One half of the secondary of the oscillator coil forms a tuned circuit with one gang of the variable capacitor. This side of the secondary drives one deflector, and the other half of the secondary produces an opposite phase signal to drive the other deflector. This oscillator is very stable and is almost completely immune to pulling towards the incoming RF. In fact this is a bit of a disadvantage, because it makes it very touchy tuning in AM signals without getting a beat frequency.

In the first version of this receiver, I had included feedback from the cathode to a one turn tickler on the RF coil, to provide a small amount of regeneration. However, after making a number of modifications and tests, I finally concluded that there was little to no benefit. So, I finally removed it. A description of the receiver is here.

There is a DPDT switch which reverses the phase of the interstage transformer secondary. This is to correct for slight unbalances in the tube which could cause oscillation when the volume control is turned all the way up. There is a bit of phase shift that varies across the band, and so the best position of the switch changes at different frequencies. I had tried various other plate balancing techniques (such as in my superhet receiver) but found that nothing worked as well as the reversing switch.

The receiver worked reasonably well. It was built as an experiment to see what could be done with a sheet beam tube. If you read the write up on my website, I sounded much more enthusiastic right after I built it. However, nearly two years later, and having built a better receiver in the interim, I find that listening to AM for any length of time on this set can be tiresome with the touchy tuning and almost constant beat tone. So, after using it for a couple of days and logging a respectable number of stations, I retired it and switched back to the superhet which outperforms it in almost every respect.

It seems that each year, I manage to learn a new trick or two. This year, I connected a set of wavetraps between my loop antenna pickup coil and the receiver. I wasn't sure how wall wavetraps would work with the loop. But, using the antenna orientation to null out a local station on 860kHz, and then using two of the wavetraps tuned to the same frequency to further null it out, I was able to log my first station ever on 870 kHz: WWL New Orleans, which by the distance/power formula was my second best catch of the contest. My best catch was KVNS 880, Brownsville TX. Attempts to log a MW station outside of North America have failed so far. Hopefully, one of these days it will happen.

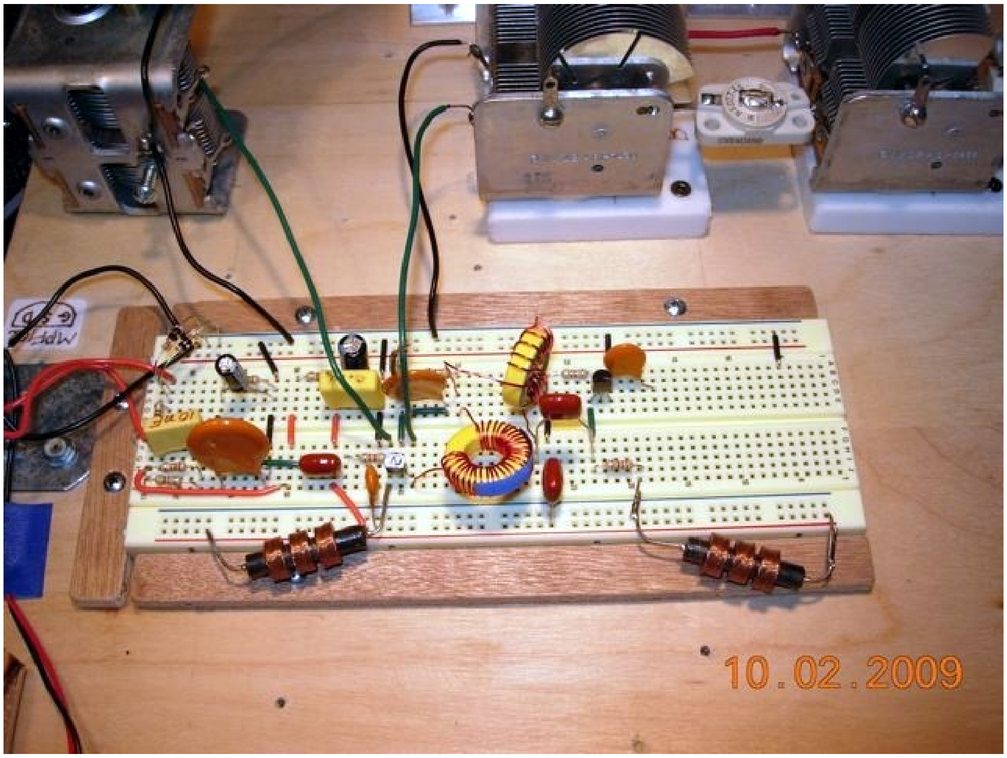
Crystal Radios Of The 2009 Contest Entrants

Page 5

Dan McGillis, SW Class (regen set)

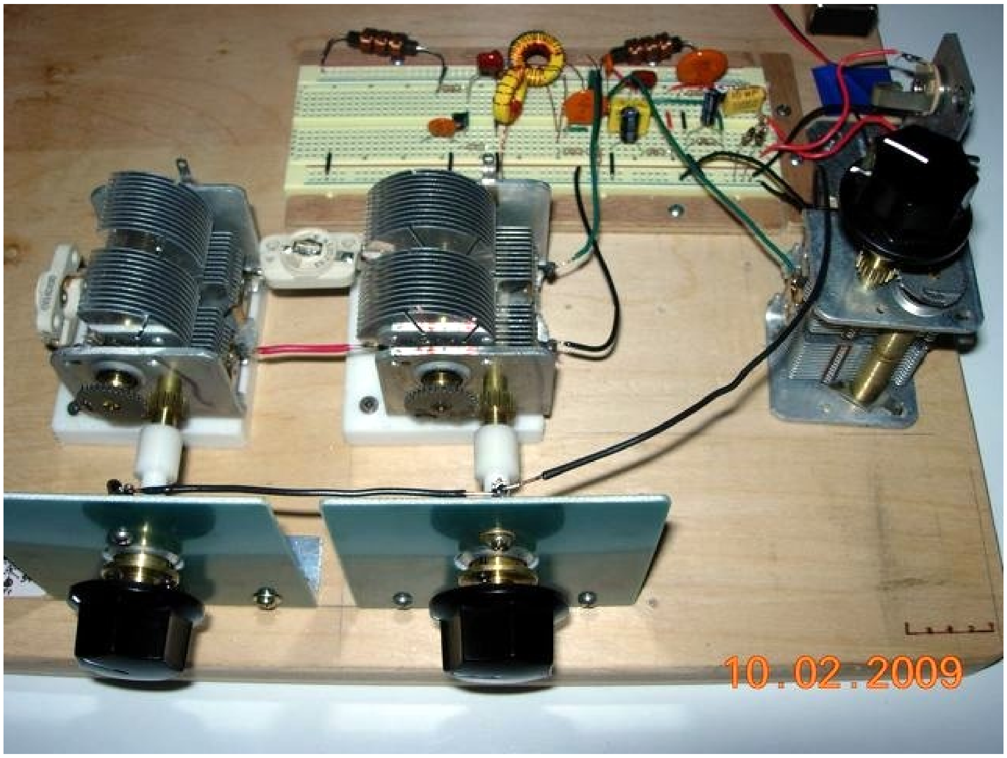


Thanks again for letting me enter my SW regen (with it's Radio Shack amplified speaker) in the '09 Sprint contest.

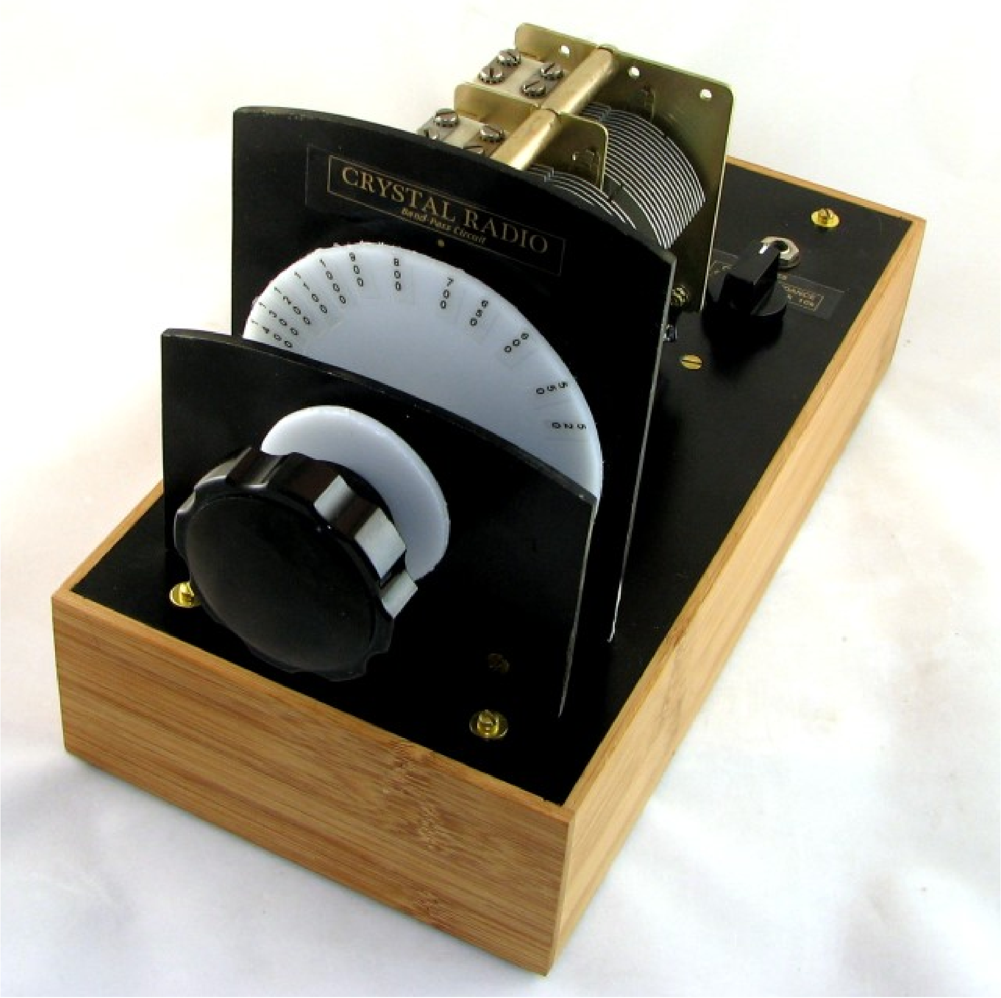
The contest gave me the needed nudge to really exercise the receiver and learn about it's strengths and weaknesses. I only tuned a lower CW portion of 40m (7.025 - 7.070 MHz) but there were hundreds of stations that could have been copied over the weekend period. Turns out there was a PA QSO party and a FISTS contest part of the weekend also. So there were weak and also extremely strong signals everywhere.

But I wasn't in the contest to score lots of points. I wanted to evaluate the receiver on weak & strong signals, so I restricted my station search to those calling CQ, especially the weak ones next to strong signals.

Click here for a link to Dave Schmarder's RadioBoard with a schematic and discussion of the radio.



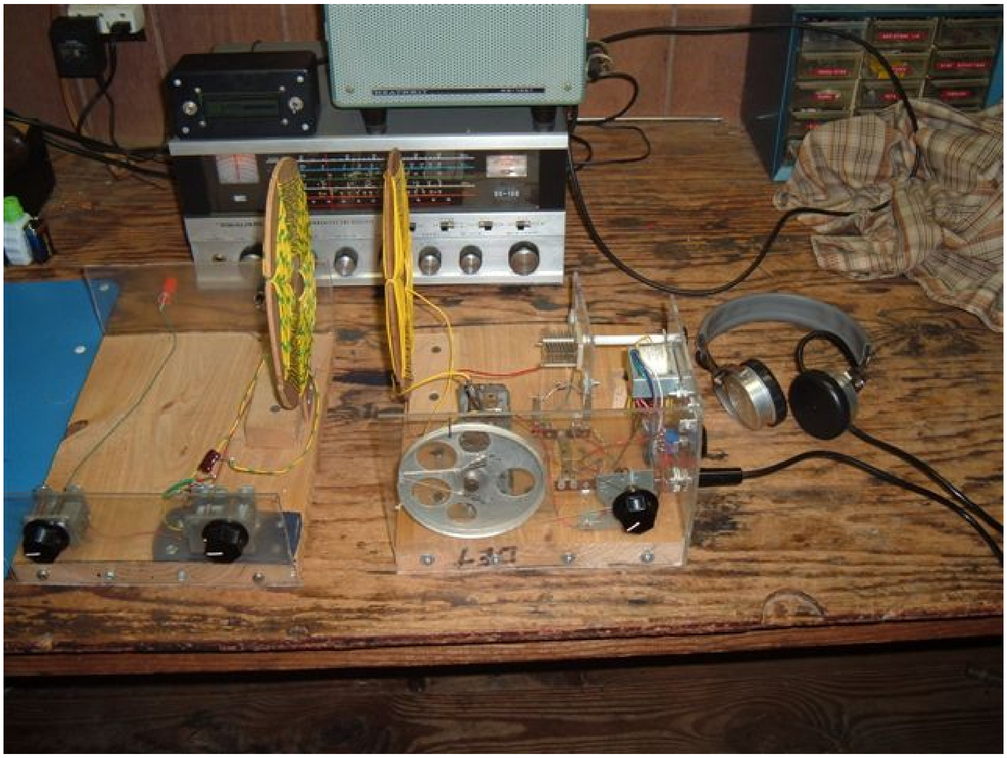
Dave Schmarder, BCB Class (crystal set)



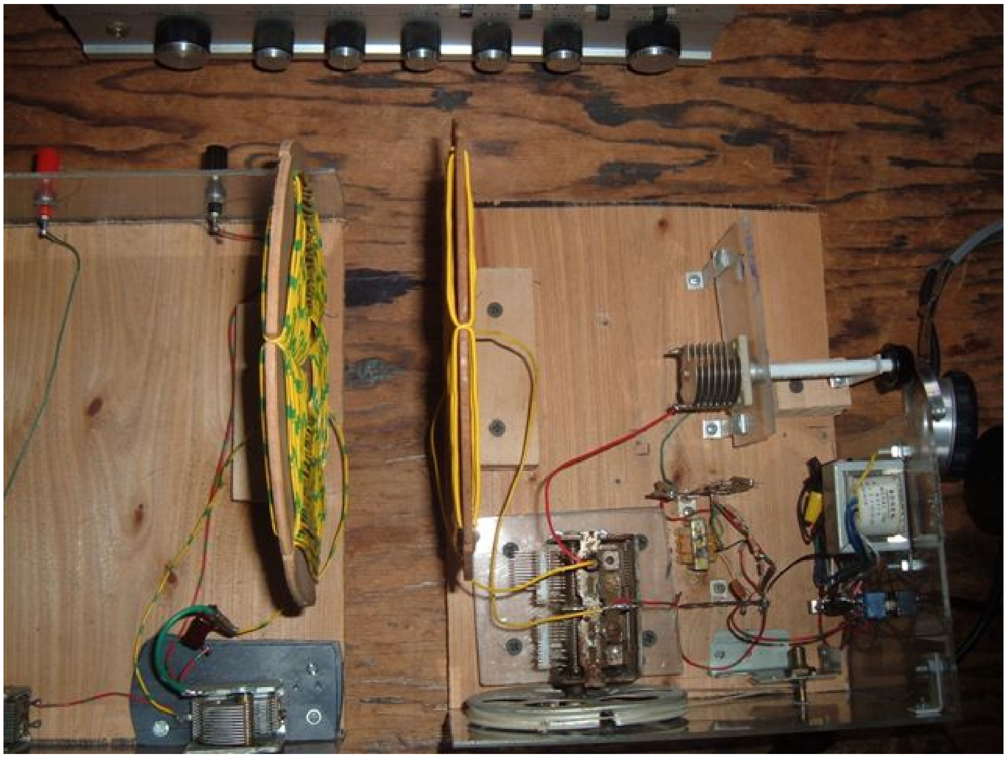
CRYSTAL RADIO
Band Pass Circuit

Here is the link to my contest entry. I just put up the Google map, so the page is now ready. I received 73 stations in the contest on my #76 crystal set. I had fun using my band pass radio. The outcome was better than I had expected.

Glen Yarbro, BCB Class (crystal set)



Dave's crystal radio #44
Headphones: Navy 4k
Diode: 1n34a
Antenna: 300 ft long wire



Gary Nichols, BCB Class (regen)

I was using a single J310 regen with a B+ of 4.5V. My tuning range was a bit below and above 680 and 1320. I forgot to measure it and I've already taken some of the set apart in preparation for mods.

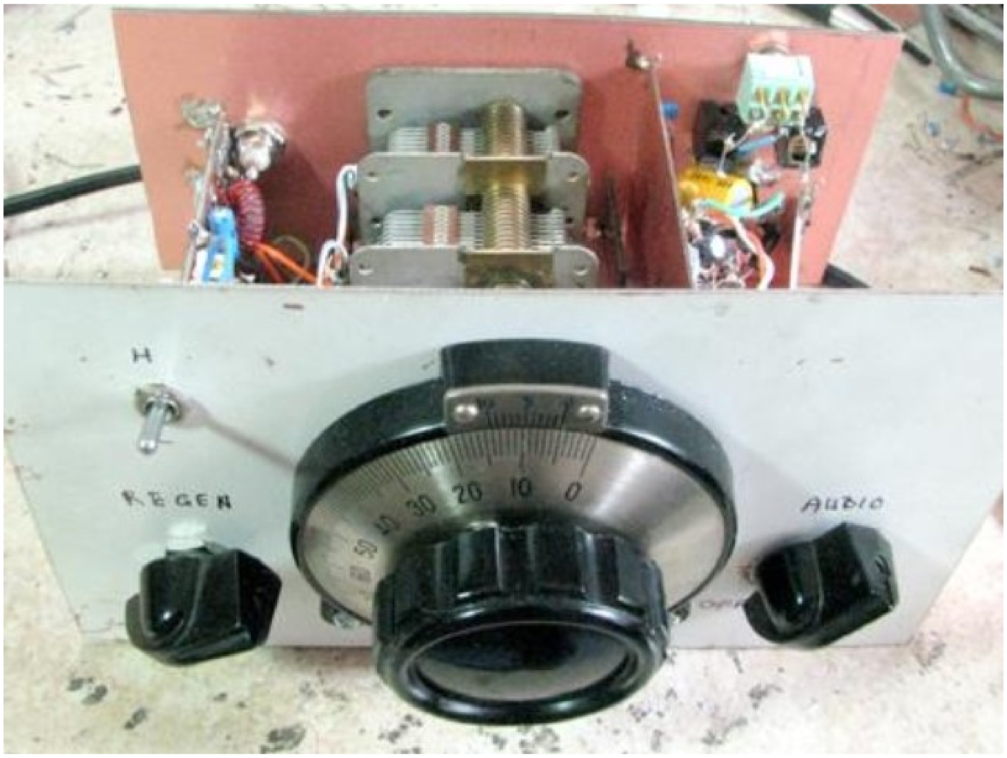
The restricted tuning range was due to the 30-145 pF ARC 5 variable that I like to use because of the really slow and precise worm drive. The set was a bit of a last minute effort, so I gave up on extending the range. I had plenty of stations to listen to anyway. My problem was that it seemed more difficult than usual to ID stations based on the info broadcast. There were a lot of games on over the weekend evenings and also the usual "sports talk" stations which are as bad as Radio Disney to identify, it seems.

I also forgot to listen for my area stations during the day! Ooops!

The antenna was about 50 ft of wire sloping to the ground from a 2nd floor window (10 ft of it inside). I sloped it south-westerly for possilbe best performance from my location here in the northeast near Syracuse, NY. My ground was the nearby 2 draw metal filing cabinet. One time I sat down to listen and noticed more than the usual hand capacity. I quick check and I realized I hadn't hooked up the filing cabinet!

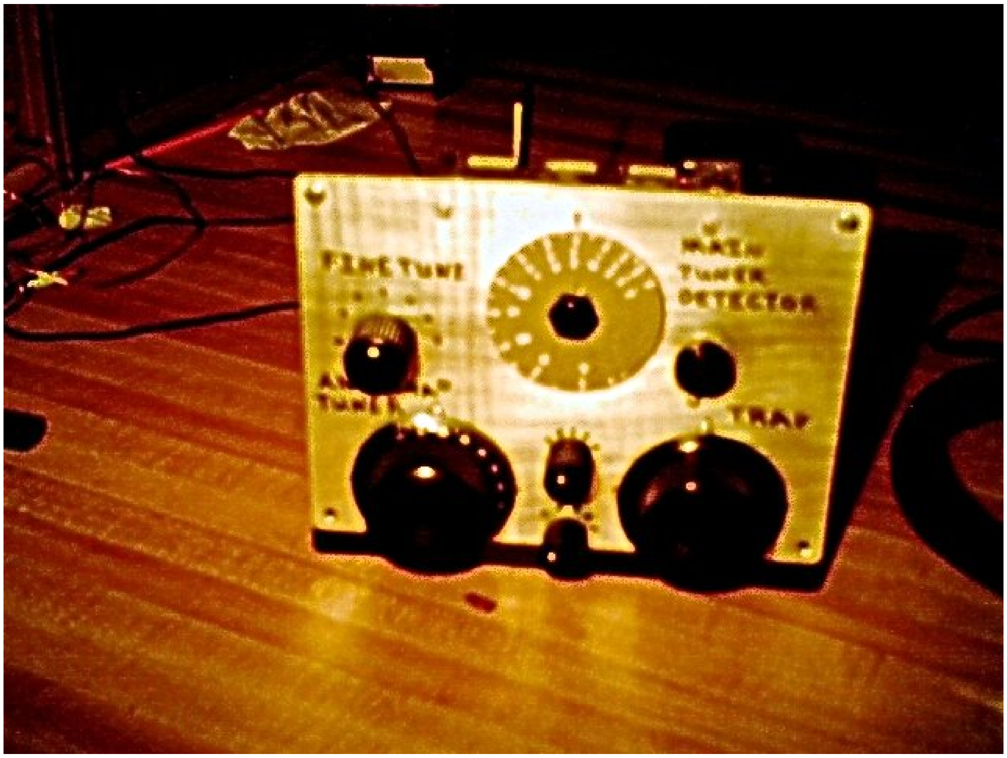
I used a "Bringhurst String" (5.6, 10, 22, 47 pF) of "clip selectible" fixed series caps between the antenna and top of the L/C to control signal strength and "pull" the tuning a bit up and down band.

James Kearman, BCB Class (regen)



My receiver was a homebrew solid-state regen, the one shown here. I used a homebrew air-core loop, 14-foot circumference.

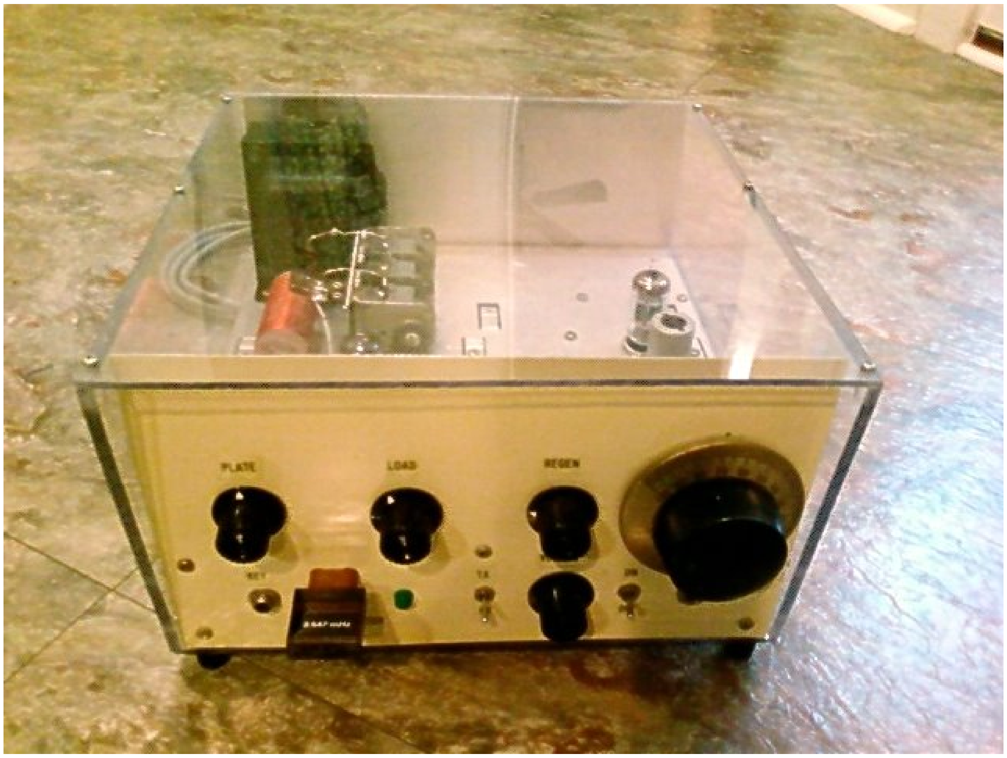
Sean Whiteacre, BCB Class (crystal)



FINE TUNE
MAIN TUNER DETECTOR
TRAP

The diode is a FT-205 Type. I used Dynalec Headphones and RCA Large Can Sound Power headphones.

Jack Bryant, Two-way Shortwave Class (regen)



I participated just a bit in the contest. I started Sunday night and made a two contacts and then one more early in the morning. The set you see was "rescued" from the Shelby, NC hamfest a few years ago. It was beautifully made with a plexi-glass case and painted front. It was sold as a non-working unit. I hated to see this fine construction job go to waste. The rig had a two tube crystal controlled transmitter and a two tube receiver, all in one package.

The receiver did work but covered about a 3 MHz tuning range. The vernier was a tiny one. I swapped it out for a NOS Velvet Vernier. The tuning range was narrowed down considerably, now covering roughly 3.500-3.508 MHz. I changed the top coupled detector antenna cap to 1.5 pf. The plate voltage on the regen detector was reduced from about 130 volts to 22 volts. The power cord was changed to a three prong cord.

The change in receiver performance is dramatic. The receiver is now very usable. I wanted some additional selectivity, so I put a .005 uF cap across the primary of the audio output transformer. I fed the audio output into my PC and used the Spectrogram program to check out the bandwidth. The audio peak is between 400 and 800 Hz, just right for my ear. The tube lineup is a 6CY5 detector and a 12AX7 two-stage audio amp.

The transmitter initially did have some output, but it was acting strangely. It turned out that the pi-network output of the transmitter had to be redesigned. It worked, but with an output at 40 meters instead of 80 meters! Some turns were removed from the coil and new fixed capacitors were installed. The output variable cap had to be changed as well. I had to fabricate a mounting plate so the existing front panel hole could be utilized.

Now the transmitter puts out 10 watts (plus or minus). It is sensitive to the type of crystal used. For the contest I used a small surplus 3.547 MHz crystal installed in an old FT-243 case. It worked great. The transmitter uses a 6C4 oscillator and a 5763 power amp.

This rig looks a Novice station project, perhaps from an old ARRL publication; however, I have not found a schematic for it yet. The station does work well. It drives either phones or a small external speaker.

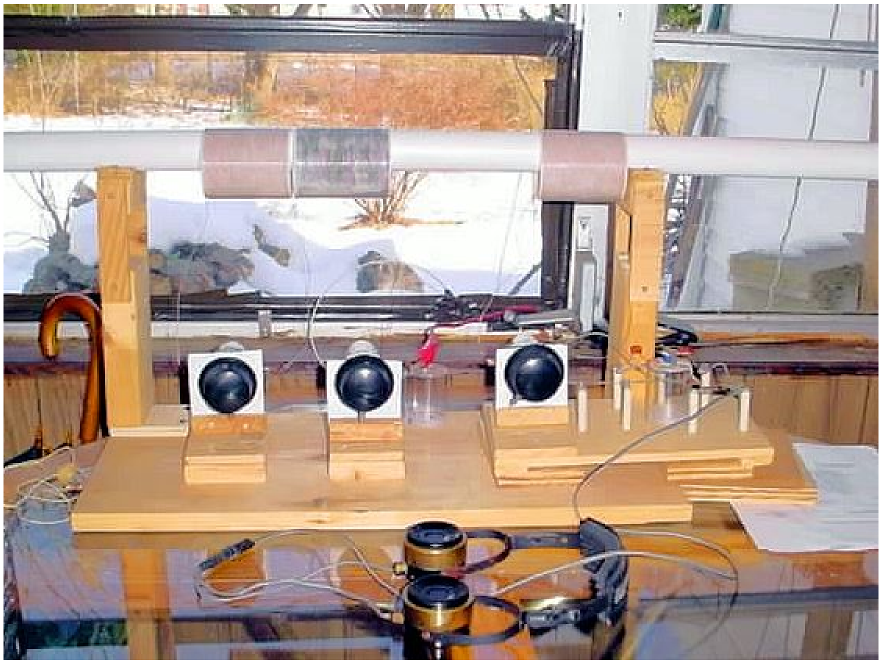
Crystal Radios Of The 2006 Contest Entrants

Page 3

Steve Hewlett



My 2006 contest set has three coils which slide on a polystyrene tube. From left to right they are wave trap, antenna coil, detector coil. All three coils are space wound (one wire width spacing between turns) copper wire; #24 ga. for wave trap and detector coils and # 23 ga. for the antenna coil.

A Single Jackson 365 pF VC is used on the wave trap coil and a single Jackson 410 pF VC is used on the detector coil. A dual Jackson 410 pF VC is used on the antenna coil in a Tuggle arrangement. The diode is a FO-215. A Calrad transformer and a "benny" (are included).

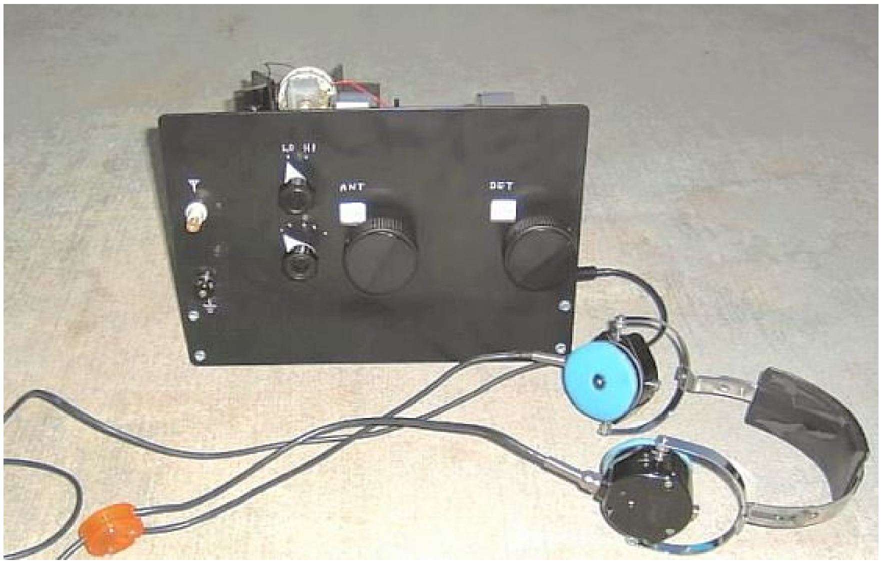
Jack Bryant



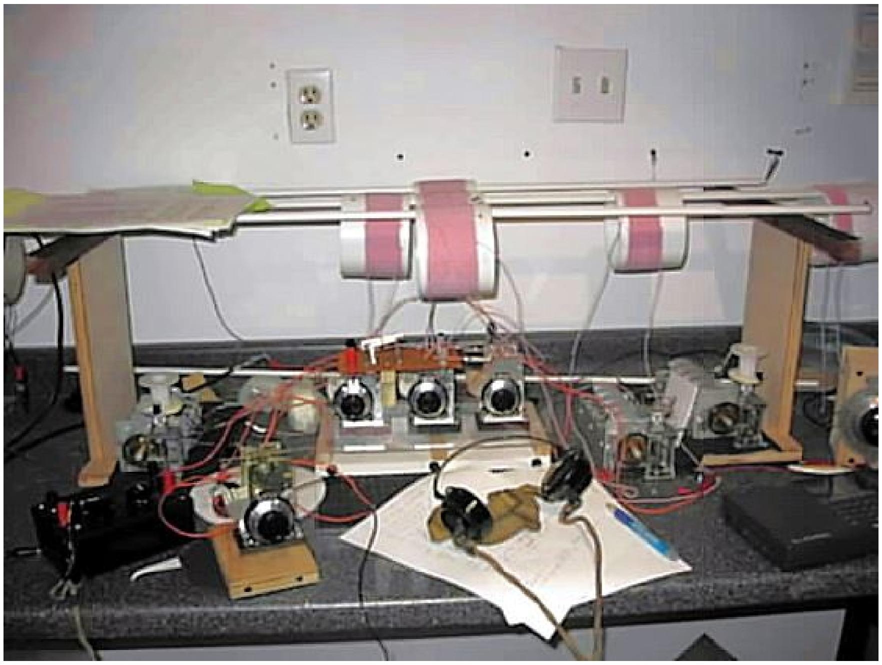
I used the same set in the BCB Open Class Category for 2004, 2005, and 2006. I tried the Hobbydyne in my toroid set, but my set worked better without it...too much signal loss. The selectivity of the set was already pretty good.

I did use an outboard cap this year in series with the set's built-in dual section cap. I liked it so much that I will probably modify my set and put the cap inside. Part of the reason for this is that my antennas are large with a lot of capacitance to ground. The standalone antenna cap adds a lot of flexibility.

Another mod to the set was a neon bulb connected from antenna to ground. This year we had some pretty good thunderstorms during the first part of the contest. When the bulb lit the room up, well, it was time to shut down! (I exaggerated just a little bit here.)

I did encounter a problem that I will mention, and perhaps you can avoid it. I wear glasses, and the constant pressure of my headphones against the ear piece of the glasses gave me a terrific headache. I apparently injured a nerve since it took me several weeks to recover. I am wondering if it is time for laser surgery so I can eliminate those glasses. You notice I didn't say stop using headphones…

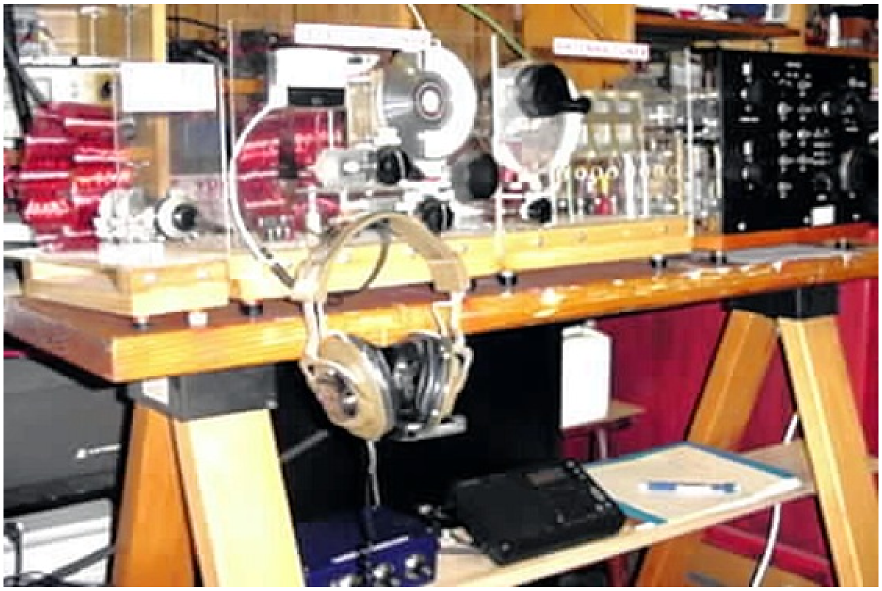
Gil Stacy



Set: Same set as last year. Headset: RCA Big Cans tuned> and recharged by Steve Bringhurst.

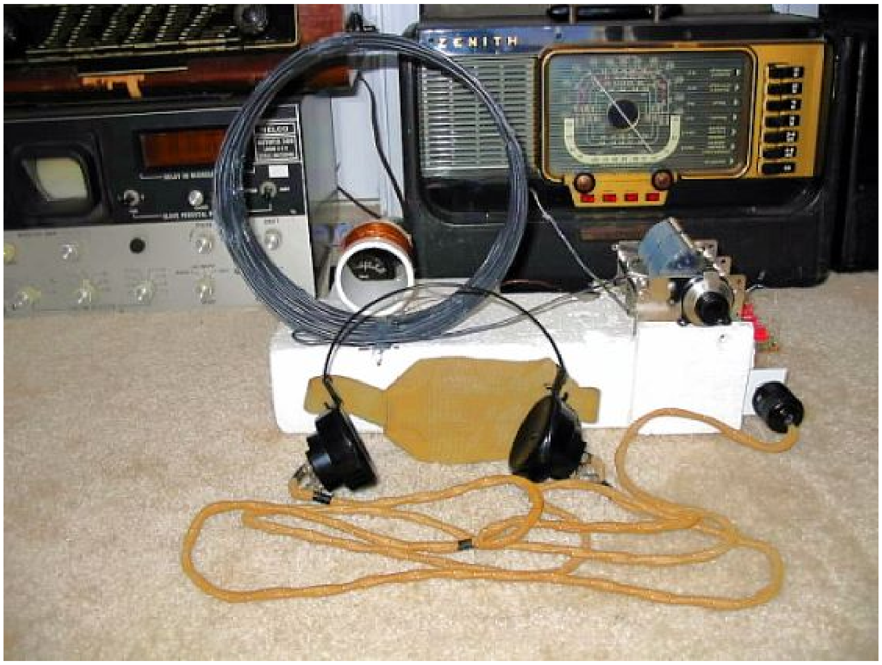
Antennas: 88’ top loaded vertical up 50’ and 180’ inverted “U” up 50’. Ground is the post 2004 DX DX contest ground described at the bottom of this page Set was the same as used in 2005. The antenna was a top loaded vertical cage antenna.

Lem Morrison



Set was the same as used in 2005. The antenna was a top loaded vertical cage antenna.

Alex Perez



Crystal Set DX 2006 Receiver

Despite the shortcomings that befell my design last year, the exact same setup is employed this year. The antenna spans a length of approximately eighty feet in a northeast to southwest orientation, rising to a height of forty five feet at the far end from the initial twelve feet. A convenient cold water pipe serves as a ground and is connected with a fifteen foot length of wire running horizontally. In order to minimize losses, an eight inch diameter twenty turn coil consisting of fourteen gauge wire is utilized and tuning is accomplished with a high quality vernier driven variable capacitor across the coil. A small ceramic trimmer loosely couples the antenna to the top of the tank circuit. Last year, the advantages of Schottky diodes were realized and a single BAT28 performs admirably in the design. A high impedance transformer matches the high impedance detector output to the low impedance DLR No. 5 headphones. These sound-powered headphones were most graciously provided as a prize by the contest committee two years ago and were instrumental in greatly boosting the DX capability of the receiver. A simple inductively coupled trap must be in place at all times. At night, it opens up a few hundred kilohertz around WXEM while during the day, it enables the reception of weaker stations across the band.

Band conditions seemed different this year but proved to be advantageous. After considerable experience gained during the preceding contest and an overall greater familiarity with band conditions, I promptly logged the majority of the typical nighttime band markers. The ensuing evenings resulted in only a few new nocturnal DX catches. Regrettably, I should have exploited the terrific grayline conditions to a greater extent this year. Nonetheless, many stations and points were gained due to a more casual approach to grayline DXing. Typically DX within fifty kilohertz of WXEM is impossible, even at night. Nonetheless, stations were logged on 1410, 1500, and even WXEM’s own frequency of 1460 when it decided to completely shut down for a short while. Following in the pattern set by my previous participation, I did surpass my score considerable while greatly enjoying the Contest.

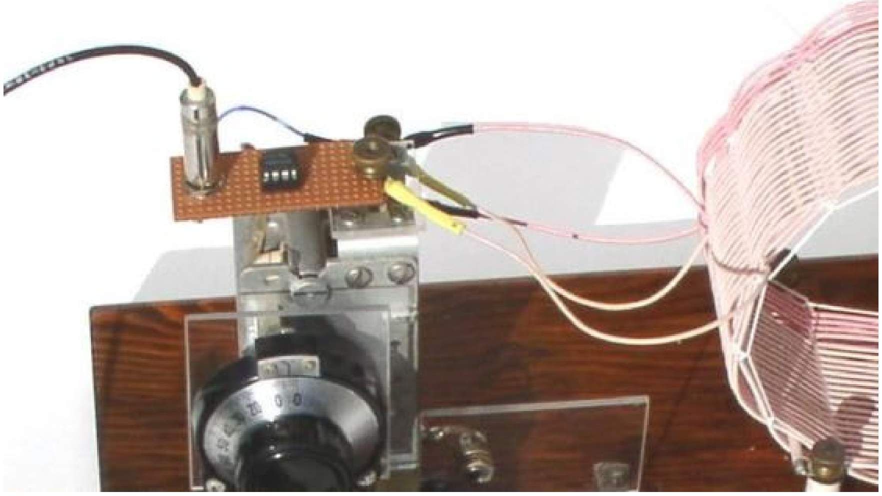
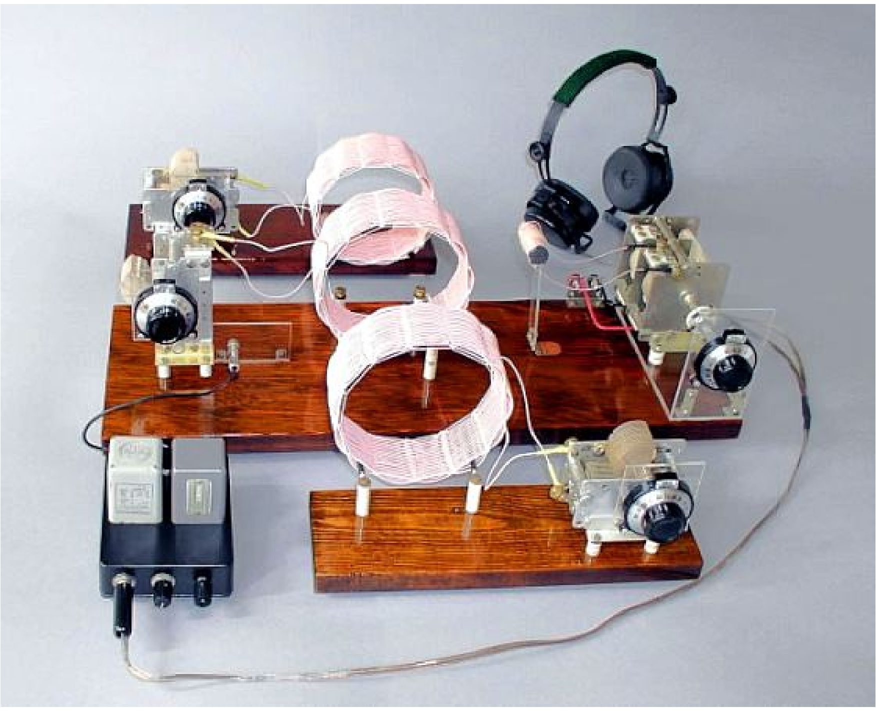
Crystal Radios Of The 2007 Contest Entrants

Page 1

Mike Tuggle



This detail shot shows the original Lyonodyne C2 and L2. The entire set can be seen below.



The MOSFET detector is mounted on its own circuit board along with its output jack. This board mounts to the set using the thumb nuts that attach L2 to C2. L3, a darker shade of pink, is mounted in back ('cold' end) of L2. The original diode output at bottom-center was not used.

To me, the most impressive feature of the ALD MOSFET detector was its superb selectivity. This makes sense, since the GATE presents essentially a zero load to the tuning tank, thus preserving its Q.

Volume, especially on weaker stations, was noticeably less than that delivered by the single diode detector. This may be partly due to the less-than-ideal matching between DRAIN-SOURCE and the audio matching and output circuits. Didn't have much time to play around with matching before the contest started.

Many thanks to my 'Benefactor' who provided the much-needed ALD110900A's during our recent national shortage.

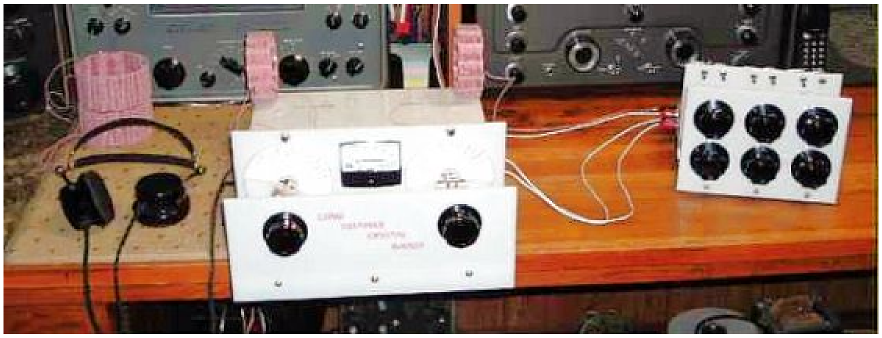
MODIFIED LYONODYNE CRYSTAL SET

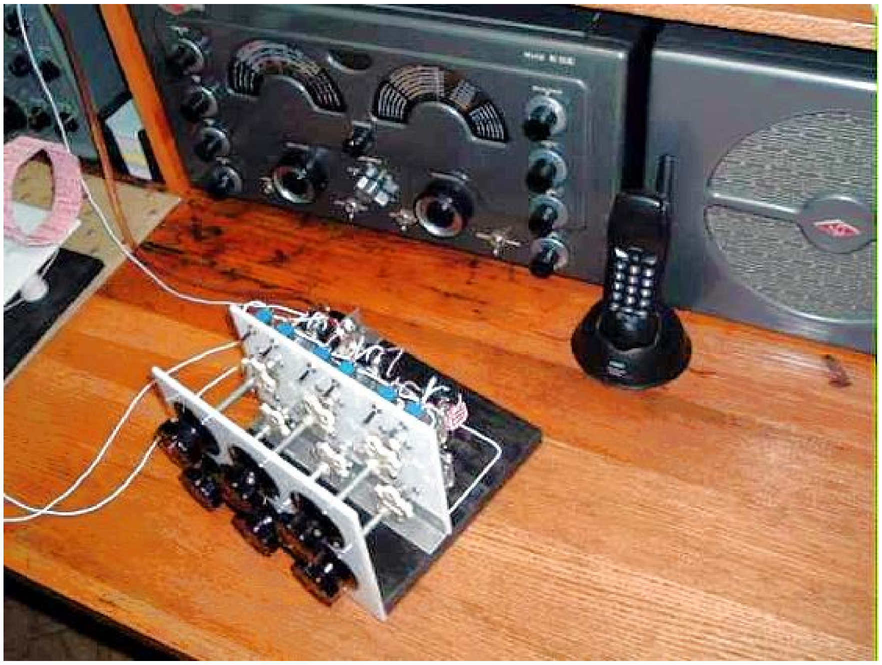
For my 2007 XSDX set I adapted one of the popular ALD110900A zero-voltage-threshold MOSFET detectors to the Lyonodyne. The highest voltage, at the top of the secondary tank, is applied to the MOSFET GATE. An added-on 8-turn coil L3, closely coupled to the 36-turn secondary coil, feeds the DRAIN-SOURCE and audio load.

Evan Haydon



Another fun Elmer Memorial Crystal Radio DX Contest is over. I used the same crystal radio that I used last year with only a couple of improvements. I bought some 420/46 litz wire for my coils. The Q of the coils used in the crystal radio is now 800 from 550 khz to 1200 khz. The Q then tapers down to 600 at 1700 khz. My six toroid traps are all wound with the same litz wire and have a Q of 400.

My antenna is the same as last year except that both ends are now up 40 feet. I am now using a good set of Big Cans for headphones with a bogen T725 transformer for matching to the radio.



I did my usual listening to the broadcast band almost every evening and some mornings from the middle of September up to contest time. I made a lot of notes. These paid off in time saved finding and identifying the largest number of stations possible during the contest. It is amazing how fast some stations appear and fade away at the gray line. One has to be on the right frequency at the right time to catch them.

The band conditions here were very good the first day of the contest. The second day was really pretty good too. After that, the conditions were generally poor with some spotty openings. Here are some of my statistics for the contest.

Day	Hours spent	Stations found
1-12	15.5	166
1-13	9	34
1-14	11	23
1-15	12	19
1-16	11	19
1-17	6	8
1-18	7	8
1-19	6	3
1-20	5	5
1-21	8.5	4
	91 hours	289 stations

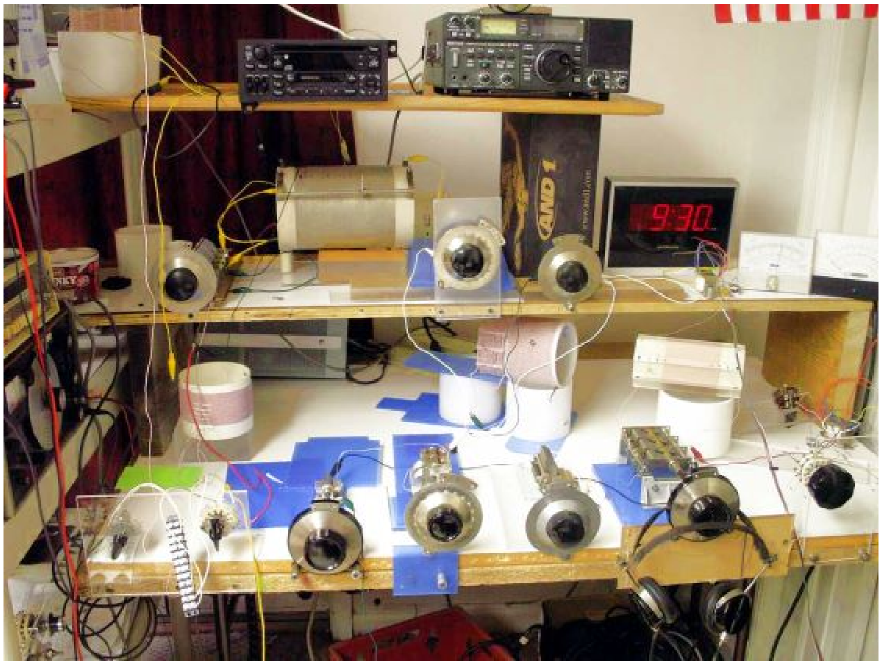
Some of the stations heard during the contest:

WWRV 530 khz South Caicos Islands 1987 miles
CMQ 670 khz Cuba 1483 miles
CM 530 khz Cuba 1481 miles
CKWX 1140 khz Vancouver, BC. Canada 1400 miles
KNBR 680 khz San Francisco, CA. 1379 miles
WBZ 1030 khz Boston, MA. 1333 miles

My personal choice for best catch during the contest:
KGBC 1540 khz Galveston, TX. 250 watts 804 miles
Good copy for an hour on the evening of Jan 19.

On an average winter day I can always hear about 55 stations. Most are within 175 miles. One everday station heard is 5 kw at 247 miles. My all time list of stations heard on my crystal radio that ID in English is now 412 stations. Let's do it again next year.

Bob Jewell



ANTENNAS:

1.Long Wire approx. 200 ft long, up 80 ft, lead-in approx. 100 ft, all one-piece litz to rig.

2.Four element 20M colinear antenna, fed with 300-ohm feeder, used as three antennas. Up 85 ft. 3.Misc. Spotter small antennas.

ANTENNA TUNER:

Seven inch diameter, 6.5 inches long, ceramic form, space wound, 90 turns, bare silver plated wire, selectable on each turn.

Capacitor: 4 section, 570 pf each, Variable, ceramic insulated silver plates. Wired series and parallel.

RIG:

1.Antenna coil: Large (?) litz on 4.5 inch diameter opaque plastic pipe form, close wound. Detector: 185/46 litz on 3.5 inch diameter ceramic form, space wound. Q ~ 650. (HP-4342A)

2.Grounds (2): house ground system, 200 gal LP tank underground, water filled. Connected with 50 ft of RG-8 coax, inner conductor and braid paralleled.

3.Diodes (22): different TYPES, on ceramic rotary switches, instantly selectable. Favorite soldered in.

4.Capacitors: ceramic insulated, silver-plated, approx. 550 pf.

5.AUDIO: Bogen T-725 plus 200K to 1000 ohm
45-703, miniature transformer.

6.HEADPHONES (3): USI, 1247-A, mike elements wired in series. (2) N.I.B. (Ebay, no name) soundpowered headphones, one set series, one set parallel wired.

7.All traps, (3), ceramic insulated caps and litz coils.

8.“Tuggle” type circuit.

9.“S” meter: Olson TE-380 meter, 0-8.7 ua,
Heath: 0-200 ua, series connected.

10.All internal RF wiring 185/46 litz.

11.ALL components mounted on Plexiglas sheets.

12.Many “Classic” vernier dials.

ACCESSORIES:

1.Icom R-70, spotter
2.Chrysler van auto radio, spotter
3.Icom PCR 100 with PCR 1000 software, spotter.
4.B&K Signal Generator, E200-D, frequency verification.
5.B&K, 1851, Frequency counter , frequency verification.
6.H.P., 4342A, Q meter. (max Q ~ 1000).
7.Heathkit, QM-1, Q meter. (max Q ~ 500).

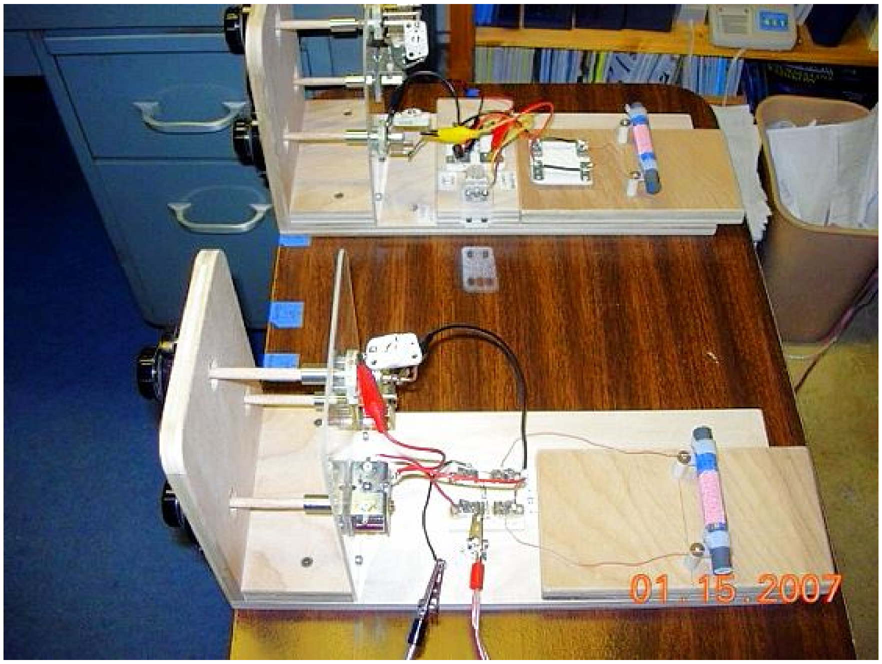
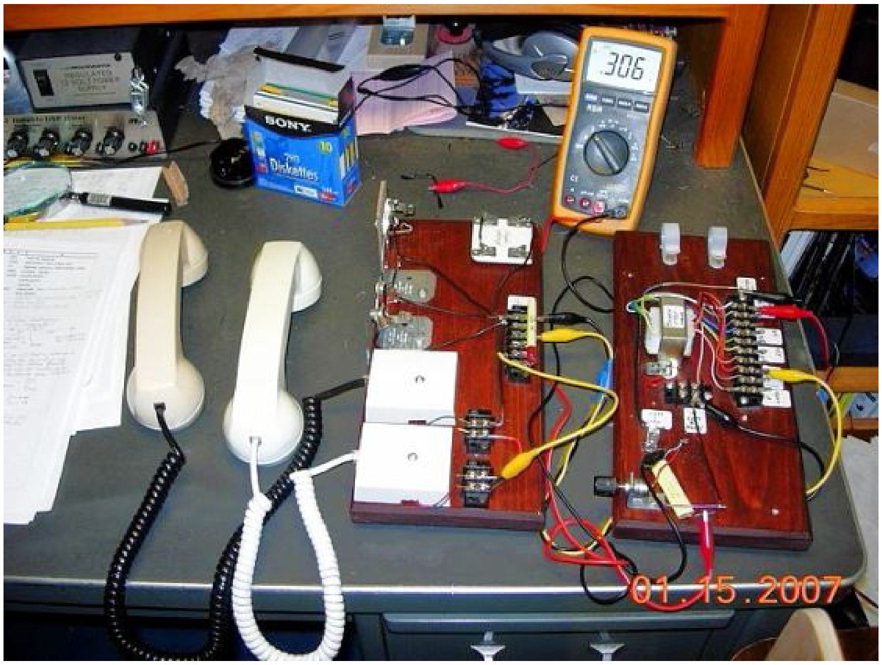
This circuit is a hybrid of Steve Bringhurst's select to match circuit and Dave Schmarder's toroid set #45. The design goal for this radio was high performance in a small package. The case is 9 inches x 6 inches deep x 1 3/4 inches tall. The toroids are FT 114A-61 amidon cores, L1 tapped at 12 turns. The toroid coupling coils are wound on a small tube with an ID slightly larger than 3/8 inch. The first coil is close wound, 15 turns. The second coil is triple spaced, seventeen turns. Both coils 24 awg and are approximately 29 uH with coupling accomplished by moving a 3/8" x 4" ferrite rod in and out of the coupling coil's tube. The detector used was a pair of HP 5082-2835 schottky diodes. The phones used was a pair of Philmore xtal earplugs in parallel thru a radio shack mono Y adaptor. The antenna used is a half sized g5rv ham antenna approximately 25 ft up, center conductor & braid of the coax connected together. Ground system is 3 four foot copper clad steel rods 8 ft apart connected with #14 awg solid bare copper wire.

The detector cap sometimes has a very slight but noticeable bit of hand capacitance at times, it seems to depend on the weather. All in all a good performing radio.

Dan McGillis





For the 2007 Crystal Set DX Contest, I used an all ferrite-rod double tuned set-up: Detector - ATU - Wave Trap.

The inductors are Amidon Ferrite 61 0.5”x4” ferrite rods with 165/46 Litz coils wound directly onto the rods. All capacitors have ceramic insulators. Detector tuning is split into 3 ranges to cover the broadcast band. Each range has it’s own capacitor, trimmer and 8:1 vernier dial. The “Tuggle tuned” ATU is split into two ranges - each with its own capacitors and 8:1 dials. The inductively coupled wave trap has one range and a 48:1 vernier. A FO-215 diode is Hobbydyne coupled to the top of the detector coil - no taps. Diode output goes to a Bogen T-725 transformer then to two USI UA-1614 sound powered elements in series - or - standard telephone handsets in series.

The antenna is an end-fed 200’ inverted Vee with it’s apex at about 40’; ground is a 4’ pipe driven into the ground.

Dial number-to-frequency calibration curves for the detector and ATU were converted to vernier dial numbers for every 10 khz of the broadcast band. A station heard on a digital read-out Yaesu FT-757GX spotting radio could be quickly converted to crystal-set dial numbers - and vice-versa.

I think the bandspreading and calibration expansion are the best features of this set-up.

Dave Schmarder

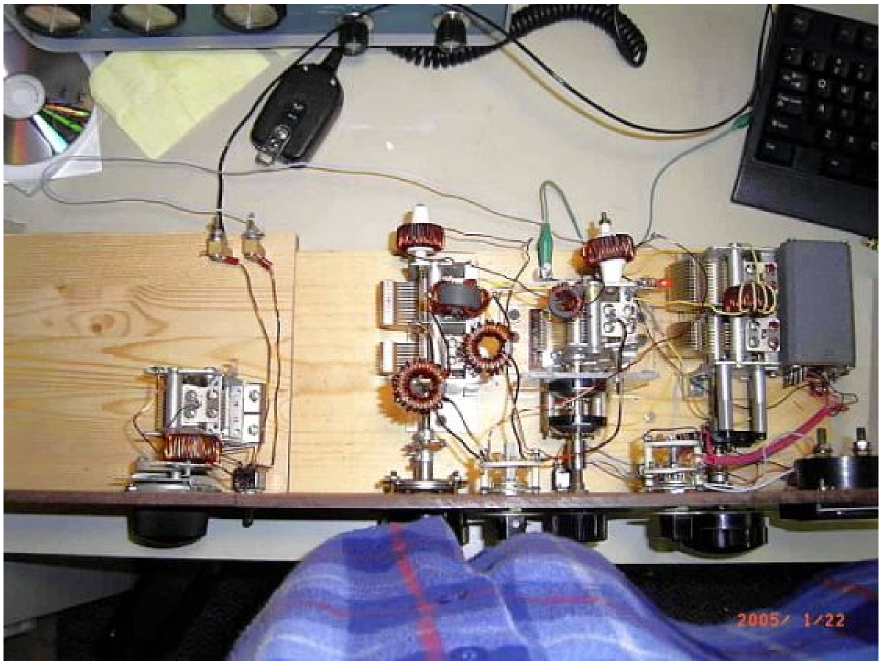
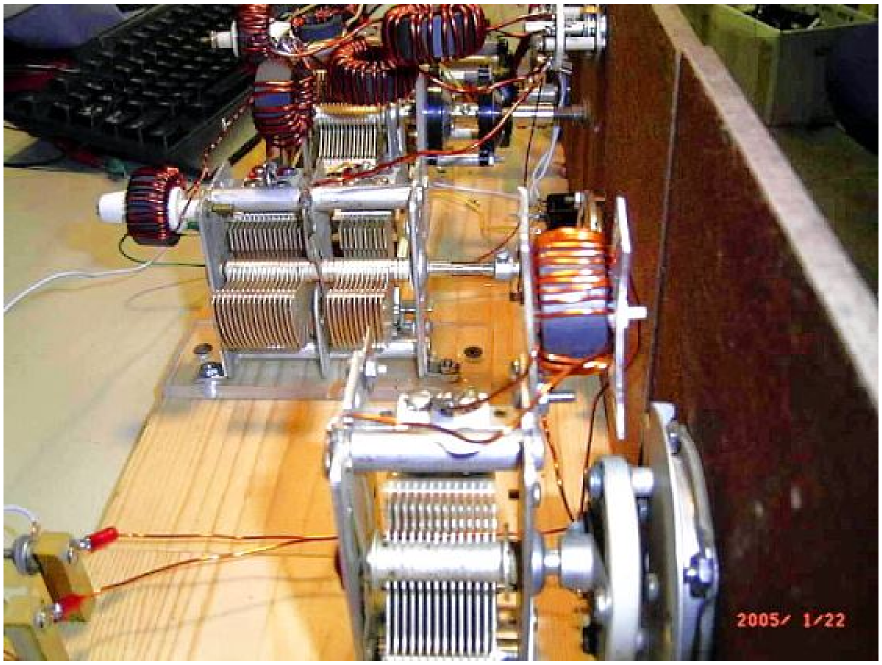
The "Litz Blitz" January, 2004

Here is a picture of Dan's set, the "Litz Blitz". This set is in the XSS Newsletter as an article in the March, 2004 issue.

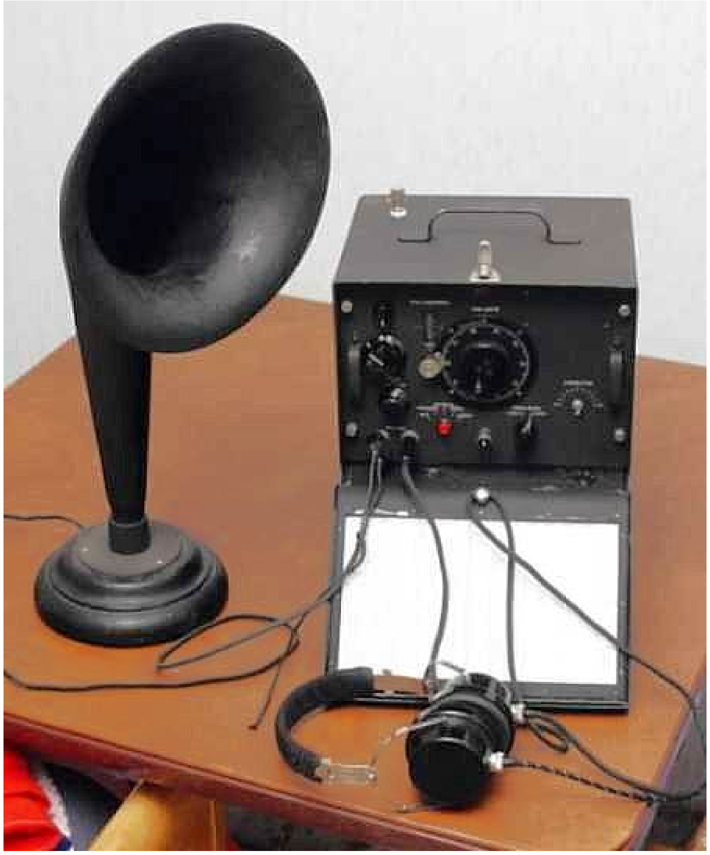
Brian Wingard



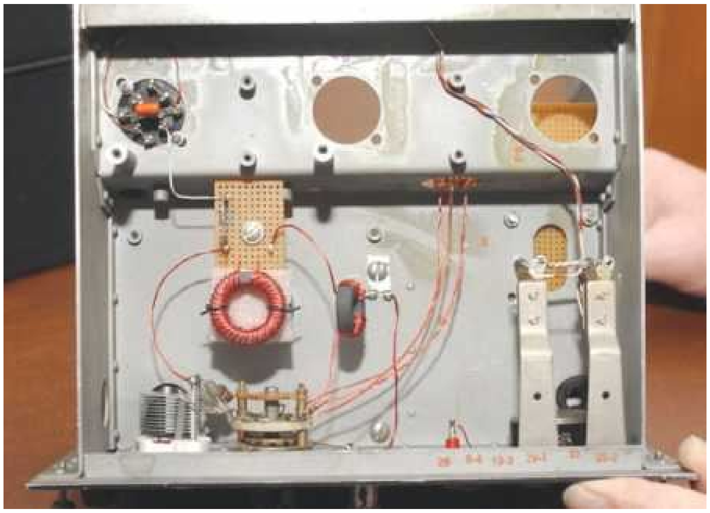
Notice the FT114-61 cores and large diameter wire. Brian uses separate cores for Lo Band/Hi band.



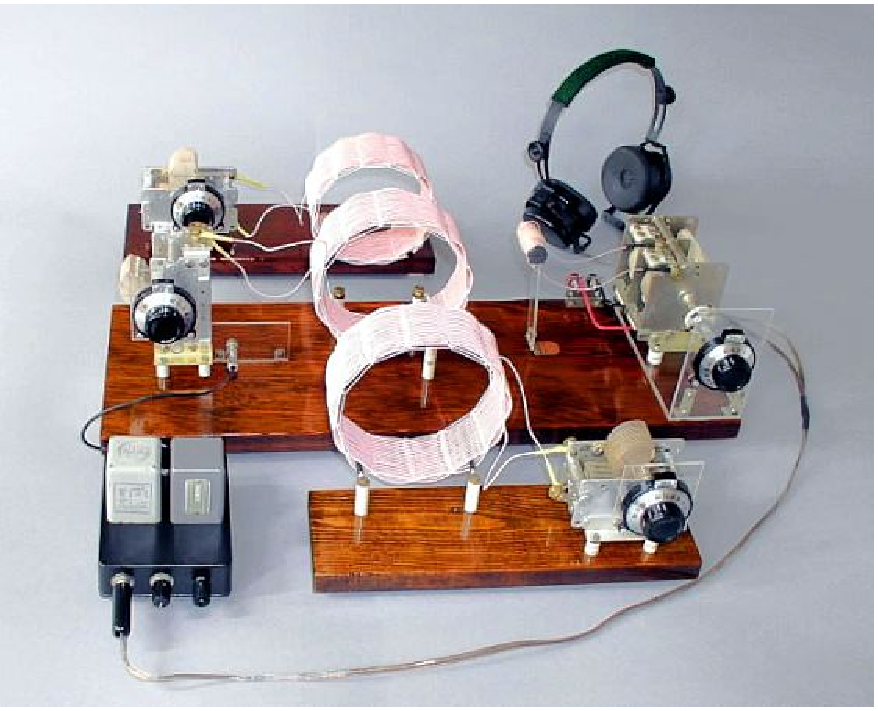
Steve Bringhurst



Steve uses a BC-221 as the basis for his BCB set. The BC-221 is a frequency meter, WWII vintage.

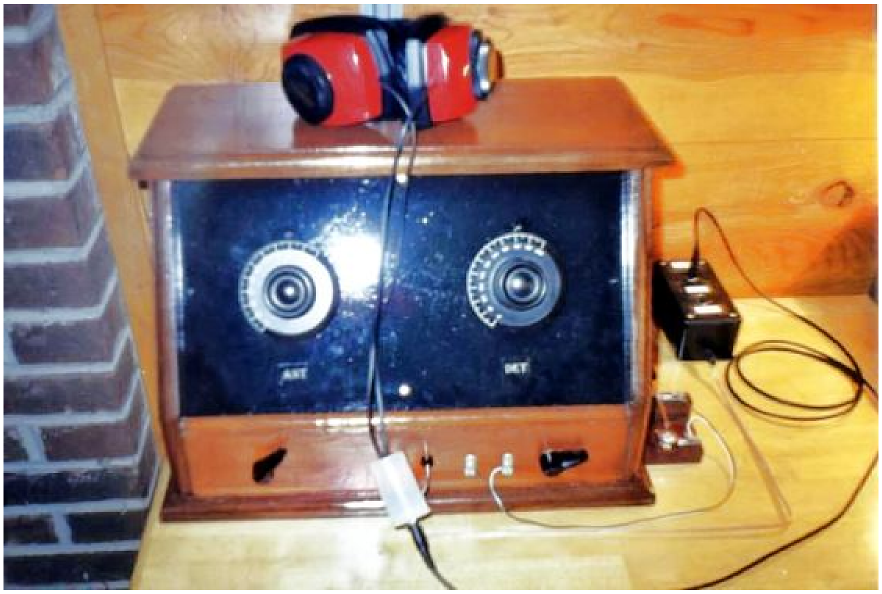


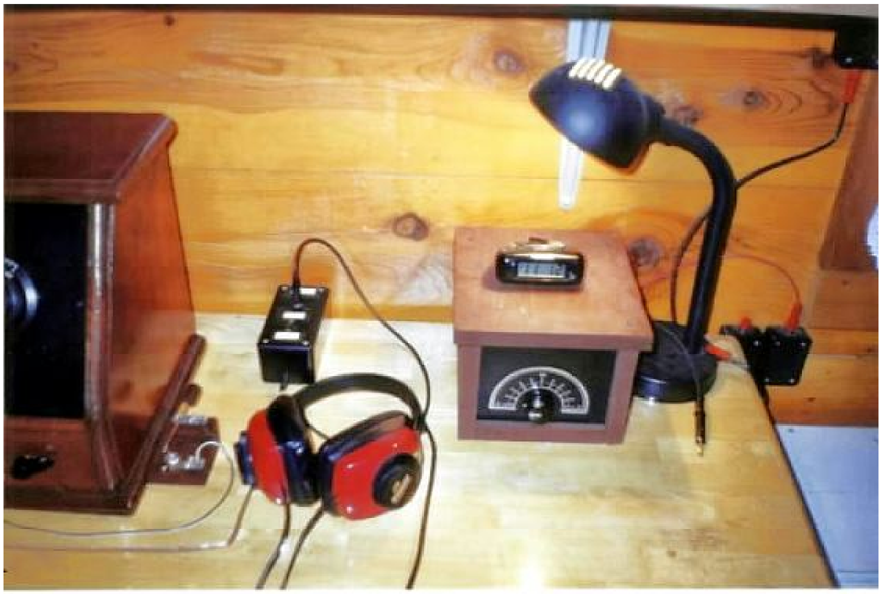
Mike Tuggle



Mike Tuggle's record smashing DX set.

Mike Branson





The matching unit.

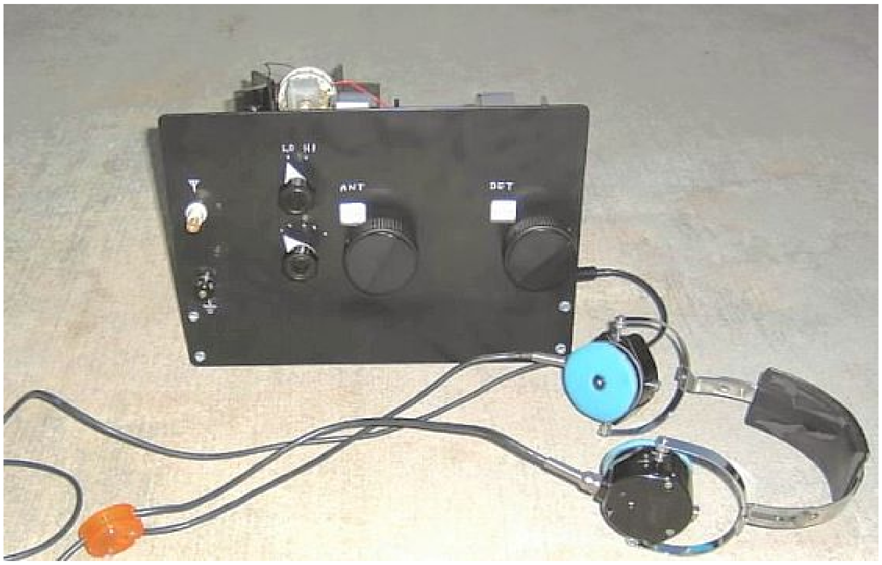
Jack Bryant



LO HI
ANT
DET

I started putting the set together on January 5, 2004...way late! I used a black plastic clipboard for the front and a clear orange plastic one for the chassis plate. 1"x3" small boards are used to hold up the chassis plate. I installed the coil supports during the contest and the phone jack afterward.

This set is a modified bandpass unit, but uses two separate coil assemblies. Each assembly consists of toroids wound on FT114-61A cores for the antenna and detector coils. Each assembly has it own coupling coil, connecting the antenna and detector circuits.

Here are the specs:

Lo Band
Antenna: FT114A-61, 33T #18

Couping Coil:FT-82-61, 10T ant side, 5T detector side, tapped every turn (det side only) Detector: FT114A-61, 40T #18

High Band

Antenna: FT114A-61, 22T #14 Couping Coil:FT-82-61, 10T ant side, 5T detector side, tapped every turn (det side only) Detector: FT114A-61, 20T #14

The audio transformer is one of the Fair Radio 100k:100 ohm units. The headphones are Dynalec mic elements. I started with one of the ITT diodes, then settled on one with a blue stripe (characteristics unknown).

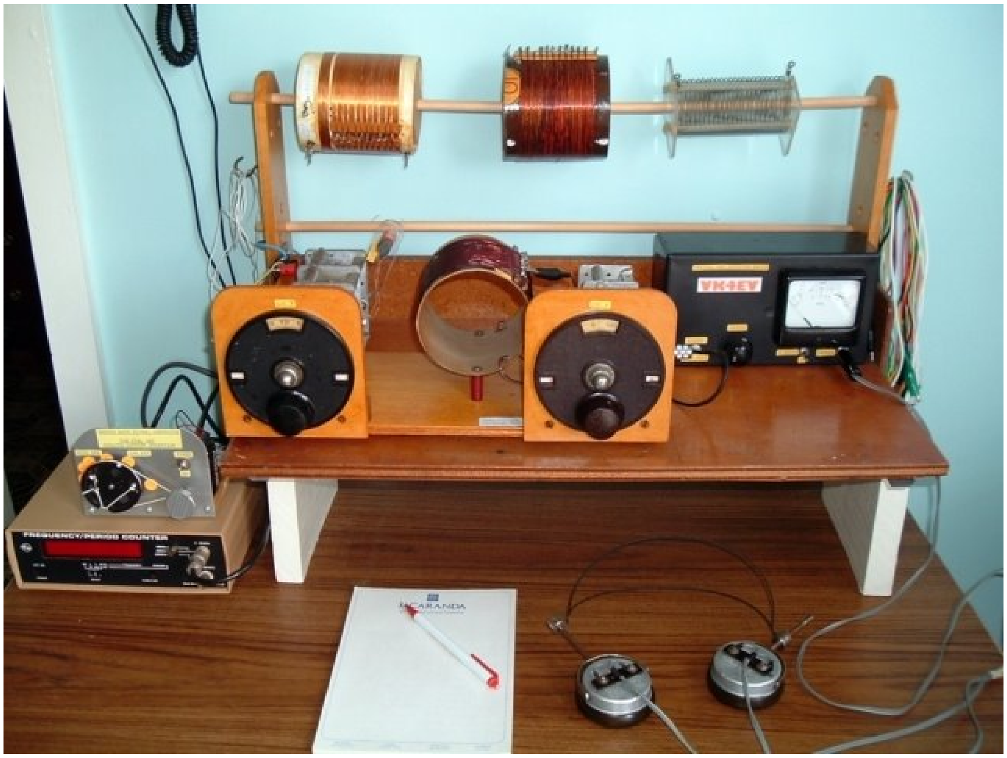
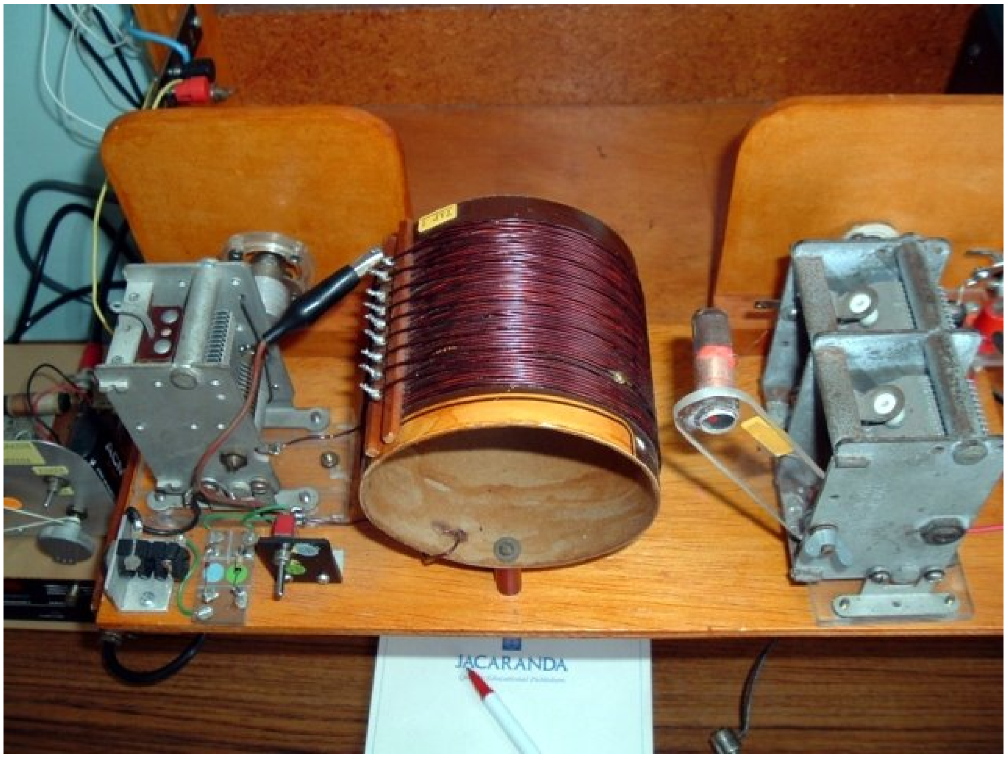
Crystal Radios Of The 2009 Contest Entrants

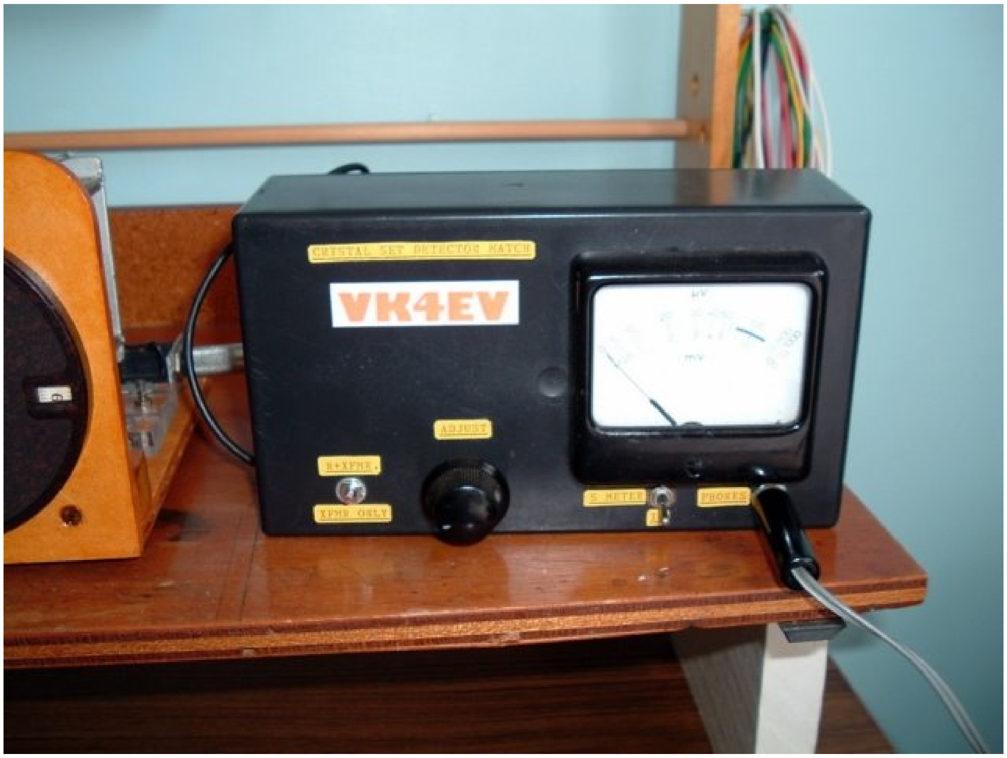
Page 2

Ron Everingham, Open Class Entry



VK4EV
FREQUENCY/PERIOD COUNTER
JACARANDA



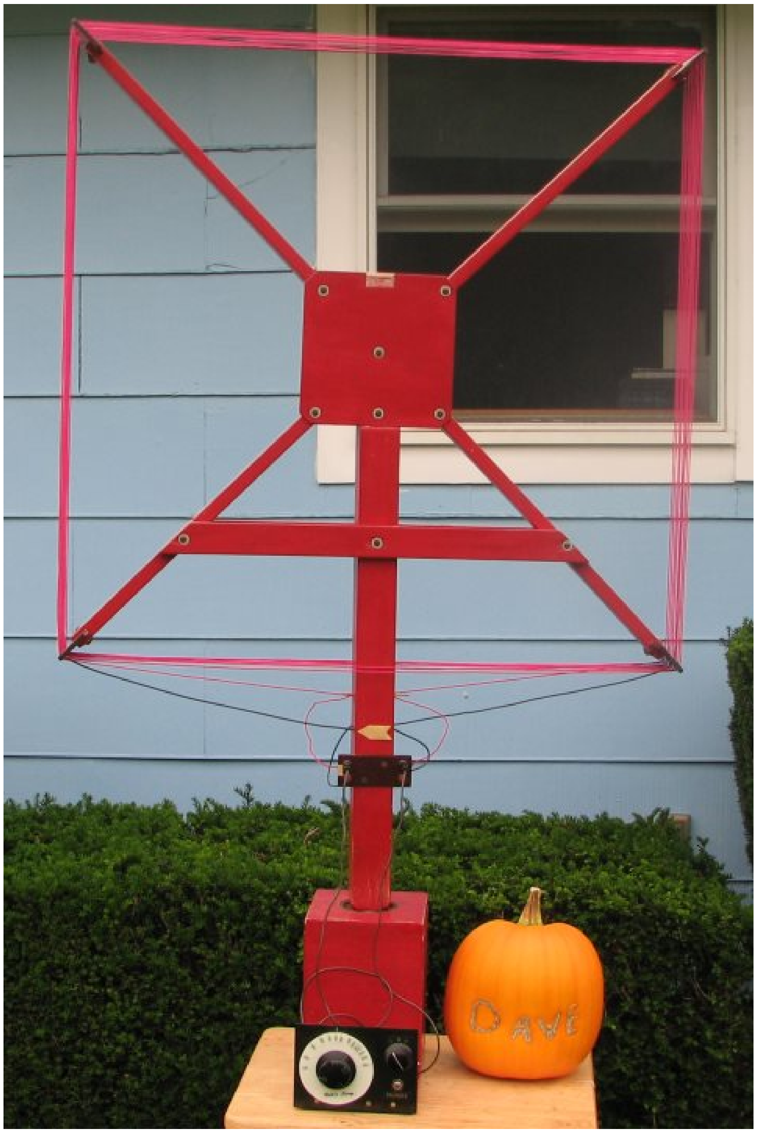


This double tuned radio is really my first attempt for DX listening by virtue of using two vernier dials, variable coupling and audio matching.

L1 is wound on a piece of ferrite rod connected to a swinging arm to obtain variable coupling for L2. The S meter is a surplus 30uA movement which gives a good indication for setting the tuning capacitors to a particular frequency when a signal generator is loosely coupled to the aerial.

The aerial used is about 20 feet high and 80 feet long bent to fit into my small lot.

Dave Schmarder, Loop Class Entry



To see Dave's log and contest set description click here. This will take you to his fine website. Here is his loop antenna description.

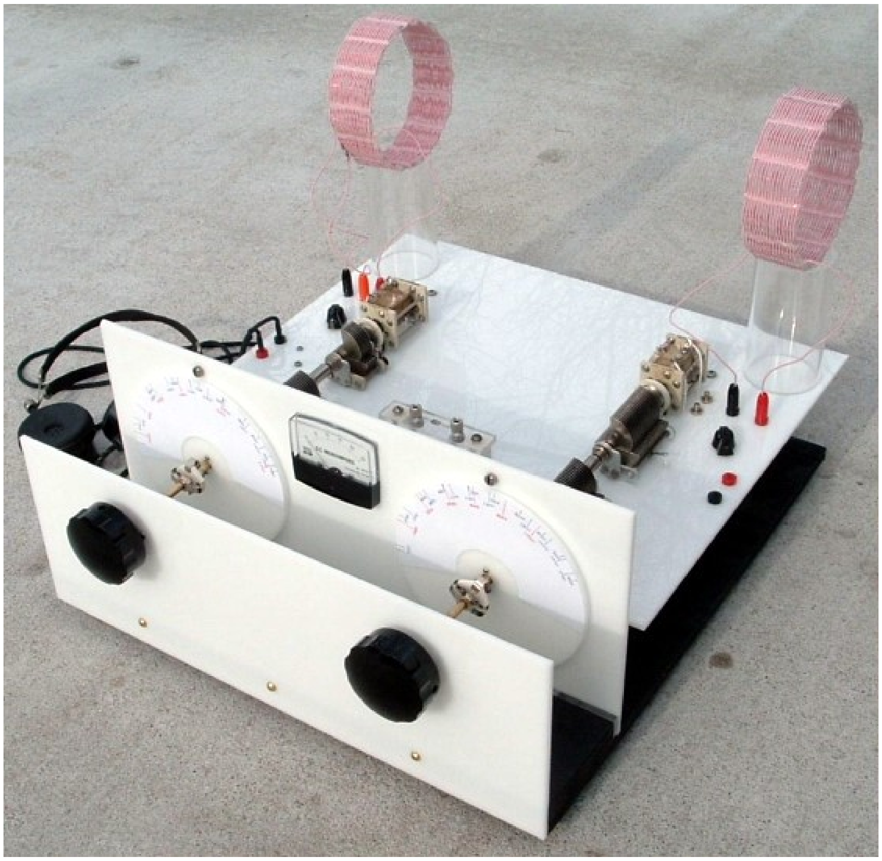
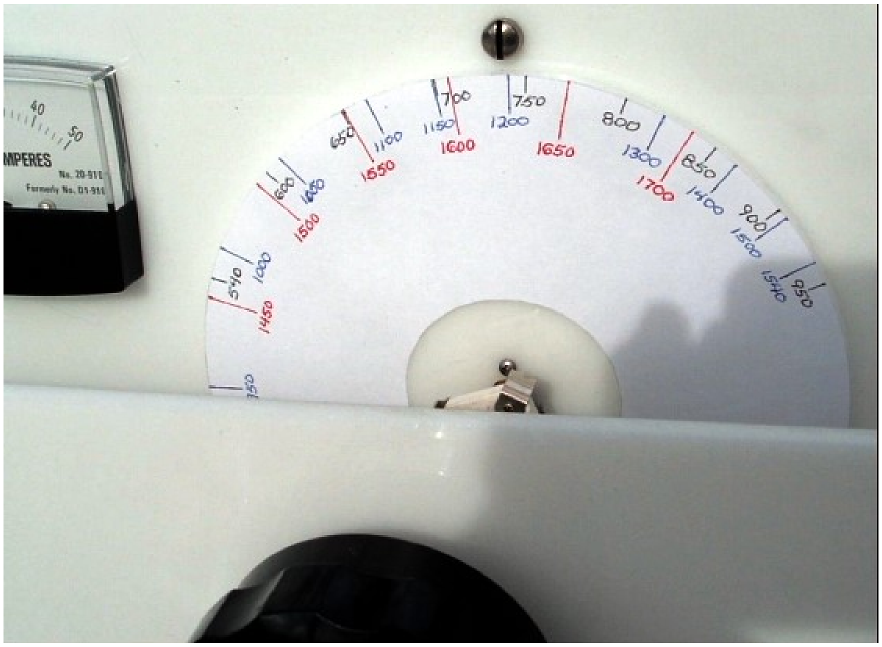
Jack used the venerable Miller 565 with an external audio matching unit. Notice the very rare 10 ua meter in his audio unit!

Evan Haydon, Open Class Entry





I spent a lot of time preparing for the 2009 contest. I spent many hours most evenings for the last three months listening to the broadcast band. From both notes made then and from memory, I am very familiar with what stations appear at what time of the day at this location. I watch band conditions carefully and fairly accurately know which stations it is even possible to hear at any time on any frequency.

My crystal radio will at night hear any signal that my spotter radio will hear except for weak signals 10kc either side of my 3 local stations. My crystal radio will hear 95% of the daytime signals that my spotter radio will hear. On a good cold winter day, I have received 57 stations. My radio, traps, and antenna system are exactly the same as used in the 2008 contest. I could not find any way to improve the system.

This year's contest had unusual conditions here. The first day had very good receiving conditions. The second day had good conditions. The band then stagnated. It did not change for the rest if the contest. The stagnant condition was not what I would call a normal winter condition either. There was no flux or change (due to weather conditions) to cause stations to appear and disappear. For day after day it was the same old stations all up and down the band.

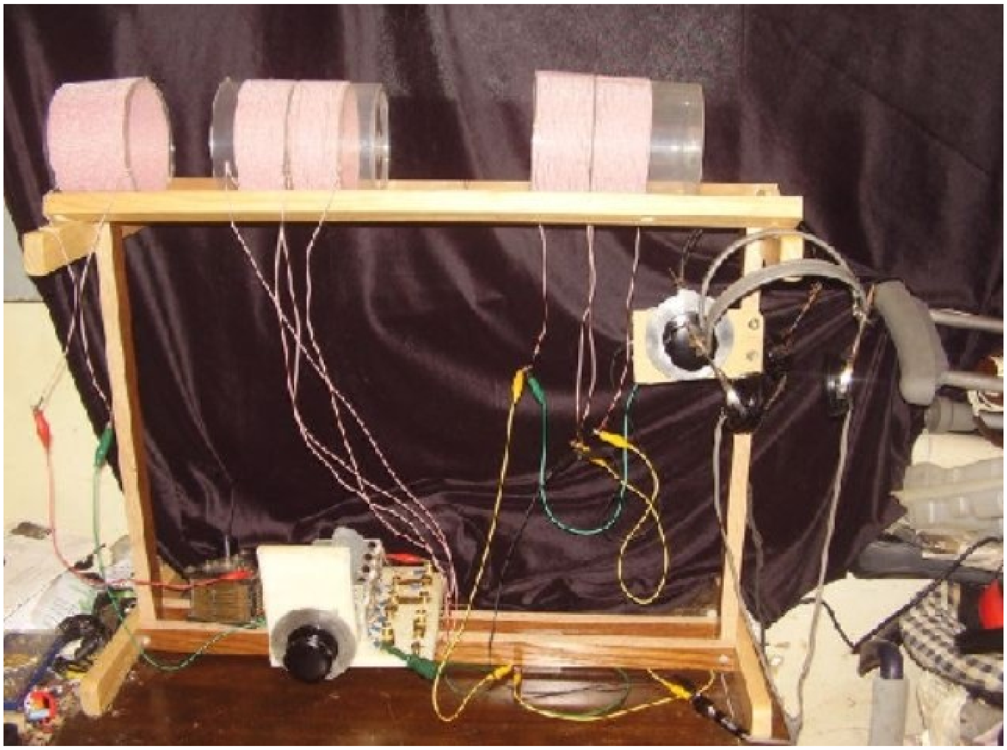
The contest was fun to work as always. My list of all time stations identified on the broadcast band now numbers 505 stations. I identified 66 stations this year that I did not hear in the 2008 contest. That means that I identified 36 stations in the 2008 contest that I did not hear this year. In the 2009 contest, I logged 4 stations from New York state, 1 from Boston, 3 from California, 2 from Philadelphia, and 25 stations from Canada. I identified stations from 31 different states, Canada, Mexico, and Cuba. IBOC probably cost me 3 or 4 stations to not be logged this year

Below is a summary of my activities during the 2009 crystal radio contest.

```
        Stations
Day Logged  Time spent
1-16   197   15 Hr  35 Min
1-17   32    12 Hr  20 Min
1-18   27    11 Hr  20 Min
1-19   21    11 Hr  10 Min
1-20   11     8 Hr   0 Min
1-21    9     7 Hr  20 Min
1-22    8     6 Hr  50 Min
1-23    8     8 Hr  15 Min
1-24    7     7 Hr  35 Min
1-25    8    10 Hr  20 Min

Total time spent - 98 hours 45 minutes
Total stations heard - 328
Total stations identified - 312
Total points - 583,312
```

Michael Bartolone, Open Class Entry



My current contest rig has contra wound solenoid coil 5.25 in diameter, each section 29 turns of "indoor antenna wire", 2.15in length per section, single gang 400pf air variable cap, unknown diode scavenged from a clock radio picked up at Goodwill (the diode has two red bands on one end and no other markings), Clevite brush phones.

Coils suspended in a slide cradle 20 inches above the desk. The tank is loose coupled to an ATU with contra wound solenoid coil 5.25in diameter, each section 26 turns switchable so I can use either single section, or both in series, or in parallel, with a 5 gang 380pf per gang cap switchable to put various gangs in series or parallel with the various coil configs.

One tunable trap with a single 5.25 in diameter coil, 43 turns, 3 in long with 440pf cap for tuning.

Note the 'indoor antenna wire" is like very cheap litz…35 strands individually insulated but only twisted, not braided like true litz. However, the price was too good to pass up ($0.02 per foot when I bought it).

My antenna is a 75+ foot long wire (16ga speaker wire) average about 12 feet above ground, run from the eaves at one corner of the house to a tower about 35 feet from the house and then back to the other corner. The ground is a single copper clad rod about 3 feet long about 2 feet into

This year’s crystal radio contest was fun, even though it was long. The broadcast band conditions in Lincoln were what I would call normal or generally good. I used the same crystal radio and antenna setup that I used in the 2009 contest.

23 radio stations that I identified in the 2009 contest were not heard in the 2010 contest. I identified 24 new stations in the 2010 contest to add to my all time heard list. That list now stands at 536 stations identified. For that number, I only count US and Canadian stations.

In the 2010 contest I heard stations in 33 states from California to New York. I identified 30 Canadian stations, 7 Cuban stations, and 2 Mexican stations. The most stations identified on one frequency was 9 stations on 1190 kHz.

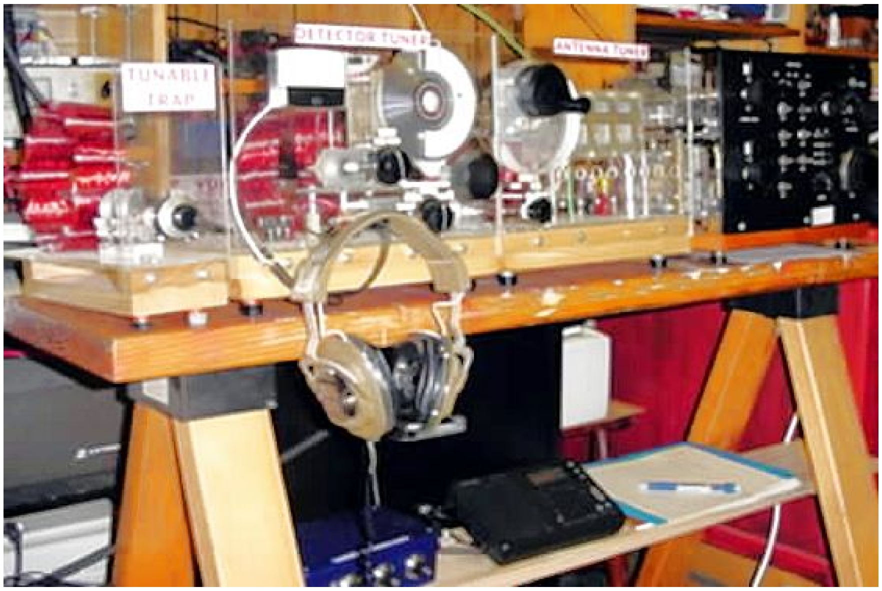
Lem Morrison



N4AHJ 2005 CONTEST CRYSTAL RADIO and OTHER INFO

The picture shown is the set in the 2004 Contest configuration.

TRAPS:
(1) Tunable (1) - 2-section variable, sections in parallel, 240pF total; Rook coil with 18 gauge wire, 5.25 inches effective diameter, 47 turns; loose-coupled to the Detector coil.

(2) Tunable (2) (located in AMU) - both use 14 gauge enamel wire on FT-114A-61 cores and dual-section variables with both sections in parallel.

(3) Fixed (9) (located in AMU) - 14 gauge to 22 gauge enamel wire on FT-114A-61 cores, silver mica fixed capacitors, and plated ceramic trimmers (one trap for each of the local “blow torches”). Each link-coupled to the antenna feed to the set.

ANTENNA MATCHING UNIT (AMU):
One 4-section variable capacitor, four fixed capacitors (500pF, 1000pF, 2200pF, and 5000pF), and two coils (42 turns 14 gauge enamel on a FT-240-61 and 26 turns 16 gauge enamel on a FT-114A-61). All components switched to provide four matching arrangements: series LC, parallel LC, inductance only, and capacitance only. Both inductors are tapped to provide 23 L settings. An antenna switch is provided for switching between up to five antennas.

BANDPASS TUNER:
Capacitor - 520pF variable, 2 sections used in Tuggle arrangement; vernier is a surplus right-angle unit with a 25:1 ratio.

Coil - Two Rook coils with 14 gauge enamel wire, 6.25 inches effective diameter, 15 turns each, 30 turns total; bandswitch provides either series or parallel coupling for Low band and High band tuning based on Ben Tongue’s approach; loose-coupled to the Detector coil.

DETECTOR TUNER:
Capacitor - 420pF variable with home-made vernier with a 32:1 ratio (vernier constructed from gears salvaged from a VCR and a TV tuner).

Coil - Two Rook coils with 14 gauge enamel wire, 6.25 inches effective diameter, 18 turns each, 36 turns total; bandswitch provides either series or parallel coupling to provide Low band and High band tuning based on Tongue's approach; impedance taps (High Band: 100%, 75%, 64%, 50%, and 28%; Low Band: 100%, 72%, 50%, 28%) on coils to provide matching to diodes.

Diodes - Two (one marked FO215 and one marked 3502) in parallel.

AUDIO:
Matching - Reproduction of Steve Bringhurst's Ulti-Match circuit.

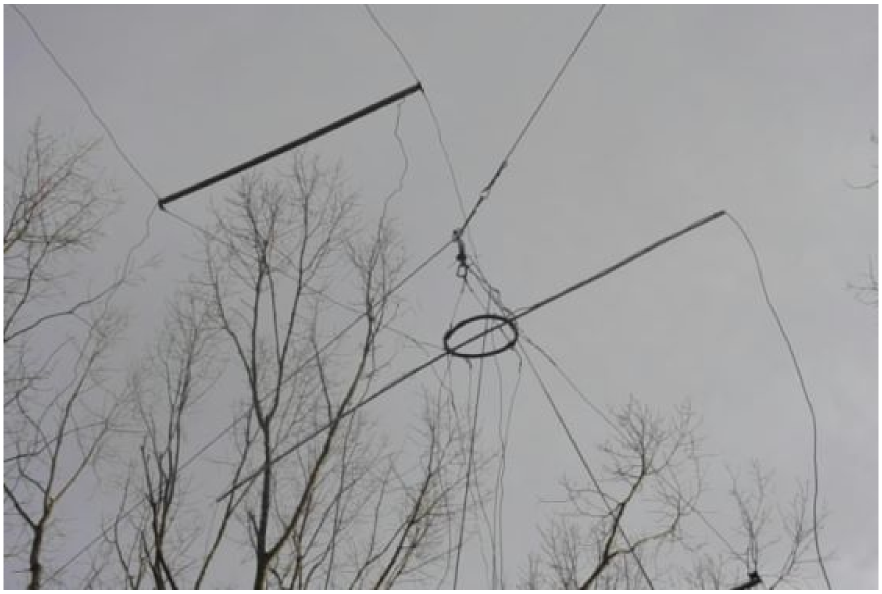
Headphones - Two Automatic Electric GH-66919 elements (manufactured 1942) out of a military handset and a set of Steve Bringhurst's enhanced SP cans.

NOTES:
The basic set is similar to my 2004 contest set. The primary > differences: larger Rook coils with larger gauge wire, hotter diodes (thanks to Steve Bringhurst), 20 uA meter, and new front panels.

I determined optimum AMU settings across the AM BCB for each antenna prior to the contest. These settings were reasonably reproducible during the contest, even when it rained!

The capability to switch among three antennas was great, especially between vertical and horizontal polarization. A station that was uncopiable on one antenna usually would be loader on one of the others. Generally, I used the vertical the most, but I noticed on several occasions that I could hear a station on one of the slopers when I could not on the Tee.

By the way, I live on a city lot that is 85' wide and 165' deep. However, I am blessed with having very good relationships with my neighbors on both sides and with a wooded area directly behind my lot. After Hurricane Ivan destroyed all my antennas (three oak trees ranging from 50' to 80' tall fell!), both neighbors allowed me to re-erect the Slopers across their backyards. Also, the 90' leg of the Tee ran well into the woods behind my lot.



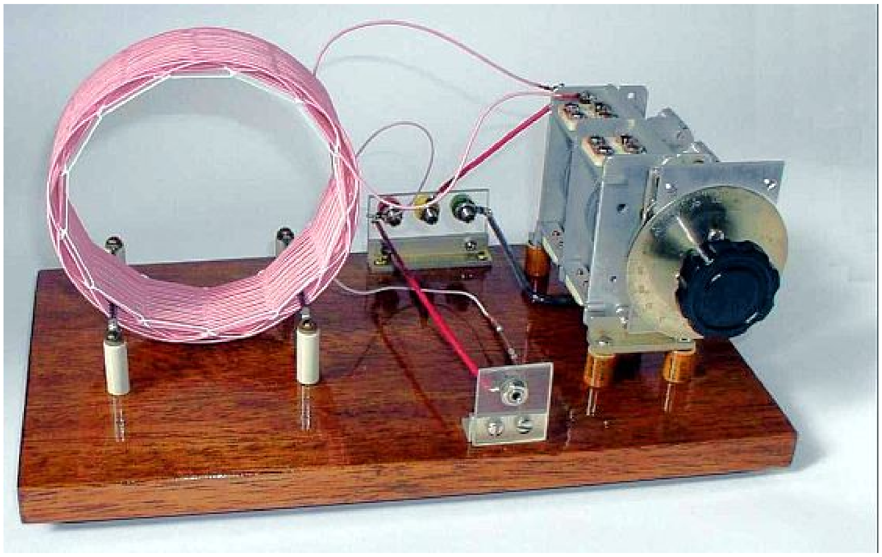
ANTENNAS:
(1) Tee, 46’ tall; top-loading legs consist of two parallel wires spaced 38” and run 90’ to Southwest and 40’ to Northeast. The vertical core consists of a cage of four parallel wires spaced 12” apart. To provide broader bandwidth I added two vertical wires from each of the top-loading legs (spaced 4’ from core center), and one additional vertical wire on Southeast and Northwest sides (spaced 4’ from core center). All of the vertical wires are connected at the base and series fed with a single wire.

(2) Sloper, 118’ with far end at 50’ and station end at 8’, oriented toward East-Northeast

(3) Sloper, 130’ with far end at 50’ and station end at 8’, oriented toward West-Northwest

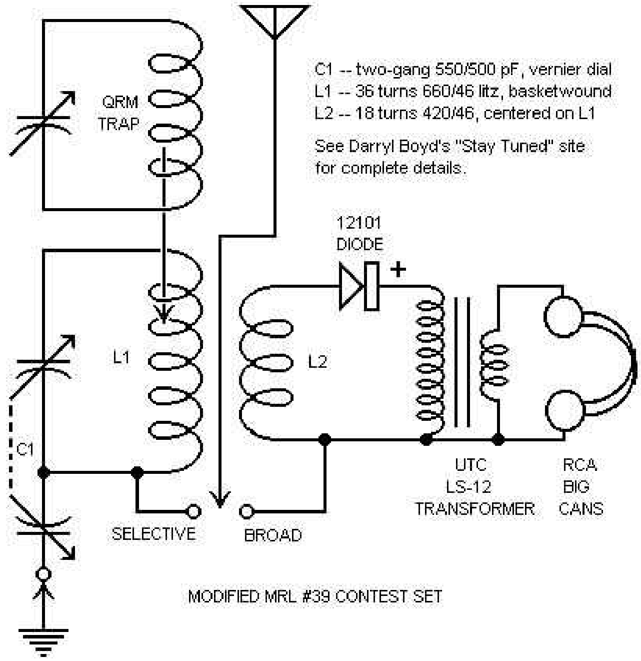
Ground system: Ham station ground - six ground rods interconnected and connected to shack with two quarter-inch copper straps; supplemented by one 8’ ground rod directly under the Tee and 4-4’ ground rods under the wires dropped from the top-loading legs, all inter-connected with copper wire; both ground systems connected with a run of copper braid (salvaged from old RG-8) over a #10 copper wire. Radials are 17-gauge aluminum electric fence wire; used 12 radials with lengths from 30’ to 135’ (one radial attached to the city water system!).

Mike Tuggle



As it turns out, all loggings were made in the 'BROAD' configuration.

The DX gods never really smiled this time, maybe an occasional smirk. Still, I guess I can't complain.



C1 -- two-gang 550/500 pF, vernier dial
L1 -- 36 turns 660/46 litz, basketwound
L2 -- 18 turns 420/46, centered on L1

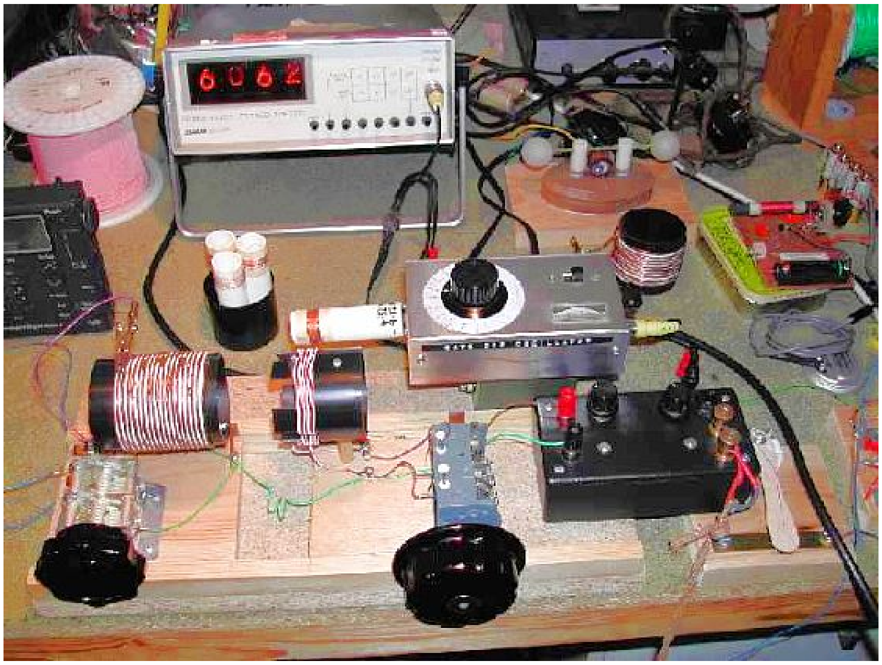
MODIFIED MRL #39 CONTEST SET

Philip Miller Tate (Ge_Whiz)

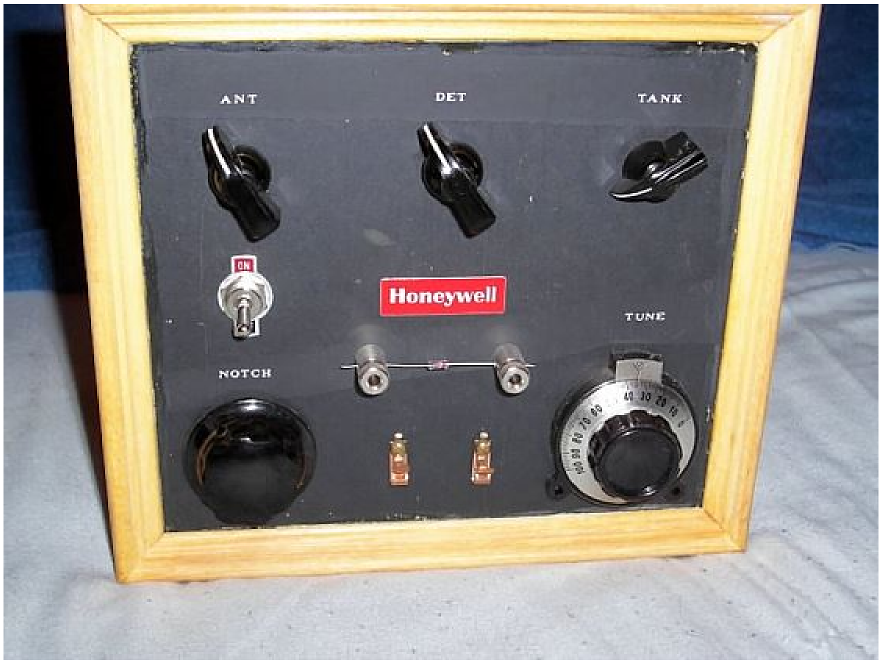


The radio is a loose-coupled set. The antenna coil is heavy solid copper wire, 16 turns on a two-and-a-half inch diameter ABS drain pipe, tapped every other turn. The aerial is coupled in via one stage of a dual 120 + 120pF variable capacitor; the other is in parallel with the coil. There is no earth connection – the set works better without it – but the earth level is hard-wired through to the detector coil. The aerial itself is a total of 120 feet of wire running from the end of the house, 50 feet to the shed roof and back at an angle of about 35 degrees to the opposite end of the house, average height 20 feet above ground. Note that there is no vertical section, as the radio is located on the top floor of the house.

The detector coil is eight turns of 660/46 Litz wire with an inductance of 5uH, wound on a five-point rook former of the same ABS pipe, in parallel with a 350pF variable capacitor with three-turn gearing. The combination tuning system covers approximately 4-15MHz. The detector is an AAZ18 germanium gold-bonded diode. Output is to a Select-to-Match transformer system and thence to a pair of DLR-5 military balanced-armature headphones.

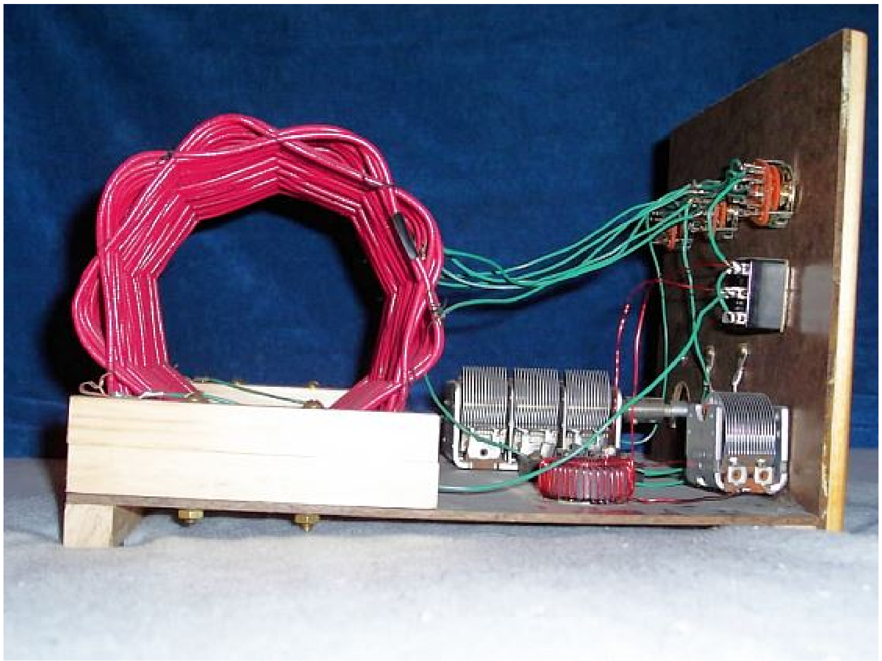
Alongside the detector coil, as shown above, is the plug-in coil of a homebrew gate-dip oscillator connected to a Racal Nixie-tube digital frequency meter. By carefully adjusting the tuning of the GDO, the dip of the detector coil resonance can be found to about +/-20kHz accuracy, and used to find the station on the spotter radio, a Sony IC100.

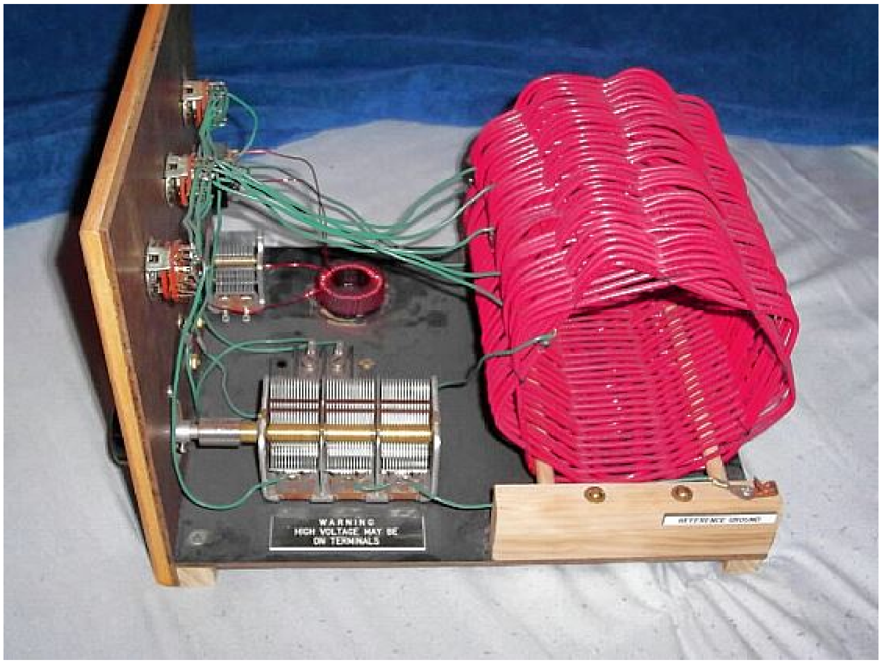
Rich Shivers



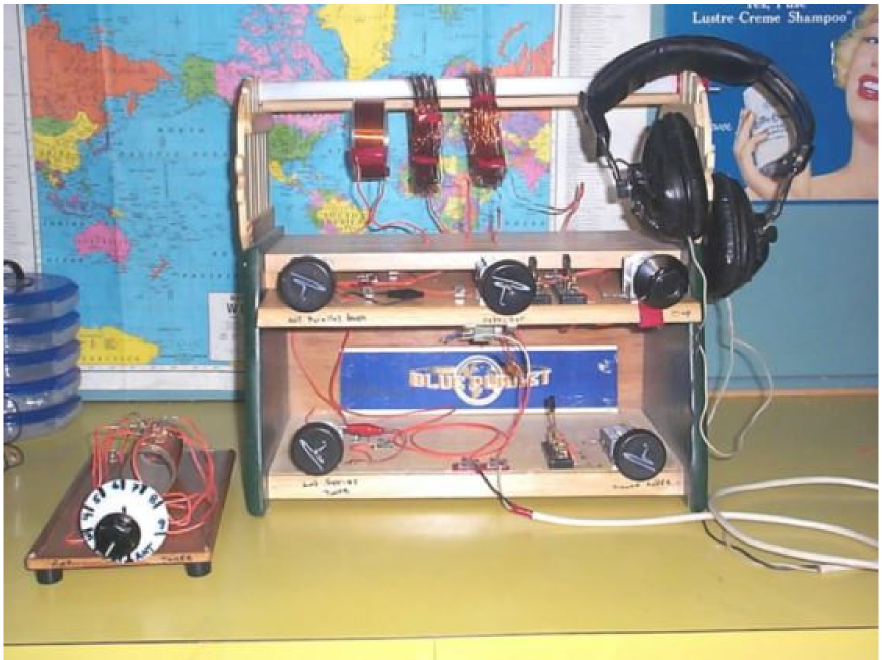
I have followed the comments on the Rap 'n Tap board, and agree that conditions were not very good this year. Compared with last year my total station count was down and DX stations were just not there. Disappointed, yes; did I have fun, yes.

I am using a large tapped single coil set. It's an air core basket weave coil 5" in diameter, about 8" long. 66 turns of 14awg THNN household wire. It is tapped every 11 turns with separate rotary switches for the antenna, detector, and capacitor. Normal arrangement has the antenna and detector tapped near the bottom of the coil. By tapping down the tank circuit I can band-spread the top of the band for improved selectivity. The tuning cap is a three section 400uh unit. One section across the coil, the other two section in parallel from the bottom of the coil to ground. A 8 to 1 vernier dial drives the tuning capacitor. Between the antenna and tank coil is a wave trap constructed of a tank circuit and a coupling coil. Both trap coils are wound on a single ferrite core. Headphone are WE 509's. Detector is a 1N34. Antenna is a T arrangement; 40' across the roof, with an 8' lead-in, the other leg drops straight down for 12'.





Lou Dayich



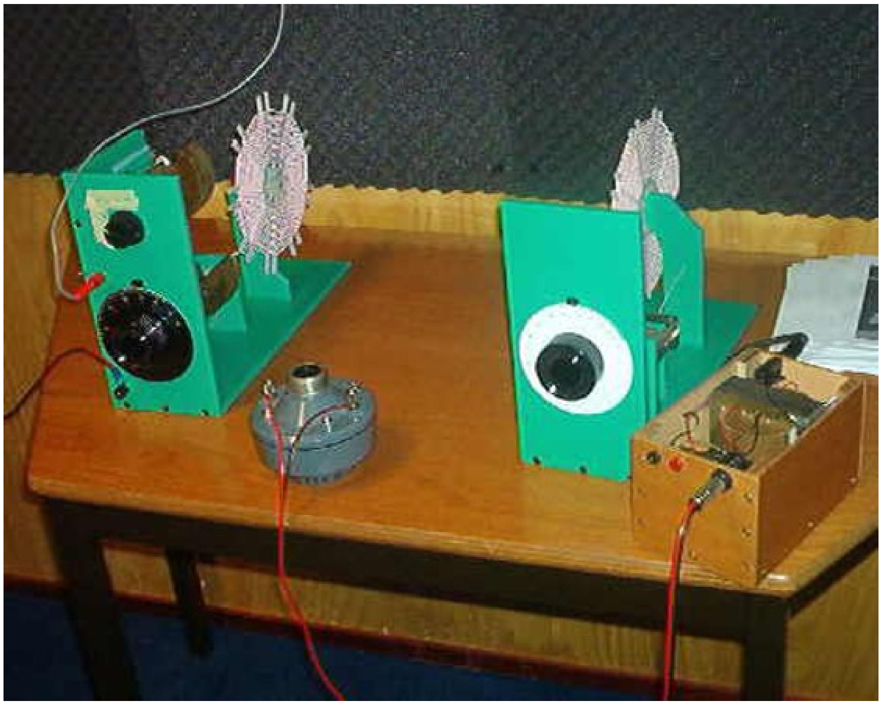
I built a new set for this year's contest. Some components were transplants from the 2004 contest. This set uses three coils and 5 variable capacitors, you will also notice three knife switches that were used in various parts of the receiver.

The antenna coil is aproximately 30 turns of close wound magnet wire, apx. 3 inch diameter. The caps (top and bottom) on the left side of the receiver provide parallel and series tuning to the antenna coil. The alligator clips on both caps allow the caps to be easily taken out of the circuit. The detector and trap coils are apx 4.5 inches, 9 point basket weave coils. During most of the contest, I actually set this up with the trap in the middle and the set became triple tuned.

The detector coil is a dual gang Russian variable cap (built in vernier) and the knife switch allowed me to use one or two gangs for detector tuning. The bottom right cap uses the same type of cap and knife switch arrangement for ground leg tuning. The top right cap was fitted with a 10 to 1 vernier reduction for wave trap tuning. The phones are sound powered cobbled from some USI elements and a bogen matching transformer can be seen mounted under the "shelf". I used two diodes at different times during the contest, an FO215 (solo and configured in a Hobbydyne set up) and a schotty diode.

As you can see the radio case "was" a wooden breadbox and the door came off making a nice shelf. On the left side you will see a stand alone inductive antenna tuner, this helped during the contest and is really great for casual listening; with the caps configured in a certain fashion, I can tune 5 or 6 of my regular stations just by clicking the rotary switch on the tuner. I had more points and station count with this year's receiver, but due to high winds just prior to the contest lost my best antenna. I ended up with a sloper apx 80 feet long and about 25 feet at its highest. Lots of fun! It is great to see all the radios that been built.

Dick Kleijer



My receiver is build with separate unit's.
- the antenna unit
- detector unit
- audio transformer unit

The coils are made with litz wire 660/46 and are wound on very low loss polypropylene formers. The diode is a double shottky diode, type: HSMS282K. The transformer unit has a input impedance of 1600 k.Ohm, this is about the impedance of the detector LC circuit, so there is maximum power transfer.

As loudspeaker, I use a driver unit of a horn loudspeaker. The antenna is a 22 meter (72feet) wire, with the highest point on 18 meters (59 feet). On the picture, you see the antenna wire coming down from the top of the mast. More info about my receivers, you will find on my website: crystal-radio.eu

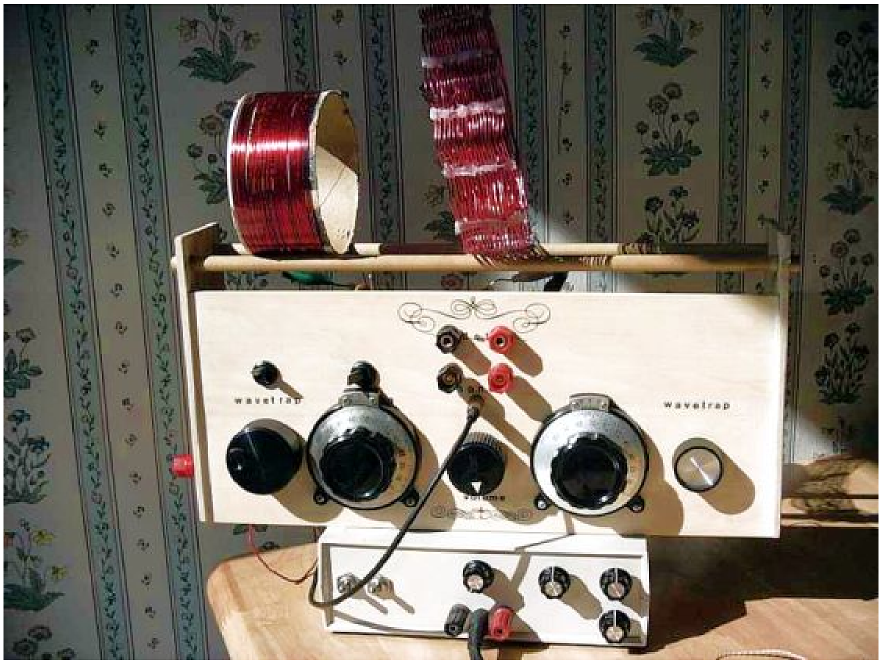
Crystal Radios Of The 2006 Contest Entrants

Page 1

Charles Pullen (Chuckster)



Station count was a little better than last year. I modified the metro to have a tuggle tuned antenna, added vernier drives for the antenna and detector capacitors and installed an old 5 gang fm tuner to give the detector circuit a selectable bandspread cap.

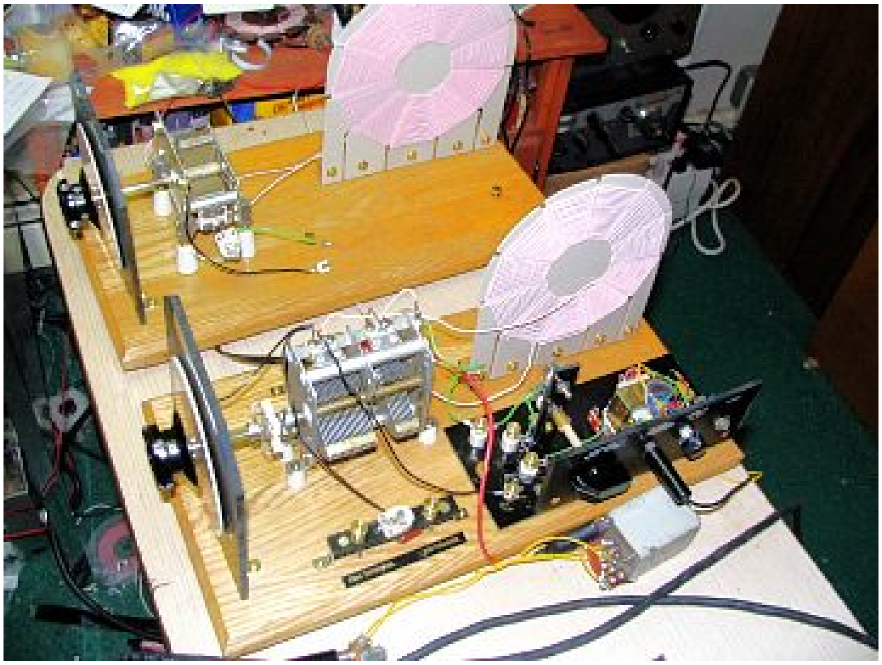
The antenna is a sixty foot inverted L approximately thirty feet up, and the ground is two four foot copper clad grounding rods tied together. I slapped to inline wave traps together to help tame the bandmasters. I used my copy of Steve B.'s ultimatch for impedance matching, and my head set was two philmore xtal earplugs connected to the ultimatch with a radio shack mono y adaptor.

My coils were severly mismatched and pretty beat up as seen in the photo of the "improved metro", but just ran out of time before the contest began to conjure up a new set of coils. I plan to replace the coils with toroids next year ala the TK2 circuit. Experiments with the toroids look really good but again didn't get them ready in time for the contest.

I'm pleased with the results I got considering the shape my coils were
in and the really warm weather conditions we've had …

Chuck

Dave Schmarder



Here is the web page with additional comments, etc. Dave's 2006 Contest Log Dave's #63 Radio

...I used my #63 set with the crystal detector on the antenna tuning unit board...The other coil is a wave trap circuit.

The receiver is a loop receiver with sides of 26x38 cm (10x15 inch). The wire is 660x0.04 mm litz wire (660/46).

Number of turns: 16

The two transformers have a total primary impedance of 300 k.Ohm. The headphone is a modern 2x32 Ohm type (Sennheiser HD202).

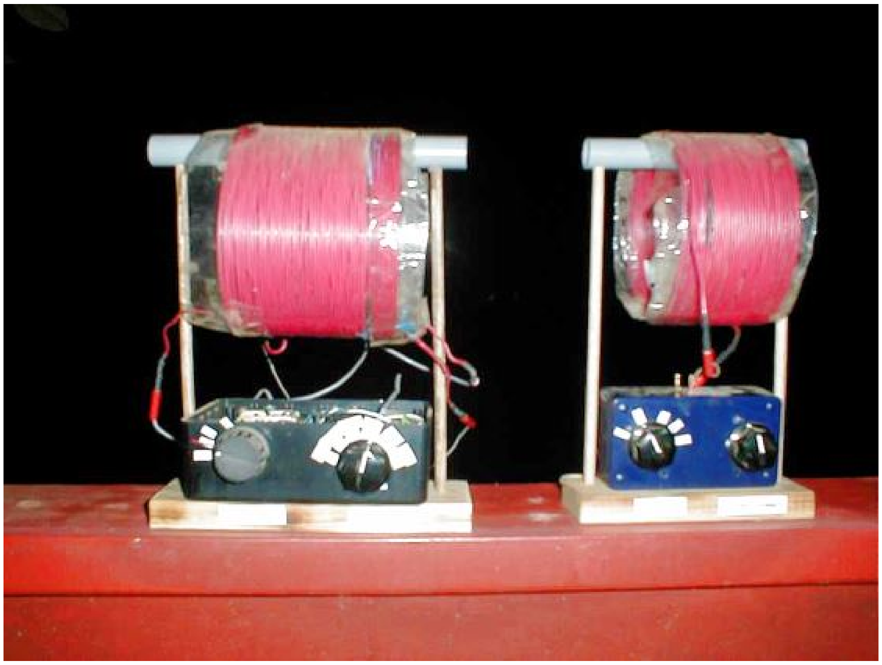
Doug Herigstad



The radio I used is a double tuned set with the coils space wound on a 5” form. (3 liter soda bottle). I built a variation of Owen Pooles’ “Project Radio” on his website.

The antenna coil is 35 turns of space wound solid 18ga hookup wire. I used a combination parallel/series Tuggle tuner with separate 365pf vcaps with the series vcap in the ground path instead of between the antenna and primary tank. This gives me kind of a band spread.

The secondary or main tank vcap was pulled from an old battery set and has a 6:1 vernier built in. The main tank is 47 turns of space wound 18ga solid hookup wire on a 5” form. Only the antenna circuit is grounded to a cold water pipe.

The detector coil is solid 18ga wire wound on a 4” ferrite rod and fastened on the inside of the main tank. The detector itself is a 1N34A diode connected through a 39K ohm resistor bypassed with a .1 mylar capacitor connected to the white lead of a Bogen T725 transformer.

The headphones I used were the elements pulled from a discarded hearing impaired telephone series wired into a set of shooters muffs. These sound elements are much more sensitive that regular telephone elements. They work the best on the 375ohm tap off the Bogen. Much better than my 2000 ohm Newcomb magnetic headset.

The antenna itself is 12ga stranded wire 50’ high and 100’ long on the horizontal part oriented east to west. The far end is the west end …

Crystal radio with typical connections for a long wire antenna and good ground connections. The diode is connected for weak signals and moderate selectivity.

I've made a few minor changes to the schematic …

(1) The fixed value cap is 250 pf instead of 1000 pf.
(2) The fixed resistor is 100 k instead of 82 k.
(3) I used an audio transformer plus a set of "big cans"...instead of the Xtal earpiece. (my skull is still distorted from those big cans) I think it'll still work without the fixed capacitor and resistor if I go back to using the Xtal earpiece. This would leave me with a set made from just four parts. I may try running it, in that fashion, next year.

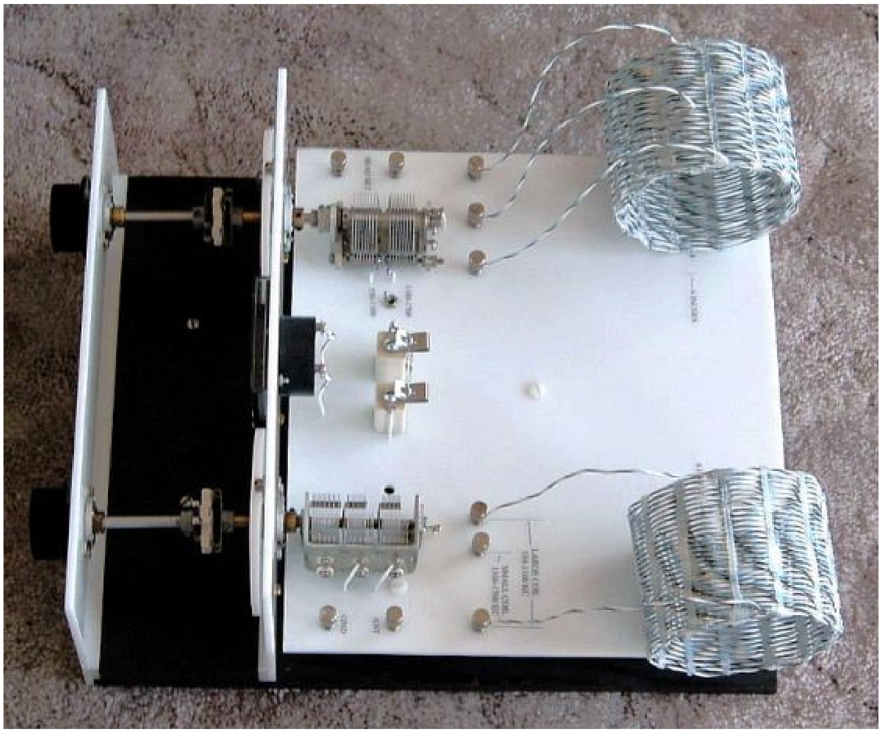
The SUPERCRYSTODYNE

I decided to get serious about the 2006 crystal radio contest and make the maximum commitment to do my best. I knew that I could do better than what I did in the 2005 contest. I wanted to see what a maximum commitment would produce. I started the day after the 2005 contest ended. The following is commited, devoted, crazy, or whatever you want to call it. The following documents over 400 hours spent toward this goal. After all, I'm retired and have plenty of time. What better way to spend it?

First thing was to build a new and better crystal radio that had the maximum efficiency that I could possibly put into it. The design would use the same basic circuit as I had been using. The coils had to have the highest Q possible. I needed a test instrument to measure Q. Thank you Ebay for allowing me to purchase one. Now to get some good wire to use. I purchased some different guages of stranded silver teflon wire. Thank you

Ebay again. I wound many many coils. I found the proper size for maximum Q at the frequencies to be received. No larger or smaller wire size is better. No larger or smaller coil diameter is better. No more or less turns of wire is better. Maximum Q is found. Now, one pair of coils in the receiver will not maintain maximum Q all the way across the broadcast band. I use two different sets of coils. One set for 530-1100 kc. One set for 1100-1700 kc. Now I have maximum Q across the whole broadcast band! These coils are the basket weave type held together with hot glue. They are air core coils using 22 guage stranded silver teflon wire. The two sets of coils can be swapped on the radio in less than 60 seconds.

Both of the variable capacitors that I use have porcelain insulation for the stator plates. The range of tuning must cover as much of the 180 degree range of the variable capacitors as possible. This must be done for both sets of coils with no critical lossy switches or taps on the coils. This was accomplished by using dual section capacitors and a couple trimming or padding fixed silver mica capacitors as necessary. The only tap on either coil is one on the secondary coil for the detector crystal. The position of that tap was determined by actual on the air listening for maximum selectivity and sensitivity in that order. The support for all RF parts is white 1/4 inch thick plastic. All wiring in the radio is made using stranded silver teflon wire.

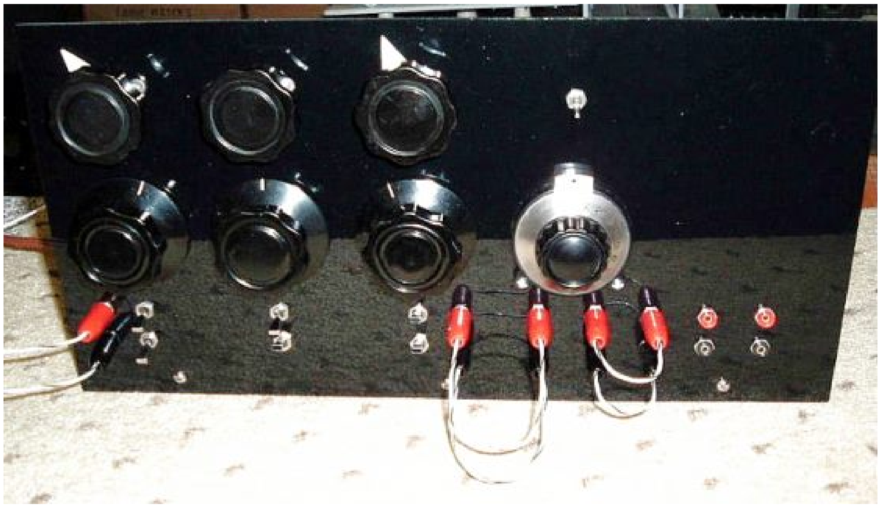


Now I had to have calibrated dials to quickly and accurately go to any frequency. Each of the two tuning shafts pass through the two panels. Each has a six to one vernier attached to the panel. So, each shaft has a 36 to 1 tuning reduction! On each shaft between the two verniers is an insulated flexible coupler. This isolates the tuning knobs from the RF circuits of the receiver to eliminate hand effect capacitance to the receiver. On the front of the rear vernier I placed a four inch diameter plastic disc. This disc is directly fixed to the shaft of the variable capacitor. On this disc I have paper dials calibrated for both coil sets. Each coil set uses a different colored ink. They are held on by double sided tape for easy removal. Thus, I can remove and make a new one in about a half an hour.

The detector is two parallel 1N34 diodes. They were selected for maximum sensitivity to a weak signal by on the air testing. I have a 50 microampere meter in series with the diode detector. A signal of less than 1 microampere is 100% readable. I am about 700 km from Chicago and Denver. It is not unusual for KOA or WBBM to come in at a full scale reading of 50 microamperes.

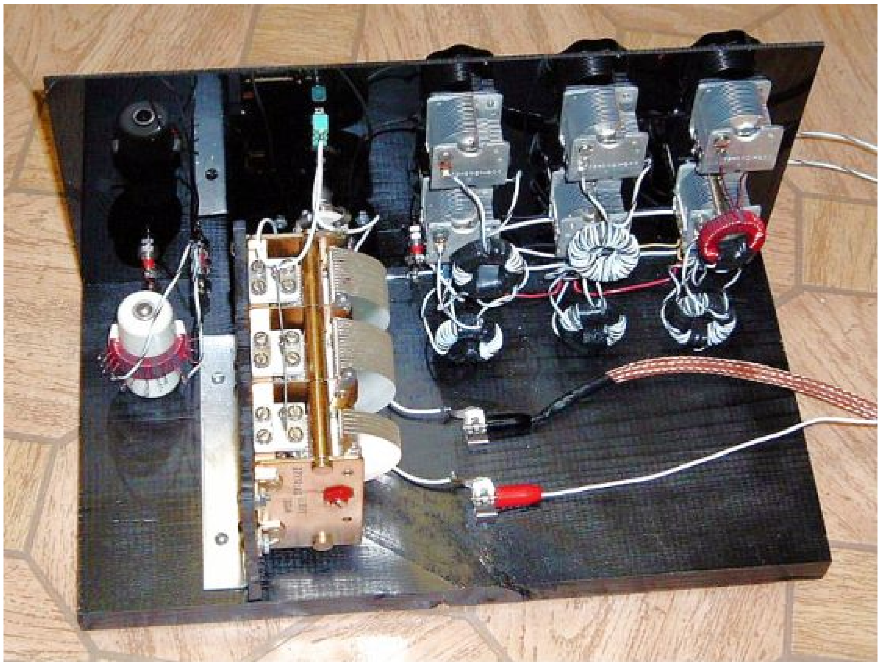
The headphones that I use are unique. I started with two USI balanced armature low impedance elements taken from an old sound powered handset. I first took them apart. I removed the coils. I took all of the wire off of the coils. I rewound them using super hair fine wire from a 6000 ohm sensitive relay coil. Each headset coil now measures well over 2000 ohms dc resistance. They were installed into a cheap, but nicely padded, headset that I already had. They are very sensitive. I also like the frequency responce of them as they reproduce higher audio frequencies better than the lows. The lows tend to be "muddled" on crowded frequencies.

Last summer was antenna experimenting time. I put up, tested, and took down more different sizes, lengths, heights, and orientations of wire than I can remember. Needless to say, considerable time was spent on this aspect of my endeavor. What I wound up with was a wire about 200 feet long that generally runs east and west. It is up 40 feet at the east end, 60 feet up at a point 120 foot west of that, and then sontinues 80 feet southwest of that ending up 25 feet above ground. The down lead comes off at a point close to the 60 foot support. All wire in the antenna is 18 guage stranded silver teflon wire. I have a ten millihenry choke to ground at the listening bench. Before I put that on, I saw 3/4 inch sparks from the antenna.



Designing filters to kill local stations became a must. I have a one kilowatt station only two kilometers from me. The Q meter came into use again. I ordered a number of each of three different sizes of torroids from Amidon. The coils for the traps are designed for maximum Q at the operating frequencies. I needed five for the top of the band and only one for the bottom of the band. They are wound using 22 guage stranded silver teflon wire. Each has a small 365 pf capacitor in parallel with it. There is a small winding on each for coupling. These small coupling windings can be put in or out of series with the antenna with a flip of a switch. Any number of traps can or can not be used at any time. They are all mounted on plastic to preserve their Q. These traps work very well and tune very sharp. This filter unit is a separate unit from the crystal radio. Also on this unit is a variable capacitor with poreclain insulation and silver plated plates. It is used to trim the antenna when needed.

By now, I was getting a good start on my quest. Next up was getting familiar with the broadcast band. This means lots of time spent listening. I listened almost every evening and night from the middle of August until the contest started in January. I estimate that I spend at least 300 hours listening and gathering information. I systematically monitored every frequency at all times of the day and night and carefully documented which stations could be heard at what time and on what frequency. The more times that I heard an individual station, I knew that on any given day there was a good chance of my hearing it. All of this information was used in the contest for maximum efficiency of the time available. This is critical because many stations can be heard only during a small window at sunset. Last year in the contest I didn't even listen at this time of day figuring that all of these signals were too weak to be heard. Wow, was I missing the boat or what? This is the best time to listen. I added almost 150 stations this fall to my all time heard list by listening during this period of the day. The information I then had for possible reception of stations was put to use in the 2006 contest. It worked well. 144 stations logged on the first day! The broadcast band conditions on that first night were the best that I have experienced in the past two years. They were nothing short of amazing. I put in 14 hours of listening and logging on that day alone. On every day of the contest I was by the radio for a couple of hours around sunrise, off and on during the day, and from 4 PM until about 11 PM. A person just can't miss that one more station logged. I put in at least eight hours of listening and record keeping for the contest for each of the nine remaining days of the contest. Almost 100 hours during contest week.



Total time spent for construction, preparation, and contesting turned into somewhere near 400 hours of fun. Every day listening is different. That's what makes it so interesting and fun. The band conditions were very good almost every day of the contest. Some nights produced longer

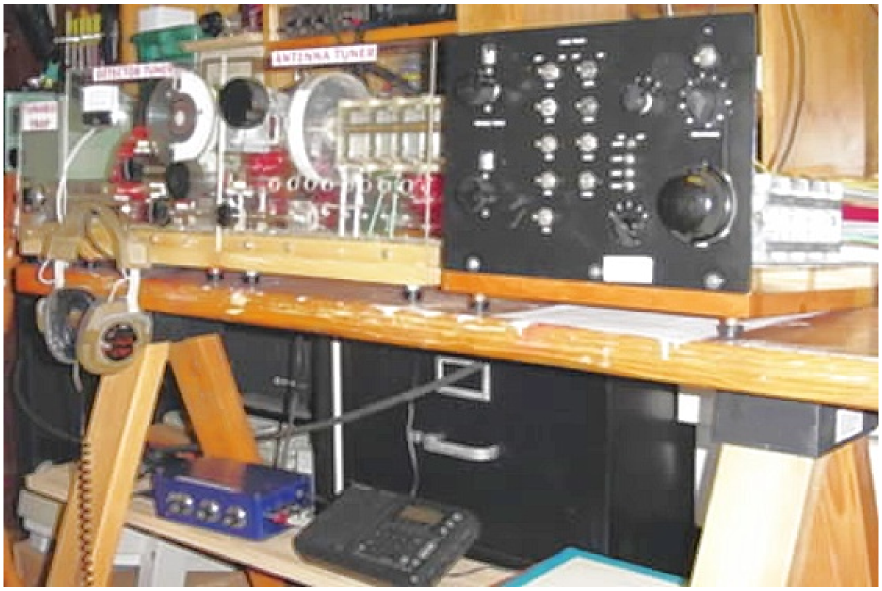
Lem Morrison



N4AHJ 2004 CONTEST CRYSTAL RADIO and OTHER INFO

ANTENNAS:

(1) End-fed inverted V long wire, 135 feet with apex at 40 feet, two 135 feet counterpoises under the antenna.

(2) Vertical, 48' tall Tee; top-loading consisted of two parallel wire spaced 38' and run 90' to Southwest and 40' to Northeast; 10 radials with lengths from 40' to 100'; series fed at base with single wire feed. Vertical core consisted of a cage of four parallel wires spaced 12" and two wires from each of the top-loading legs dropped down, spaced 4" from core center, and connected to base to provide broader bandwidth.

(3) Sloper, 118' with far end at 50' and station end at 8', oriented toward East-Northeast.

(4) Sloper, 130' with far end at 50' and station end at 8', oriented toward West-Northwest

Ground system: Ham station ground - six ground rods interconnected and connected to shack with two quarter-inch copper straps; supplemented by one 8' ground rod directly under Vertical antenna and 2-4' ground rods under the wires dropped from the top-loading legs, all inter-connected with copper wire; both ground systems connected with two runs of copper braid salvaged from old RG-8 coax. Radials were 17-ga aluminum wire (used for electric fences).

TRAPS:

(1) Tunable(1) - 2-section variable, sections in parallel, 240pF total; Rook coil with 18 gauge wire, 5.25 inches effective diameter, 47 turns; air-coupled to the Detector coil.

(2) Tunable (2) (located in Antenna Matching Unit) - both use 14 gauge enamel wire on FT-114A-61 cores and dual-section variables with both sections in parallel.

(3) Fixed (9) (located in Antenna Matching Unit) - 14 gauge to 22 gauge enamel wire on FT-114A-61 cores, silver mica fixed capacitors, and plated ceramic trimmers (one trap for each of the local "powerhouses"). Each link-coupled to the antenna feed to the set.

ANTENNA MATCHING UNIT (AMU):

One 4-section variable capacitor, four fixed capacitors (500pF, 1000pF, 2200pF, and 5000pF), and two coils (42 turns 14 gauge enamel on a FT-240-61 and 26 turns 16 gauge enamel on a FT-114A-61). All components switched to provide four matching arrangements: series LC, parallel LC, inductance only, and capacitance only. Both inductors tapped to provide 23 settings. An antenna switch is provided for switching between up to five antennas.

TUGGLE TUNER:

Capacitor - 520pF variable, 4 sections, 2 used in Tuggle arrangement, vernier is a surplus right-angle unit with a 25:1 ratio.

Coil - Two Rook coils with 16 gauge enamel wire, 5.25 inches effective diameter, 15 turns each, 30 turns total; bandswitched to provide either series or parallel coupling to provide Low band and High band tuning, a la Ben Tongue's arrangement; air-coupled to the Detector coil.

DETECTOR TUNER:

Capacitor - 420pF variable with home-made vernier with a 32:1 ratio (vernier constructed from gears salvaged from a VCR and a TV tuner).

Coil - Two Rook coils with 16 gauge enamel wire, 5.25 inches effective diameter, 20 turns and 21 turns, 41 turns total; bandswitched to provide either series or parallel coupling to provide Low band and High band tuning, a la Ben Tongue's arrangement; switchable taps (High Band: 100%, 75%, 50%, 25% and Low Band: 100%, 87.5%, 67.5%, 50%, 25%) on coils to provide matching to diodes.

Diodes - Three 1N34A Radio Shack equivalents, paralleled and matched for Forward and Reverse resistances.

AUDIO:

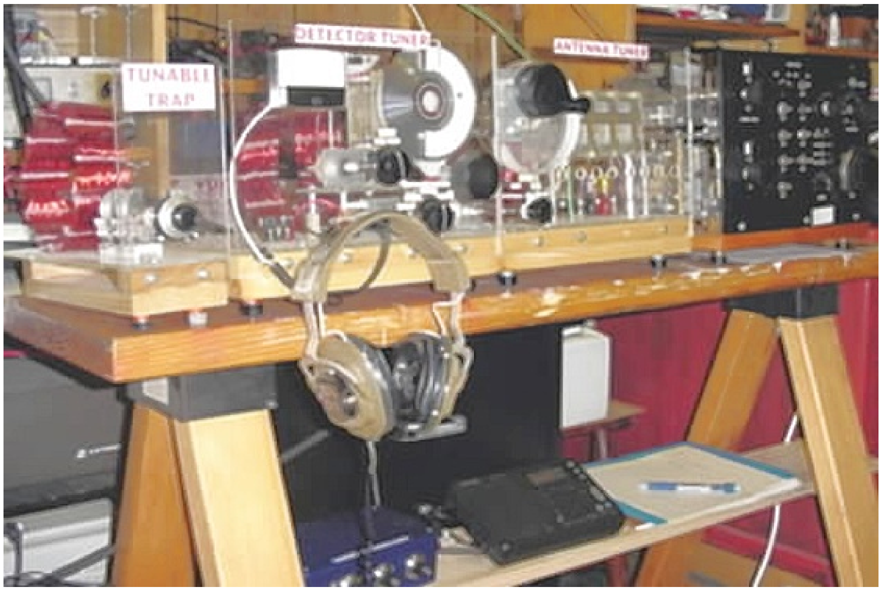
Matching - Reproduction of Steve Bringhurst's Ulti-Match circuit.

Headphones - Two Automatic Electric GH-66919 elements (manufactured 1942) out of a military handset.

NOTES:

The basic set is the same as my 2003 contest set. I moved the fixed traps from the Tuggle Tuner to the AMU and complemented them with two tunable traps. There were a number of times when I used all three tunable traps and one, or more, fixed traps!

I determined optimum AMU settings across the AM BCB for each antenna prior to the contest.



Notice the spotter set and audio matching unit on the bottom shelf.

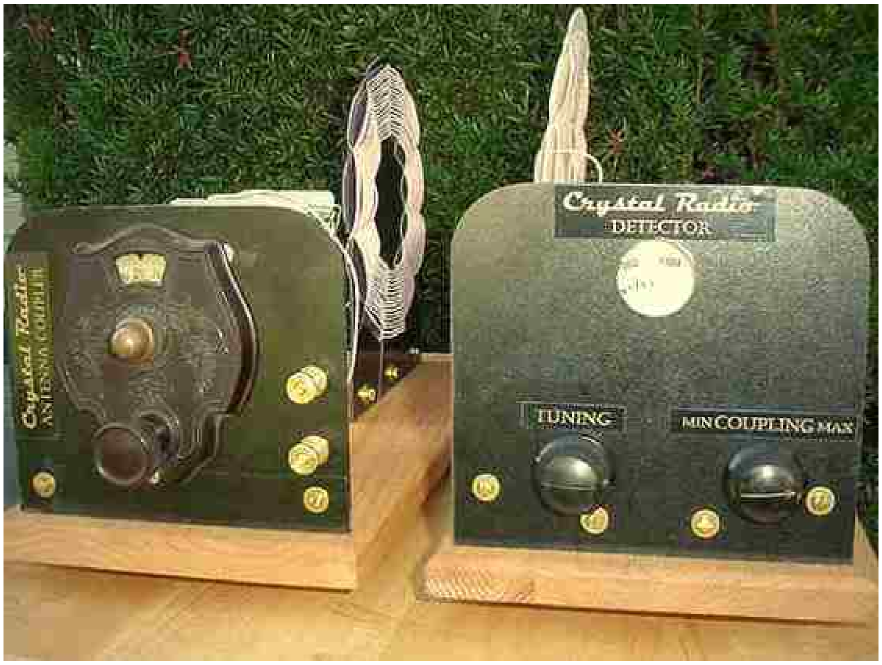
Dave Schmarder



These pictures and discussion are from Dave's site at: Dave's #35 DX Radio. His full description of this receiver is at his makearadio.com website.

This is the Crystal Radio to End all Crystal Radios. Hello there. Can't you just feel the tension rising? With this new radio I shift gears again. Large litz wire, high quality variable capacitors, schottky diodes. It won't get much better than this. Last night I am proud to announce that I heard KMOX in St. Louis on this radio. That is my furthest DX ever. I am sure that the ionosphere was hot and the wind was blowing my way, but a heard station is a heard station. Enough bragging and on with the show.

This radio is built in modular form. Mike Peebles gave me the idea when he had his modular crystal set published in the Crystal Set Society newsletter. The first part built is the detector. This consists of the main tuned circuit with my 660/46 Überlitz Coil. This is of my own design. I am a big fan of litz spider coils, and this is a big litz spider coil. I believe I hit crystal set heaven with this coil. The detector unit also has a selectivity / sensitivity control using a differential capacitor. Besides all of this there is, of course, the detector diode itself. I made a board with a three position link switch and places for three diodes to be connected. This allows me to easily compare 3 diodes in the same set. After the diodes is an audio output transformer and RC network. The 27 mh choke provides a DC return path for the diode circuit.

The variable capacitor is an old one made by National Radio. I made a wheel and fashioned a vernier tuning system with a grommet and a dowel rod. I get nice, slow and smooth tuning with this system. You can use a vernier dial instead if you don't have one of these capacitors in your junkbox.

The selectivity and sensitivity are handled by a differential capacitor and a piston trimmer. This system was first used in the Hobbydyne II circuit by Jim Frederick. The piston trimmer is for tracking adjustment. You adjust the piston trimmer until the main tuning needs no touch up after turning the differential capacitor. This is a breakthrough in weak signal reception on a crystal set.

The audio transformer matches the very high (100 k ohm +) detector circuit with the much lower impedance headphones. I am using a 100k to 1.5k ohm transformer. If you can find a high quality transformer, go for it.

This covers the detector section of my high performance radio. Next comes the antenna input circuit and maybe a wavetrap.

My tuning unit is now complete. The coil is made from 660/46 litz. The hub diameter of the coil is 3 inches. The coil form made from 1/16 inch styrene sheet is 6-1/2 inches wide and 7-1/2 inches tall. There are 33 turns on it for an inductance of 150 µH. The variable capacitor has 600 pf per section. Smaller ones can be used, however the low end of the band might not tune. You could probably get away with a 500 pf per section capacitor. This antenna tuner is wired as a "Tuggle Tuner".

Earlier I had used a 150 micro henry coil made from 40/44 litz wire. This worked quite well. One night very late, I scanned the dial and with this set up I heard 40 stations. Not bad for a September night.

The two units are placed next to each other. The coil distance for good overall operation are about 15 inches apart. Careful adjustment of the antenna tuner and detector tuning are required. The Q of these types of coils have been measured at over 1000! This ain't your grand pappy's crystal set.

If you build one of these, let me know how it plays for you. Happy crystal set dx. Dave, N2DS

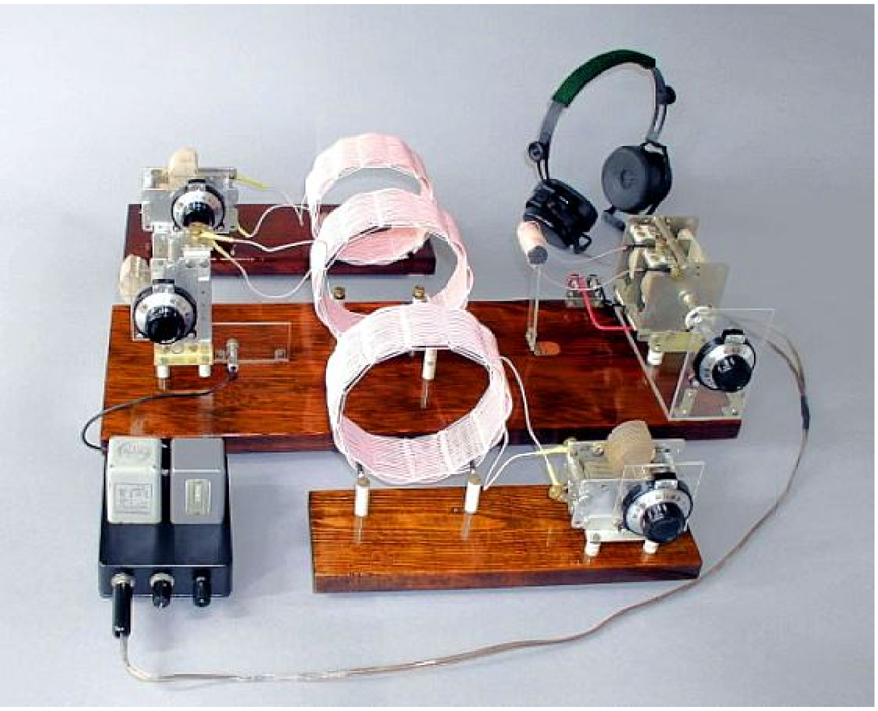
Crystal Radios Of The 2008 Contest Entrants

Page 1

Mike Tuggle, Lyonodyne-17, Open Class Entry

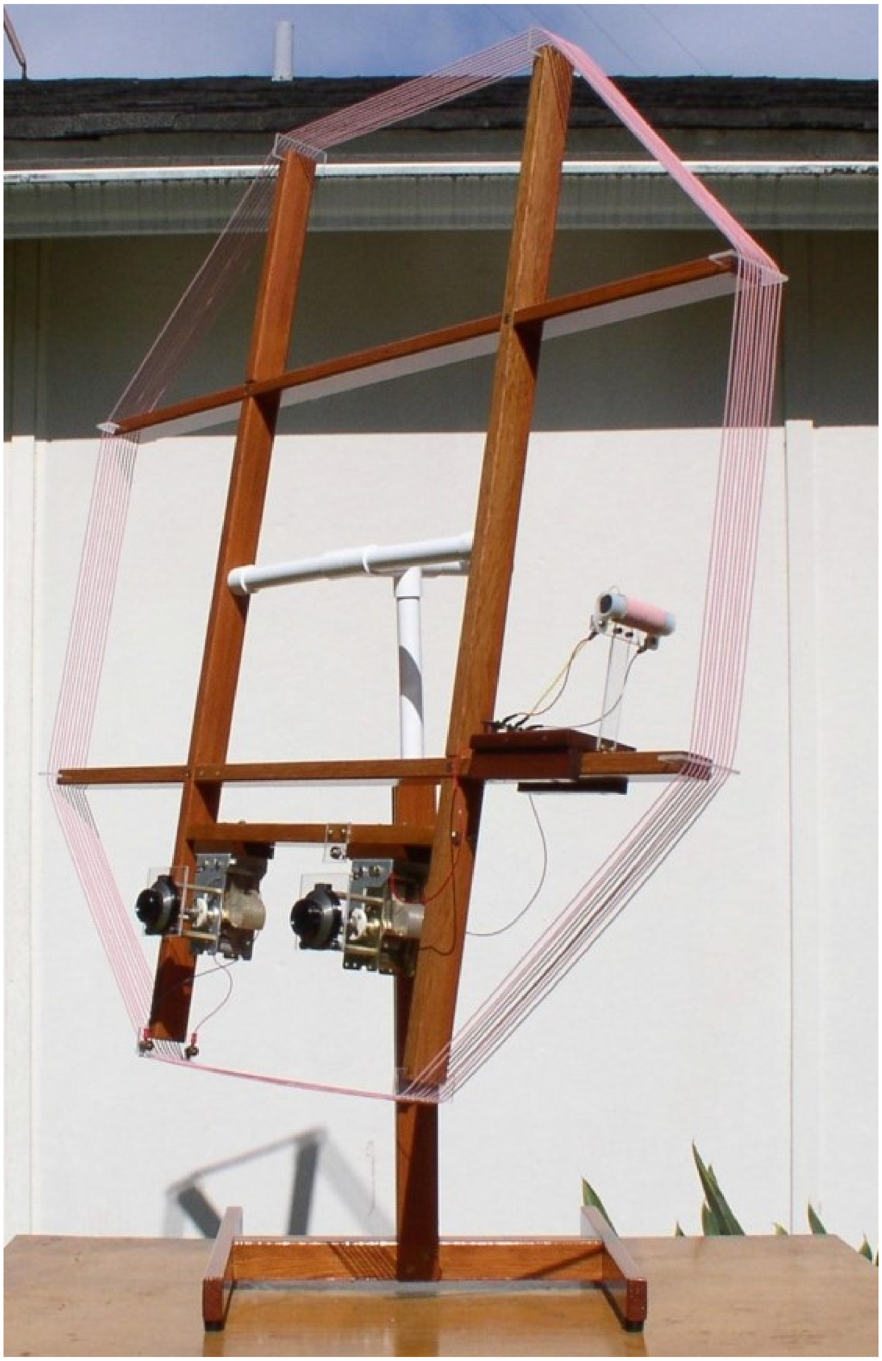
"So, the solenoid is king, the spider needs a make-over and the basketweave is done." - from a post on Rap-'n-Tap -

Right.



Mike Tuggle, Loop Class Entry

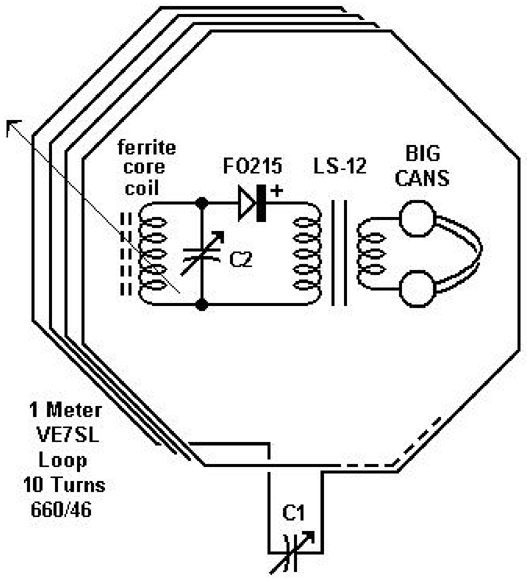
This double-tuned set is built onto a Steve McDonald (VE7SL)-design alt.-az. loop antenna.



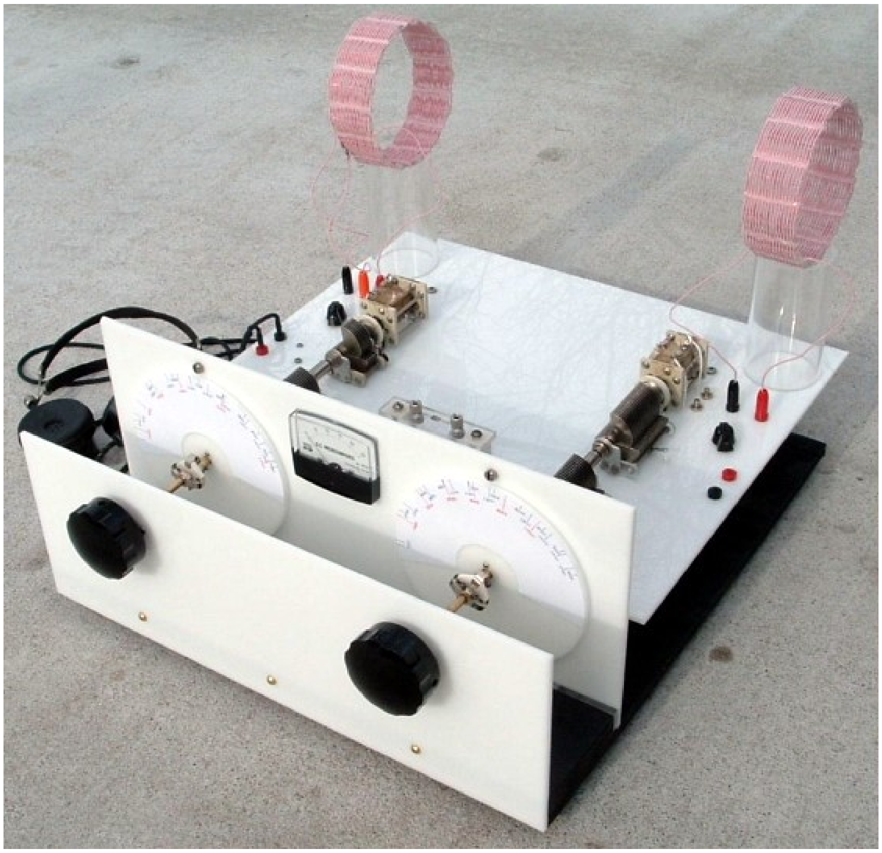
The ferrite coil slides on a loop strut to vary coupling. The idea was to see if mainland stations (2400 miles, and greater, away) could be heard here in Hawaii on a passive loop crystal set. The answer is, yes -- just barely. I really could have done with a bigger loop. Maybe next year.

Leading up to this circuit, I tried several designs using zero bias-voltage MOSFETs. A tapped ferrite coil or a pair of 5-inch diameter basket coils was used for gate and drain-source circuits. The basket coils were way over-coupled. None of the MOSFET circuits had promising sensitivity for possible mainland reception. Only by going to an ITT FO-215, kindly provided by Steve Bringhurst, could the big hop be made. This repeats my finding in last year's XSDX: The MOSFETs provide good selectivity but are not all that sensitive.

Twenty-five stations were heard, five of them DX on the mainland. Two of the DX stations were co-channel with strong local stations. I suspect the DX stations had exalted carrier help from the locals. This may be a potentially exploitable property of loop antennas: their characteristically sharp nulls can be directed to knock down strong local stations while, at the same time, leaving some carrier to exalt co-channel DX stations lying anywhere off the null direction. However, complete nulling the local station takes out everything.



Evan Haydon



I built a new crystal radio this year. I am now using 660/46 litz wire for my coils. One pair of coils for 530 kHz to 950 kHz. A second pair of coils for 950 kHz to 1700 kHz. They are basket weave with a five inch diameter. I wound solenoid coils of many diameters, inductances, and wire spacings with the 660/46 litz. None of them approached the measured Q of my five inch basket wound coils. My calibrated dials are six inches in diameter with two 6:1 verniers in series driving each dial. A third scale on each dial covers 1500 kHz to 1700 kHz. A pair of dual 8-60 pf silver plated porcelain insulated variable capacitors are switched in for 1500 kHz to 1700 kHz. Silver plated trimmer capacitors calibrate them to cover the dial. Overall selectivity and sensitivity are to the point that I really can’t complain.

This year’s contest was fun because the band was in flux all week. The first day had average to good conditions. The next three days were very poor with spotty receptions. The next two days had cold fronts pass through and stir things up. There were some unusual openings to the southwest. The last days were lively during the gray line times with some new stations for my all time heard list. That list is now 469 stations.

Here is a table of my activities during the 2008 contest.

DATE	#HRS	#STATIONS
1-18	13	168
1-19	13	35
1-20	10.5	18
1-21	7.5	9
1-22	7	15
1-23	9	20
1-24	7	9
1-25	5	8
1-26	6	16
1-27	9.5	3

Total of 87.5 hours and 302 stations. 291 stations identified. 11 stations not identified.
Total points: 556,834
Just in case you haven't guessed by now, I only eat, sleep, and work the crystal radio contest for 10 days in January.

The set-up is a standard double-tuned arrangement with hobbydyne coupling. I tried to learn from and use the info that folks have so generously posted on R'nT and Dave's forums. Wish I could "give back" as much as I've received.

Antenna: 200' inverted "V", apex ~ 40'. I "sling-shotted" a wire over the highest tree near the house.

Ground is a 4' pipe into damp soil + a wire into a pond.

The set is Double Tuned: Ferrite inductors 10" above table top on empty HDPE containers. Getting the coils up away from the table made a BIG difference.

Detector Coil: Vintage ferrite bars, 9x2, 1/8” sep, 35t cw 330/46, 120 µH. "Battradio" ferrite bars, 2 stacks of 9 (7 high+1 each side) Wrapped with packing foam. This is kind of a 1.25"x1.25", "squarish" coil. I used Used the recent posted Q info with the wire I had available.

Dual gang 10-410pf cap, series-or-parallel (ceramic DPDT switched). The switch in the tank circuit didn't seem to hurt selectivity. Two tuning ranges gave good mechanical bandspread (<25 khz/div @ max f) via Jackson Bros. ceramic insulated cap, + 48:1 vernier, 0-100 dials. The Tuning is VERY sharp - really need the verniers (8:1 dial x 6:1 planetary).

Tuggle tuned ATU: 0.5”x4” Amidon 61 rod, 50t cw 165/46, 203 µH (~best for this antenna). 4" Amidon rods give better Q than 7.5" rods. Separate 365 pf Jackson Bros. caps + verniers. I needed a 48:1 vernier on parallel cap - tuning is sharp.

Hobbydyne: ~ 17pf (ceramic air variable) + 27 mH; choke (Dave Schmarders'). Helped at high end but probably don't need it with these ferrite bars.

Diode: FO-215 diode, rd~258k. (Picked the one with largest rd.). I could switch-in schottky's etc, but this was best overall match.

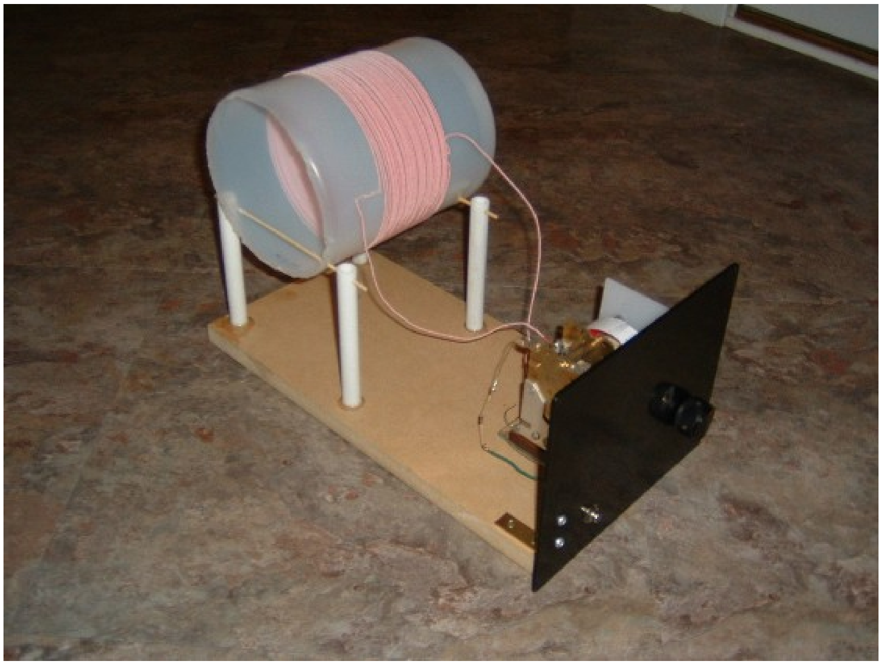
Audio: Dave's 200kUberformer + 500k Benny, shunted by 1µF. Two USI-UA1611-1 SP elements in series. (200k:2.5k).

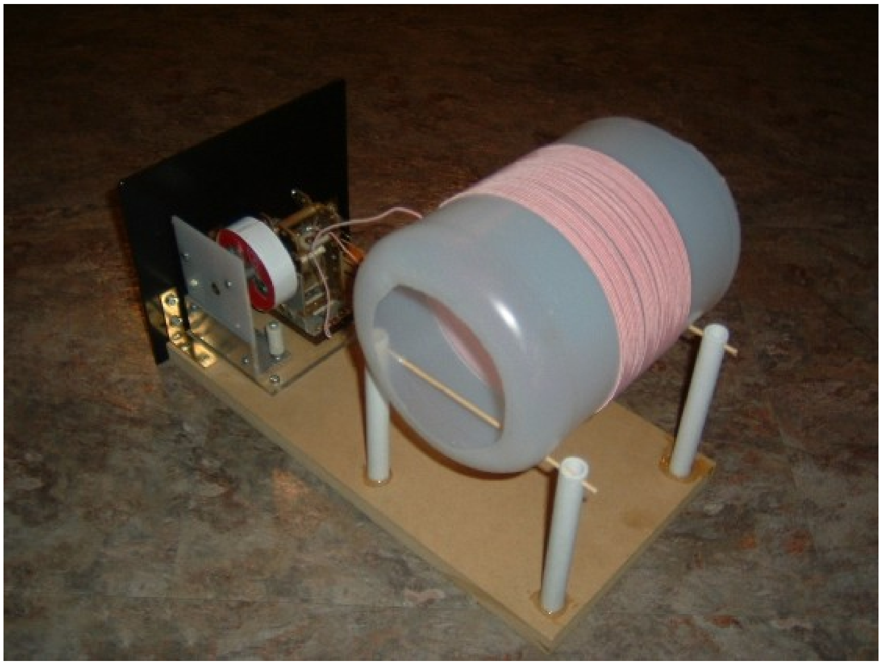
Calibration: Curve-fitted table of dial settings for every 10 khz of AM band. This is VERY useful for quickly pouncing on DX that pops up then fades.

Op-Aid: Master log of 300+ stations heard over the last 2 years. It really helps having frequencies paired to: ID’s, formats, ZIP’s, area codes, major roads, distance, grey-line, etc.

Spotter radio: YAESU FT-757GX.

Jack Bryant





I wanted to try something new this contest. My old friend, Lem Morrison, has had a lot of success with air core coils, so I thought I would focus on a similar set for 2008. I had conversations or e-mail exchanges with several friends on a set recommendations. This included Lem, Gil Stacy, Mike Tuggle, Dave Schmarder, and Steve Bringhurst. The set would use 660/46 Litz on some kind of form. Steve's recommendation of HDPE vinegar jugs with a six inch diameter was the final choice of coil form. I used bamboo skewers through the ends of the jugs as part of the supports system. These skewers went into vertical posts of CPVC pipe; The pipes were epoxied into the fiberboard bases. The arrangement is was I call “goal post support”. I set the jugs up several inches from the fiberboard to help minimize losses.

The radio has five basic building blocks: the trap, antenna tuning, detector, audio matching, and headphones. The trap was the easiest part since I used a toroid unit I had built a few years ago. It uses and FT114A-61 toroid with a five turn link opposite the primary winding. The ceramic insulated variable cap is tuned with a 5:1 ratio velvet vernier from a WW2 BC-375 tuning unit.

The antenna module uses a variable with a built-in 2: 1 vernier and is wired in series with the antenna. The antenna connects to the frame, and the stator connects to the top of the parallel tank circuit. This tank circuit consists of a “goal post” mounted Litz jug-coil and a ceramic insulated variable cap with a vernier, also from a BC-375 tuning unit. These verniers have a 50:1 ratio and use a right angle drive approach. A drum made from a peanut butter jar top provides basis for the frequency readout.

In many other radios I used a dual section cap for the combination of antenna and tank circuit caps, but I wanted additional flexibility. The approached used here worked out great. The separate series antenna cap was especially useful during daytime DXing. It allowed me to use a greater value of antenna series cap for higher volume on weak daytime stations as well as reduced series capacitance when needed for selectivity. The base of the unit is fiber board with a from panel made from a black plastic clipboard.

Next is the detector module with the goal post mounted Litz jug-coil, an FO-215 diode, and a Fair Radio “holy grail” variable cap. This unit also uses the same type base and front panel as in the antenna unit. I selected to use neither taps nor a contra- wound approach on the two coils, just continuous wound coils. I did add complexity by adding an additional eight turn winding between the Litz rope for biasing a zero- bias MOSFET. This was switched in and out via a panel mounted double pole ceramic switch. I had trouble with the MOSFET and switching arrangement and finally bypassed it, using only the diode detector.

A panel mounted phono plug allows connection to the remote audio matching unit. A length of video cable joined the detector and audio units. I build a version of Mike Tuggle's double transformer Stanley match, and it worked great. Mine was wired for only two impedance options. I used the high input setting almost exclusively. I also tried a Select-To-Match and single transformer Stanley matching units for use with the in-the-ear units, but the double transformer Stanley Match seemed to work as well or better than those.

The headphones required more attention than any other part of the radio. The many hours of listening in previous contests with heavy sound powered elements had taken its toll on the nerves around my ears. In the previous contests the irritation became quite severe, such that even one of my eyeballs throbbed with pain! I had mentioned this one Rap N Tap,and a received quite a number of suggestions.

Garry Nichols and John Davidson provided me with an in-the-ear Shure unit to test. Steve Bringhurst provided a set of British phones with a wire behind the neck for partial support and a cloth band over the head. I also tried some Koss and Realistic in-the-ear phones. I used both the Shure and Koss phones in the beginning of the contest. They were comfortable and worked fine, but were not nearly as sensitive as my old phones. Steve's phones were sensitive but were not comfortable. I finally settled on a helicopter headset with salvaged SP elements. The headset fit completely over and around the ears. While these were not as sensitive as my old set of phones, they were a reasonable compromise.

I have used a Realistic DX-398 for several previous contests, and I used it for this one, too. A neat trick is to bring the antenna matching unit near the DX-398. Sometimes the DX-398 needed this extra boost the hear the signal the crystal set was receiving!

I like to use computer logging as I go along, so I used my normal home PC for that. A four foot table from Lowe's and a comfortable chair rounded out the listening post.

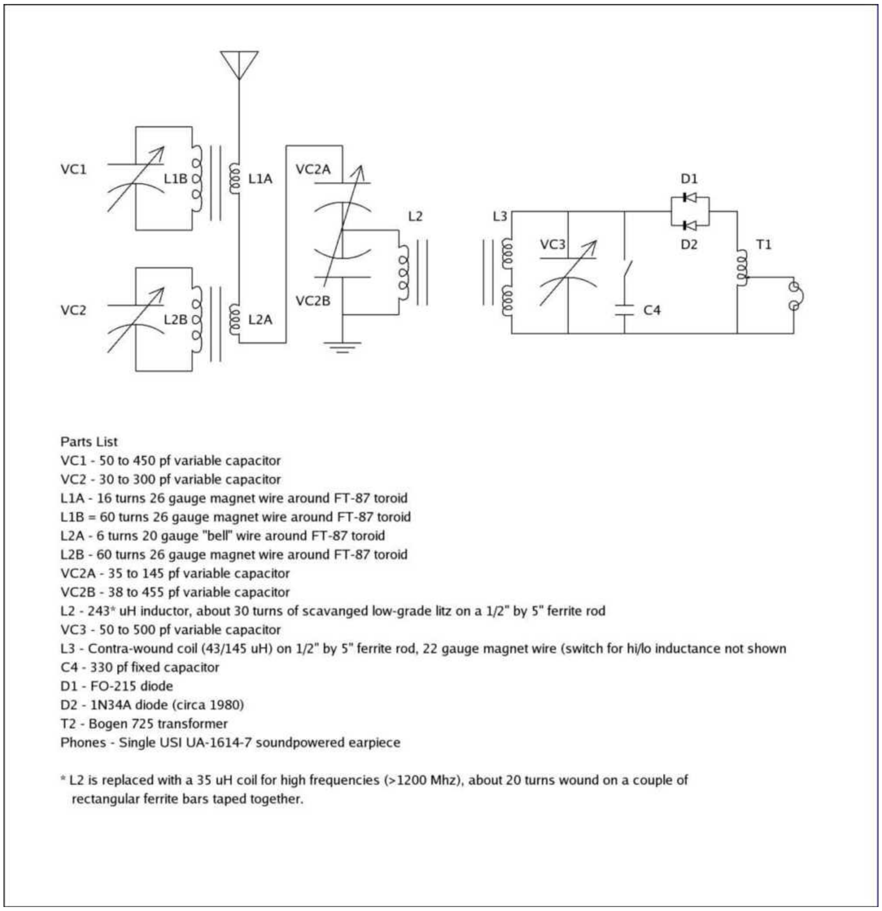
Crystal Radios Of The 2007 Contest Entrants

Page 2

Jeff Welty



Parts List
VC1 - 50 to 450 pf variable capacitor
VC2 - 30 to 300 pf variable capacitor
L1A - 16 turns 26 gauge magnet wire around FT-87 toroid
L1B = 60 turns 26 gauge magnet wire around FT-87 toroid
L2A - 6 turns 20 gauge "bell" wire around FT-87 toroid
L2B - 60 turns 26 gauge magnet wire around FT-87 toroid
VC2A - 35 to 145 pf variable capacitor
VC2B - 38 to 455 pf variable capacitor
L2 - 243* uH inductor, about 30 turns of scavanged low-grade litz on a 1/2" by 5" ferrite rod
VC3 - 50 to 500 pf variable capacitor
L3 - Contra-wound coil (43/145 uH) on 1/2" by 5" ferrite rod, 22 gauge magnet wire (switch for hi/lo inductance not shown
C4 - 330 pf fixed capacitor
D1 - FO-215 diode
D2 - 1N34A diode (circa 1980)
T2 - Bogen 725 transformer
Phones - Single USI UA-1614-7 soundpowered earpiece

* L2 is replaced with a 35 uH coil for high frequencies (>1200 Mhz), about 20 turns wound on a couple of rectangular ferrite bars taped together.

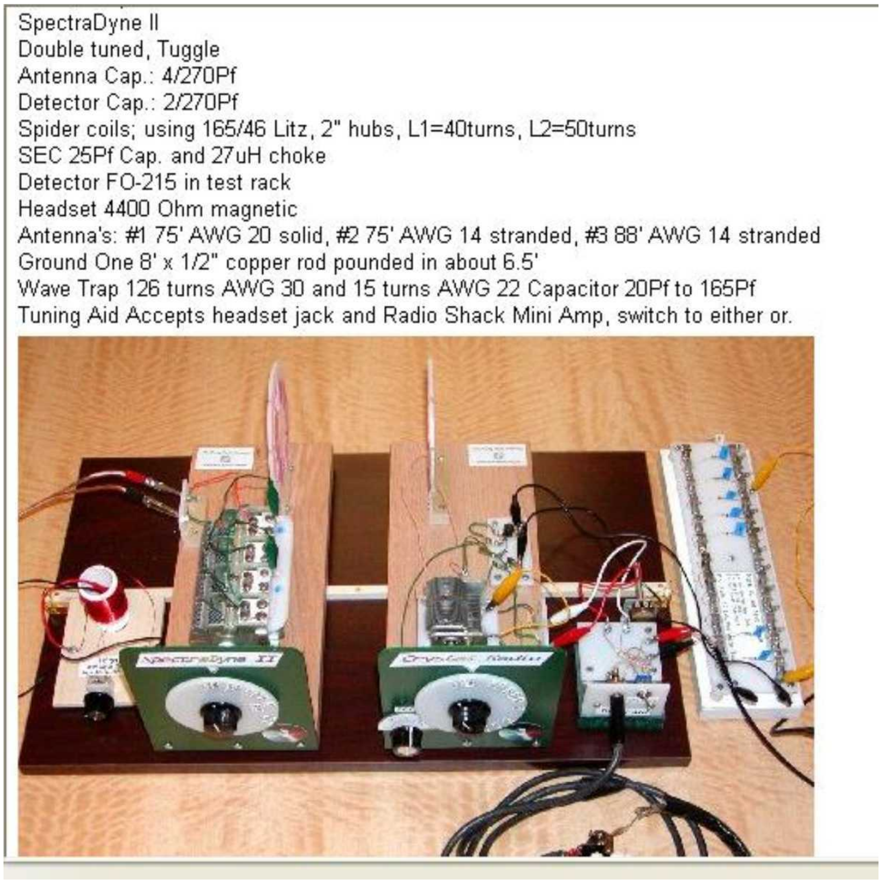
Click here for the large schematic view

The variable capacitor on the antenna coil is from a radio in that I remember being in my sister's room in the 1970's, (which I dismantled for parts sometime at the end of the 70's, and made my very first crystal set with), and the detector coil is wound around a ferrite rod from the first radio I ever owned as a teen age boy, also back in the 1970's, and died about 4 years ago so I scavenged the ferrite rod from it.

The basic radio is mostly built from parts literally scavenged out of other radios over the years. The only "new" parts are the bogen 725 transformer, FO-215 diode (thanks Dave Schmarder) and sound-powered headphones.

Strong memories in this set for me, and hearing stations fading in and out really brings back memories of the days when I'd listen to my radio, hearing far away stations and caught up in the wonder of it.

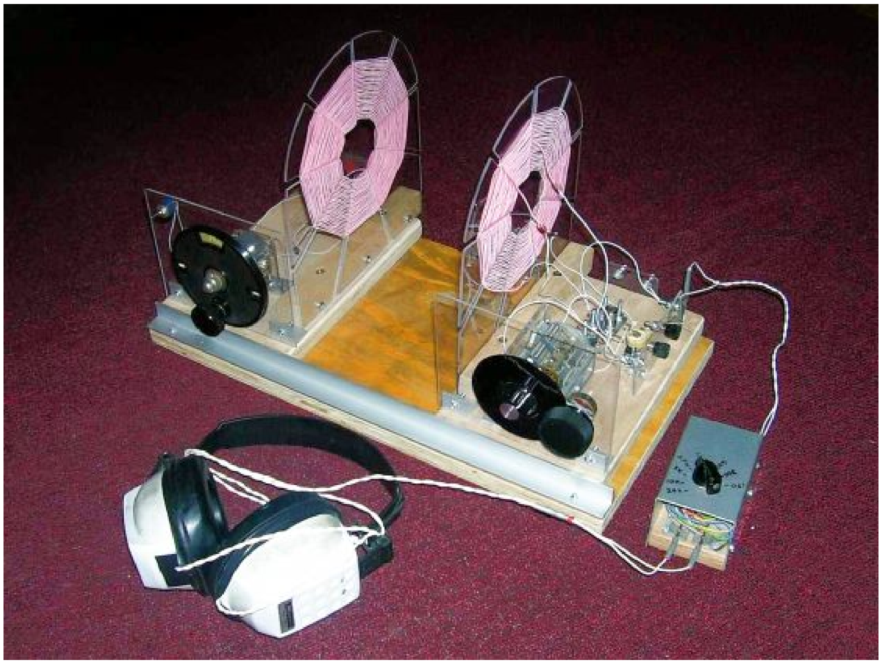
Otto Danby



SpectraDyne II
Double tuned, Tuggle
Antenna Cap.: 4/270Pf
Detector Cap.: 2/270Pf
Spider coils; using 165/46 Litz, 2" hubs, L1=40turns, L2=50turns
SEC 25Pf Cap. and 27uH choke
Detector FO-215 in test rack
Headset 4400 Ohm magnetic
Antenna's: #1 75' AWG 20 solid, #2 75' AWG 14 stranded, #3 88' AWG 14 stranded
Ground One 8' x 1/2" copper rod pounded in about 6.5'
Wave Trap 126 turns AWG 30 and 15 turns AWG 22 Capacitor 20Pf to 165Pf
Tuning Aid Accepts headset jack and Radio Shack Mini Amp, switch to either or.

Click for large view.

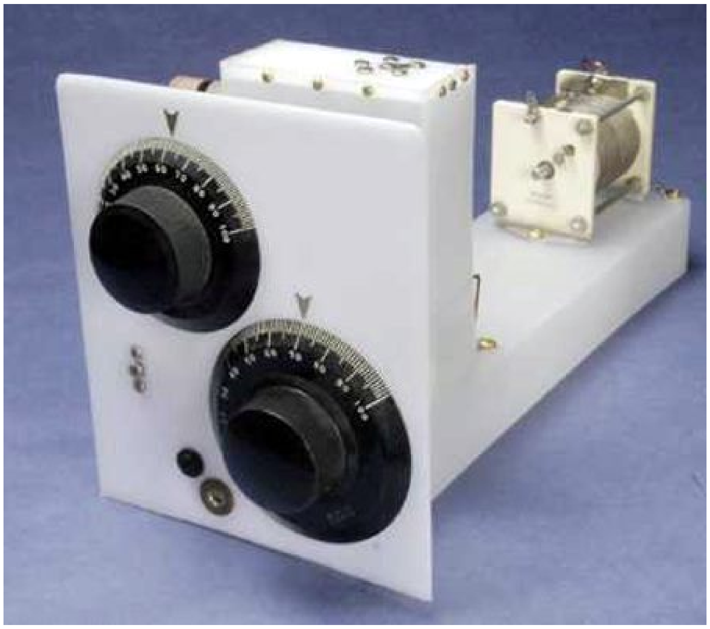
Peter Kertulla

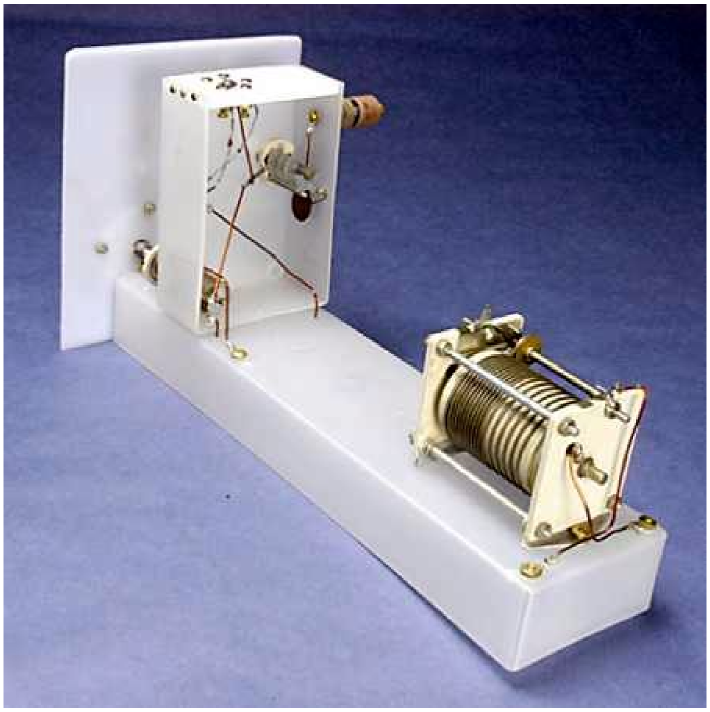


2007 CRYSTAL SET CONTEST SET

The rig this year is all new. It is double tuned with 660 litz spiderweb coils. Both capacitors use reduction drives for easier tuning. The detector coil was changed at the last minute to a contra-wound configuration…the jury is still out as to the impact this made. I think I may use separate plug in coils for HI and LO band next year. The antenna is the same as last year… 100 foot end fed up about 25 feet. Headphones are sound powered elements in a reused headset with a bogen transformer that has switched impedances.

Robert Golding





My short wave set is very simple.

It consists of a tank circuit composed of a small Johnson roller inductor with a small 100pf silver plated variable cap. I connected another small variable as an antenna trimmer and included a small trimmer to ground. It has a diode selector arrangement including a single generic Radio Shack germanium (black band) and choices of one two or three paired Schottky IN5711s. I found it necessary to add a bias attachment for the IN5711s.

I had an outboard Benny setup that plugs in between my matching transformer and the set. Therefore I added a tiny watch battery to the wiper and one end of the rheostat. The bias really perks up the IN5711 diodes.

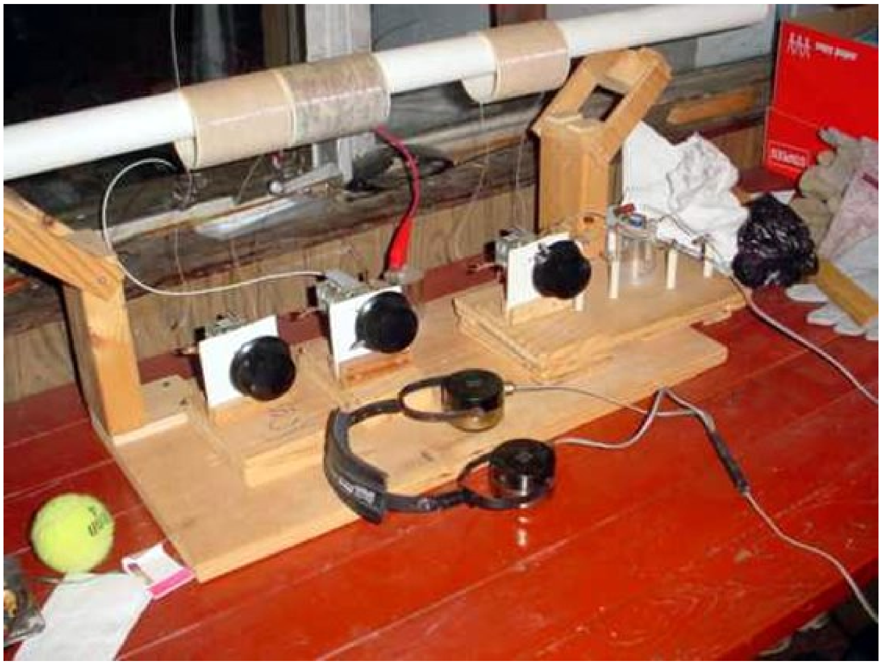
My headphones are Western Electric sound powered matched with a UTC Ouncer transformer.

The antenna trimmer proved to be ineffective. So, I tried Steve B's cap string which helps somewhat.

Naturally I wasn't quite ready when the contest started. So I got through the first couple of nights with the diodes still on clip leads.

I used a couple of small door knob caps for the antenna cap
string which is overkill, but I sort of like the look of it.

Steve Hewlett



2007 Crystal Radio Contest Radio Set Description

My 2007 contest set is the same as my 2006 contest set. The set has three coils which slide on a polystyrene tube. From left to right they are wave trap, antenna coil, detector coil. All three coils are space wound (one wire width spacing between turns) copper wire; #24 ga. for wave trap and detector coils and # 23ga. for the antenna coil. All three coil forms are 3" diameter polystyrene tube. The inductance of each coil is approx. 251 uH.

A single Jackson 365 pF VC is used on the wave trap coil and a single Jackson 410 pF VC is used on the detector coil. A dual Jackson 410 pF VC is used on the antenna coil in a Tuggle arrangement. The diode is a FO-215. A Calrad transformer and a "benny" is used in the detector circuit to match the SP headset - USI 1614 - I am using. The antenna is a 3-wire flat top aprroximately 75 feet long and 13-18 feet high. Ground is a series of three 8 foot copper plated steel rods driven all the way in the ground four feet apart.

January 2009

L1, L2, L3, L4 – 4 equal inductance spider coils (26 turns, 2" hub)
– all can be coupled by varying the distance between them, usually 2-3 inches apart.

C1, C2 – Johnson 100pf trimmer capacitor.

C3, C4 – MAX-GAIN capacitors. – 2 sections in parallel ≐ 600pf.

SW1, SW2 – 2 pole 11 throw ceramic rotary switch using only 2 throws for High + Low Band.
– switches coils between Parallel + Series.

SW3 – 2 pole 11 throw ceramic rotary switch holds many diodes alone + in parallel.

Note: High and Low band is affected by either the 100pf trimmer capacitors or the spacing of the coils. So to set the Band overlap trial and error will give good results.

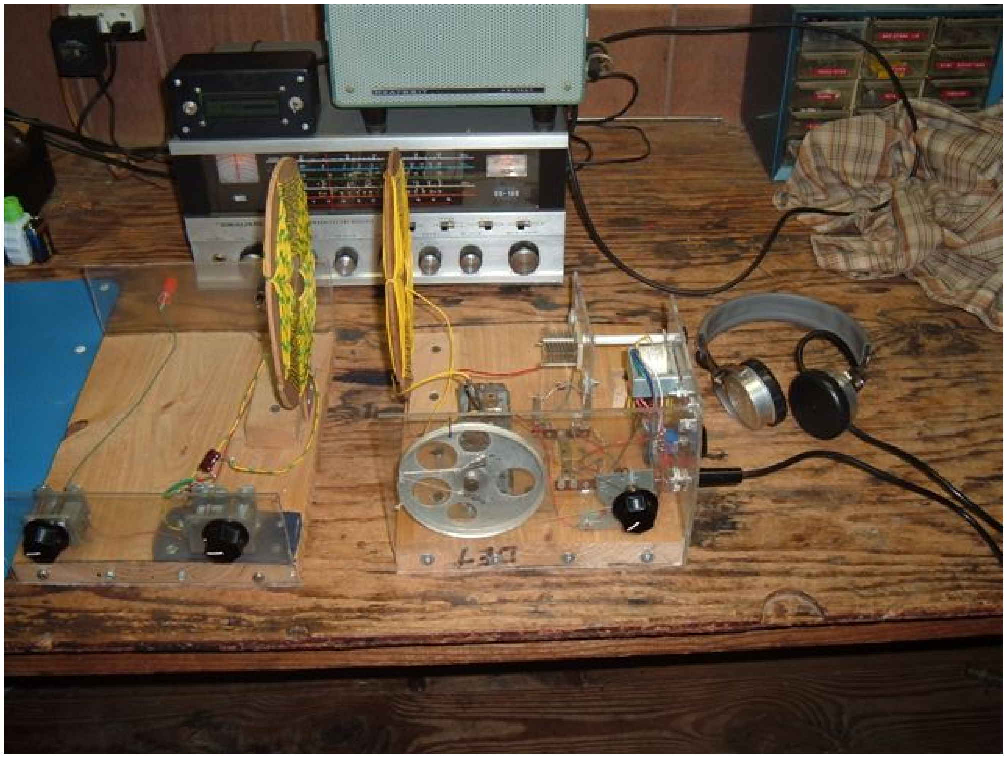
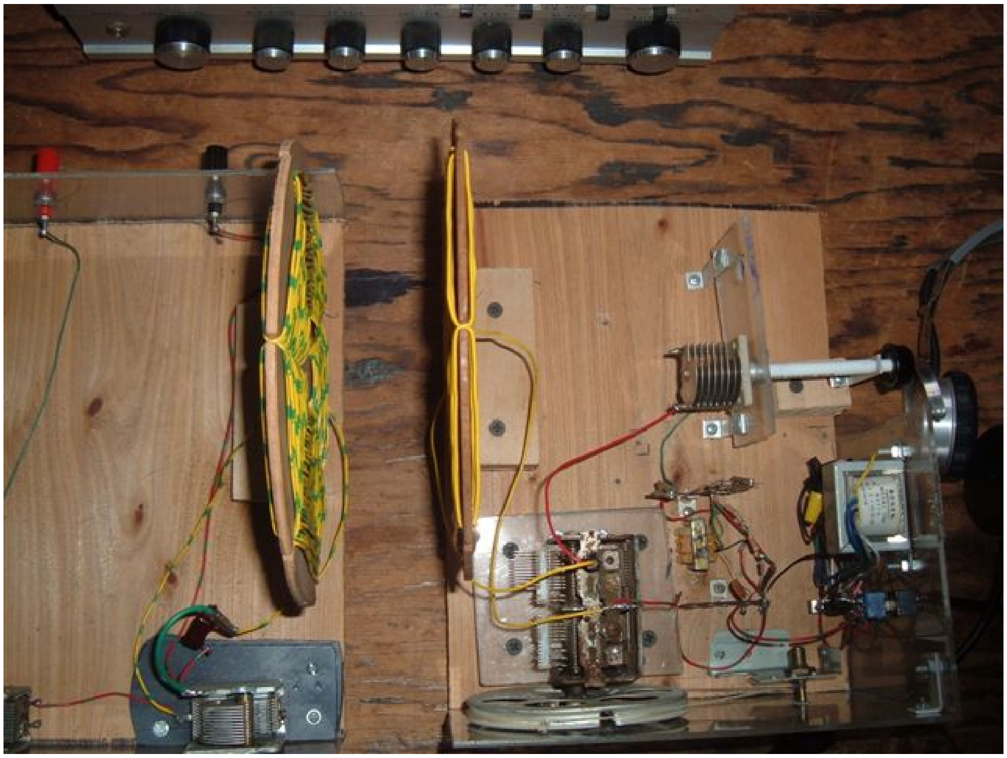
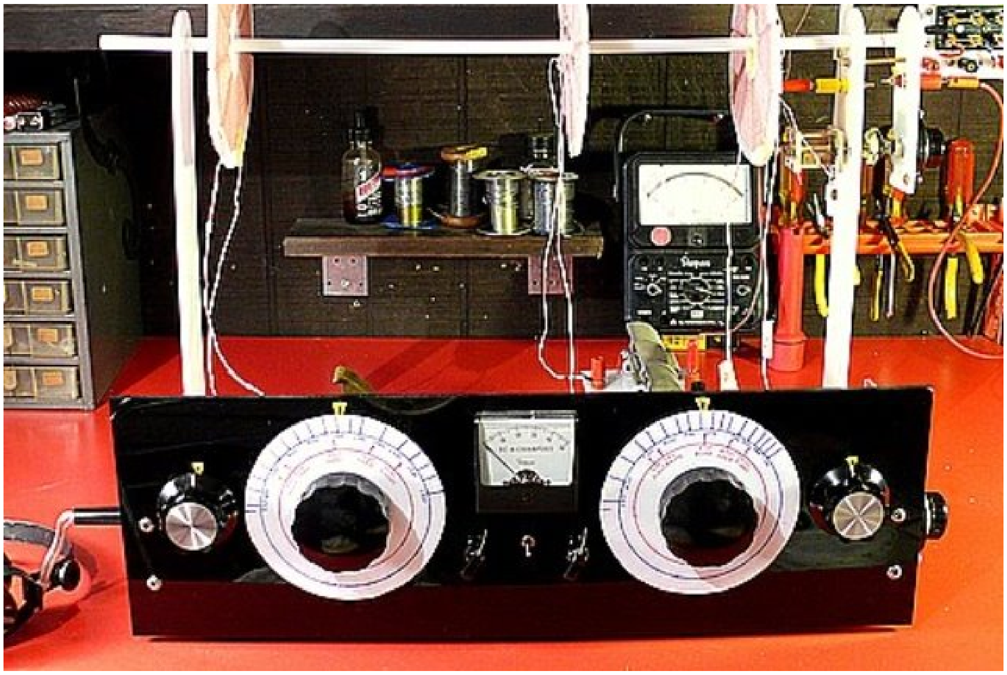
Glen Yarbro, Open Class Entry

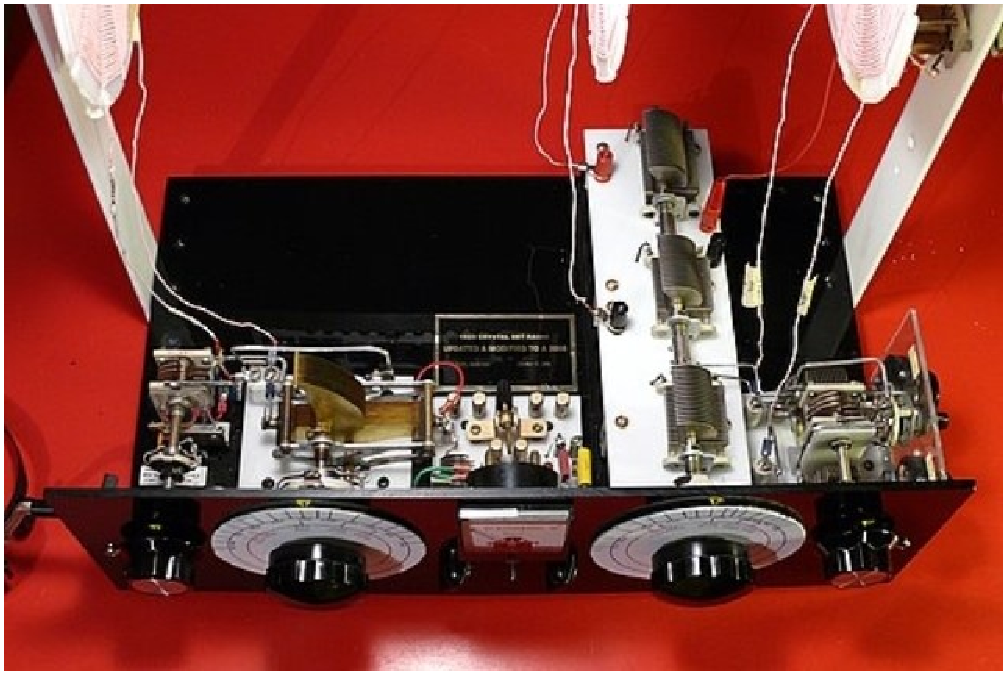




Radio : Dave Schmarder's #44
Antenna: 80m trap dipole, 30 feet high
Headphones: 4 k Navy phones
Coils were wound with 24 gauge Bell Wire

O. T. Anderson, Open Class Entry





This crystal set has been modified several times, the dials, Var Caps,and wave traps. Being a ham operator I really liked calibrated dials. Some of the local stations are in red.

The right hand 3 tuning caps are the Hammarlund type. The three caps which are ganged together is a "Tuggle" front end. The detector cap is an old ancient job from a very early radio. I modified it using HDPE to replace old brittle bakelite. I don't know how good it is, but it looks and feels great. It has good band spread down at 1200-1700 kc. The three coils and output Xformer I bought from that good man, "Dave".

The two right and left small caps are a band spread for about one station. It feels good to "rock" these a bit on a weak station. The "S" meter is a real help. A 3 position switch gives a off, normal and high position. I would not built a new set without one. Since this is a "crystal set" I had to put in new (old type) "Cat Whisker". Can you see it? It also has a place for 3 diodes.

My biggest trouble here in Broken Arrow, OK is 1170 kc. That's KFAQ, old KVOO, 50,000 watts. Big 50,000. Has three towers, see them from our house. I have 2 wave traps, one 1170 and the other is 740, KRMG. The switch and stationary caps are at bottom right. Works OK, but 1170 is still in the back ground.

Built up an external trap. It's still there. I accidentally found the trouble moving the set around one day, cleaning up. I nulled out 1170 as I had the set turned around so-so. Apparently the detector coil is a good antenna just like an antenna in a AC-DC radio. So what should I do? Relocate my operating desk, or better yet build a new set patterned after THE LYONODYNE, (which has wave traps on the detector coil).

My wife, Doris, K5BNQ, wasn't crazy about me being back in the shop. She said, when it gets dark, I should come in, build a fire in the fire place, read the newspaper, and have a big cold Pepsi or Mt. Dew. Then maybe she would give me some real good home made chocolate cookies!!! And some ice cream!!!

Who could beat a deal like that?

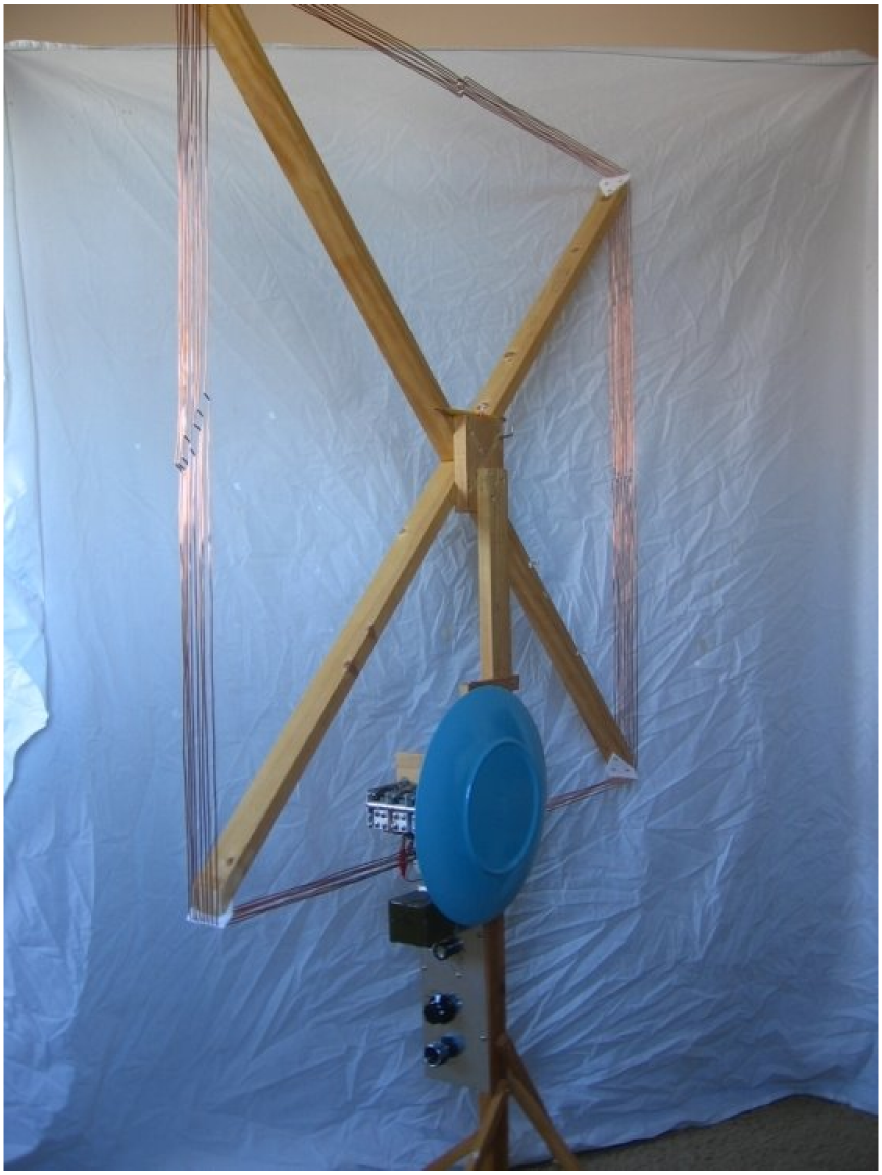
My set is a simple double tuned with a Tuggle front end and home brew friction reduction drives. A high/low switch spreads out the band a little further. The "high voltage insulators" are wood toy wheels stacked up and painted white. I thought it would add to the industrial look of the set.

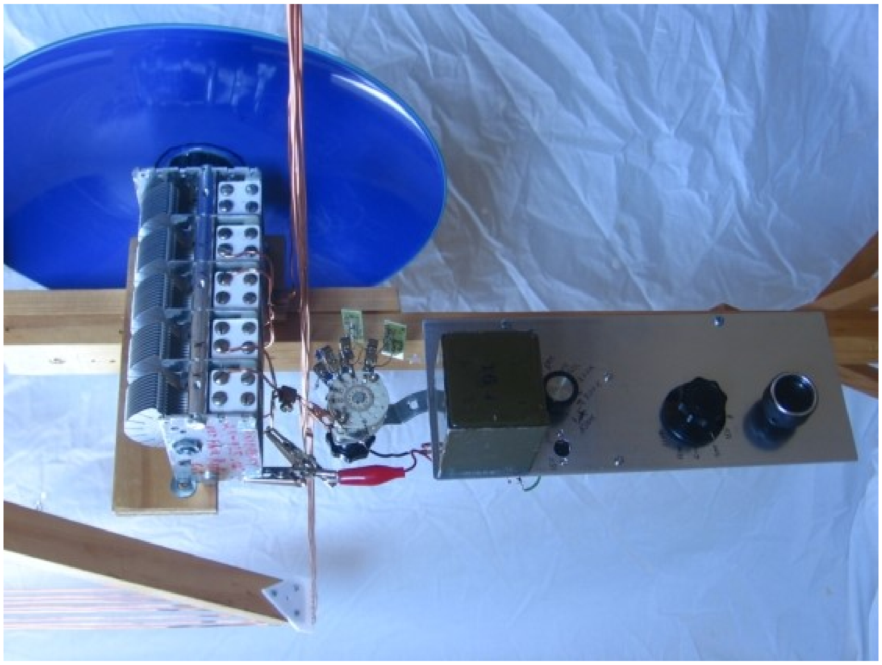
My antenna is a 300' longwire, 30' in the air and oriented NS. The ground is tied to the cattle fencing (welded wire on metal post every 10') that runs all over this part of the county.

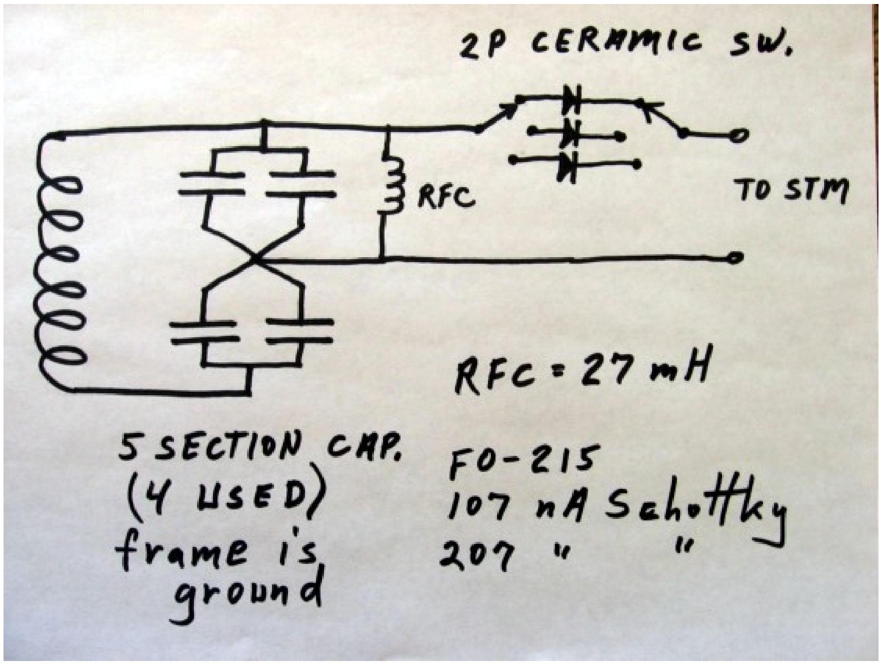
The unit is sitting atop my universal match box. The headset is SP units mounted in old Olympus stereo headphones.

The barely visible blue pin is my location on the map.

Garry Nichols, Loop Class Entry







This is the same set used in the 2008 contest, except for a few minor changes:

-I took off the Select-To-Match this year and ran the loop with only the T3/AM-20 transformer (100:100k) and a 107 nA Schottky diode.

-Big can mic elements in series had a 2 uf electrolytic between them and the transformer.

This setup (with short leads) got rid of my FM interference completely, and I did not hear the intermittent hum that I was picking up last year from various orientations of the loop.

Kevin Norton, Open Class and Short Wave Class Entries

Sets: On B'cast I used the K-3 xtalset. It is a 75 ft longwire through a wiperless ceramic 4 gang, then to a 4 ceramic gang wiperless tank (660/46 ferrite assisted air coil). Each var cap is wired so that a 500 gang is bussed to the adjacent 500 gang. So two 500 gangs equal one leg of my cap. The gnd is to the FRAME of the tank var cap (NOT the "cold" stators).

The det tank uses the same coil type and var cap type / wiring layout. There is no det tank connection to Earth or ant tank.

All caps are 6:1 ball driven and have oversized insulated wooden knobs.

A single FO 215 was used fully at the hot end of the det tank. Although single Schottkys HAVE been used in past contests, results were worse this time (for whatever reasons).

The match is 2x UTC A-27s and the phones are David Clark SP types wired in series @1200ohms.

Future K-3 improvements could include raising the match Z by wiring in additional A-27's, changing the benny pot to a higher value and trying various benny caps. Also a set of high band coils should wake things up quite a bit on the high end.

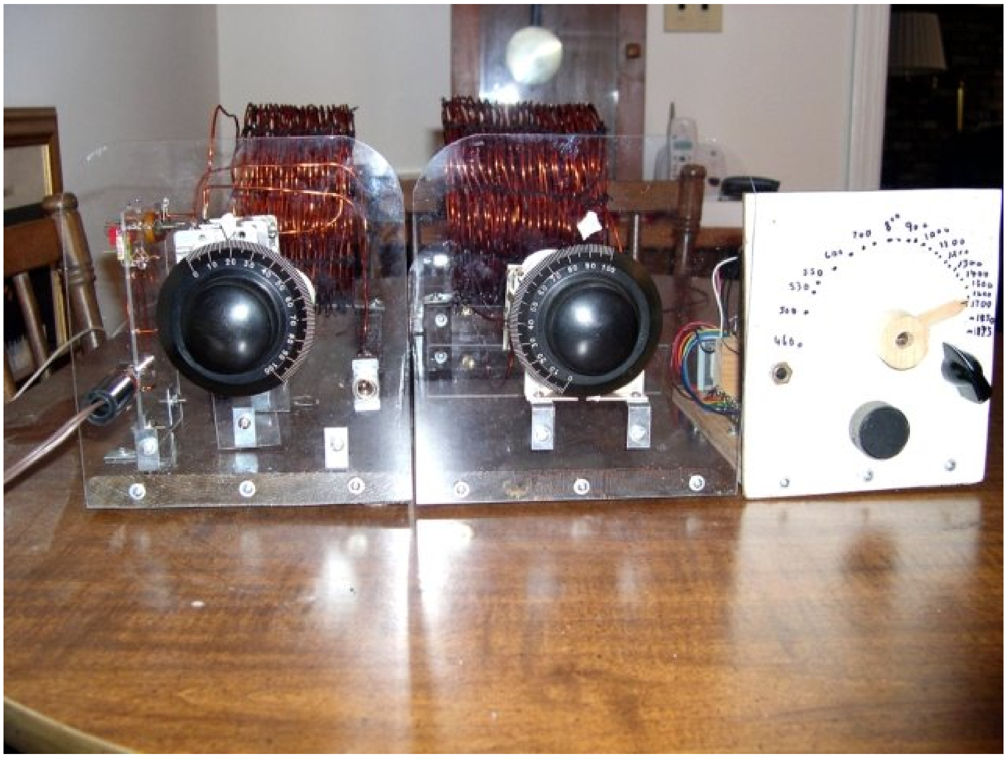
An outboard applied RF bias is available by a weak signal digital B'cast transmitter and coupled to the set by an unterminated litz air coil. This transmitter only covers 600 Kc and up, so an analog Heath signal generator fills in from 530 to 600. Using just a tiny level of (variable) RF greatly narrows the bandwidth. Strong locals are obliterated and signals otherwise NEVER copied come into good audibility. There is an almost "regenny" sound when doing this.

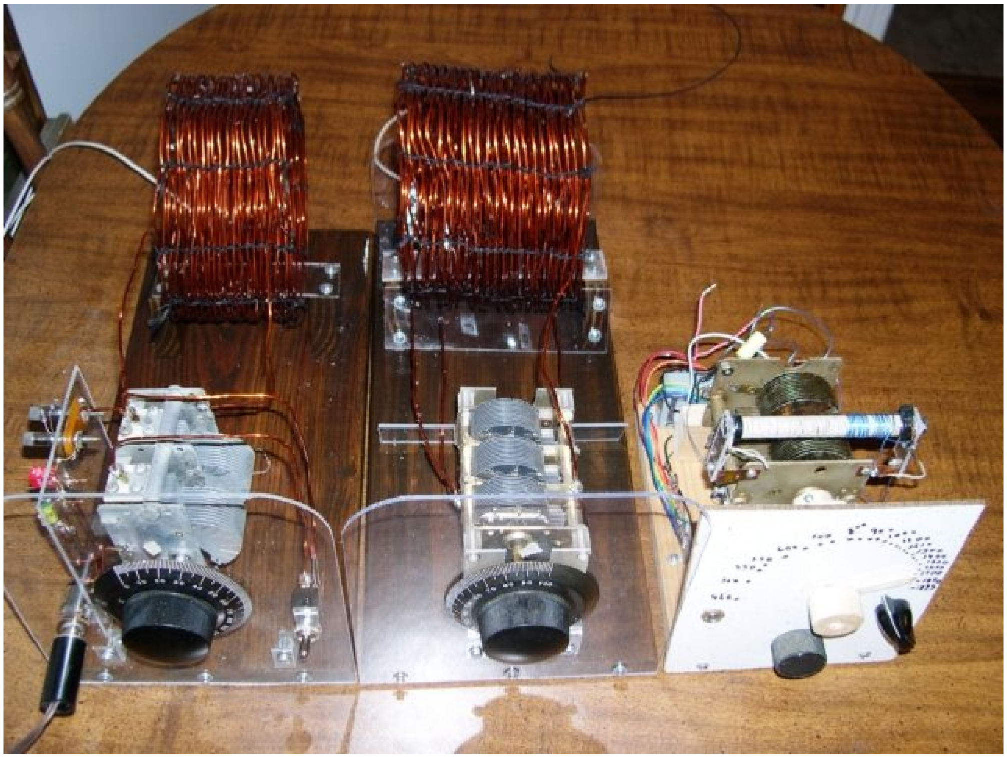
I can find stations by using the analog or digital scales, bias the set into the "supercharged" mode,and then peak all controls. Then I simply shut down the RF, move the bias coil away and wait for a signal to come up into true xtalset passive copy.

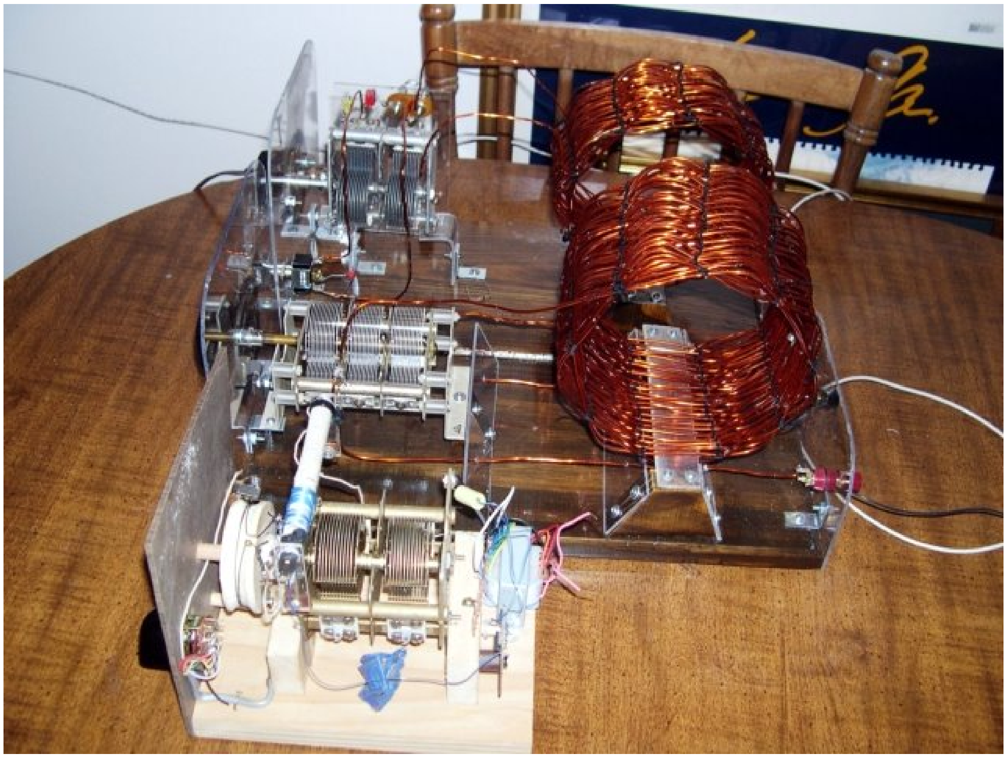
The HF set was a simple affair. A wiperless ceramic var cap on 11uH homemade > air dux. There is a two turn ant coil . The tank has no gnd . The det is an unknown diode directly into series xtal earphones.

Overall a good a time, despite a slow start.

Curtis Gamble, Open Class Entry







This is my first passive receiver that was not a bread board set. It includes a Tuggle antenna turning unit with 12 gauge enamel wire rook coil, center of the picture, a 1N34 detector with 14 gauge enamel wire rook coil, and a Triad SP 21 300 Hz to 100Kz response output to sound powered head phones.

The unit to the right is an IC detector with an ALD110900A and BOGEN T725 trans- former to the same sound power headphones. The 160 meter flat top dipole is up about 45 feet, plus I use a 50 foot long wire, and a house copper water pipe ground.

I have two locations I can work, my old home place in Tuscaloosa, Alabama in the same shack I've had for over 50 years, and the home I live in now in Hoover, AL. I worked this contest in Hoover, Alabama. This location has very low noise, and after sunset the local blow torches are not a issue. I normally don't use a trap.

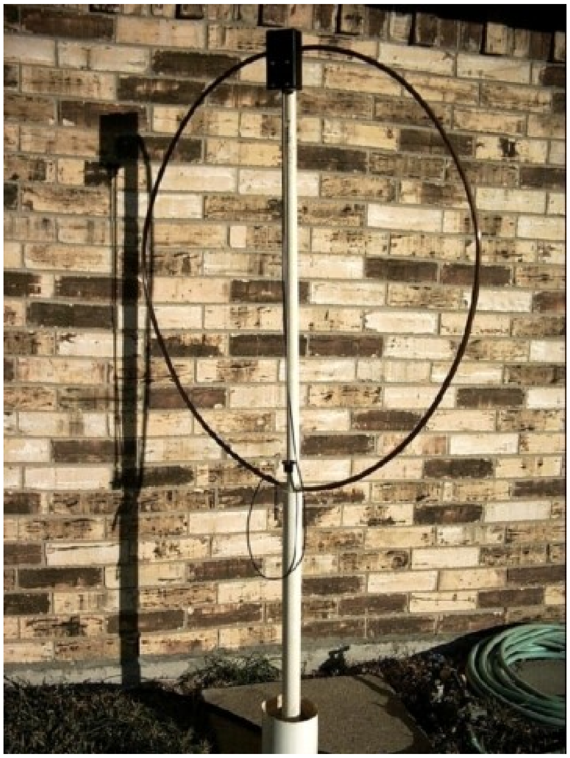
This is the same radio I used in the ’07 contest, with no additional modifications. I call it the Llama, because of the case it’s built in.

The antenna this year was a 40 foot inverted L, about 25 feet above ground. I added two additional ground rods to my ground system this year to compensate for the smaller antenna. I had to make extensive use of the wave traps this time around, the locals at 1080, 820, 770 were totally dominating the middle of the band.



This is a very simple SW loop antenna radio I converted from a QRP 40 meter small transmitting loop I built about 5 years ago, and has been beaten up quite a bit over the years. It consists of a four foot diameter, ½ inch copper loop that is paralleled with a 365 pf air variable capacitor and a 1n34a diode detector.

I hooked it to my copy of Steve Bringhurst’s ultimatch unit for impedance matching and listened in with a pair of philmore xtal earplugs in connected with a radio shack mono y-adaptor.

In the (broadcast band/mw) contest, I used my latest receiver which was just finished right in time. The schematic features a double-tuned circuit with an additionally antenna matching cap and probably does not show surprises. The whole device was designed to gain highest Q values within my possibilities. I used polystyrene coilformers of the german manufacturer Reinhöfer which already offers the possibility to gain high Q values.

The coils have 185µH and were wound with 460 x 0.02mm litz wires. Measurements of such a coil show increasing Q with frequency up to 1550kHz and a maximum value of app. 830. A noteworthy improvement was reached by drilling six holes in each segment of the coilformer, now the Q increased across the frequency range of interest (in Europe, station in the mediumwave band cover a range from 531kHz to 1611kHz). Moreover, also a maximum Q of app. 1020 was found. Therefore I decided not to use contra-coils since I wanted to avoid the use of any (more or less lossy) switch in the RF section.

To preserve the high Q, I used TRW silver-plated air variables in the antenna and detector circuit. Coupling of the coils is made variable by a somewhat old-fashioned technique as used in old tube radios. Anyway, it is working very smoothly and reliable.

Housing is done by low-loss polypropylene sheets which keeps the Q up (refer the measurements of Dick Kleijer at http://www.crystal-radio.eu). In difference to most constructions presented so far, I completely enclosed the device. The main reason is to keep dust away from the caps - if you ever did Q measurements of high-quality aircaps with dust in between the plates, you will understand why. The dust probably kills more Q than the housing might do, providing the use of appropriate materials (thus, no wood, PVC, metal, acryl glas or most colored plastics).

All variable caps are completed by 6:1 vernier dials made by UK Jackson Brothers. 5082-2835 schottky diodes are used as detector diodes and provide the best matching between detector circuit and audio transformer I was able to realize. The matching transformer with an input impedance of 500k was also manufactured by Reinhöfer. The radio is completed by a pair of balanced-armature headphones Baldwin Type C as well as the usual benny circuit.

The real backdraw of my receiver is the limited antenna. I live in a five-storied house which not much chances for long antenna wires. Thus my best option was a 10m wire between my balcony and the roof of the next garage. Compared to my other set which I used in the last sprint contest and still used for the longwave and shortwave band in this year, selectivity and also sensitivity was noteworthy improved. The 6:1 vernier dials are already a minimum requirement, 12:1 or more would be favourable.

In all, I was surprized about how many and how distant stations I was able to receive during the contest.

Shown below is the set used in this contest for SW and LW. It is the same set used in the 2008 Sprint Contest.

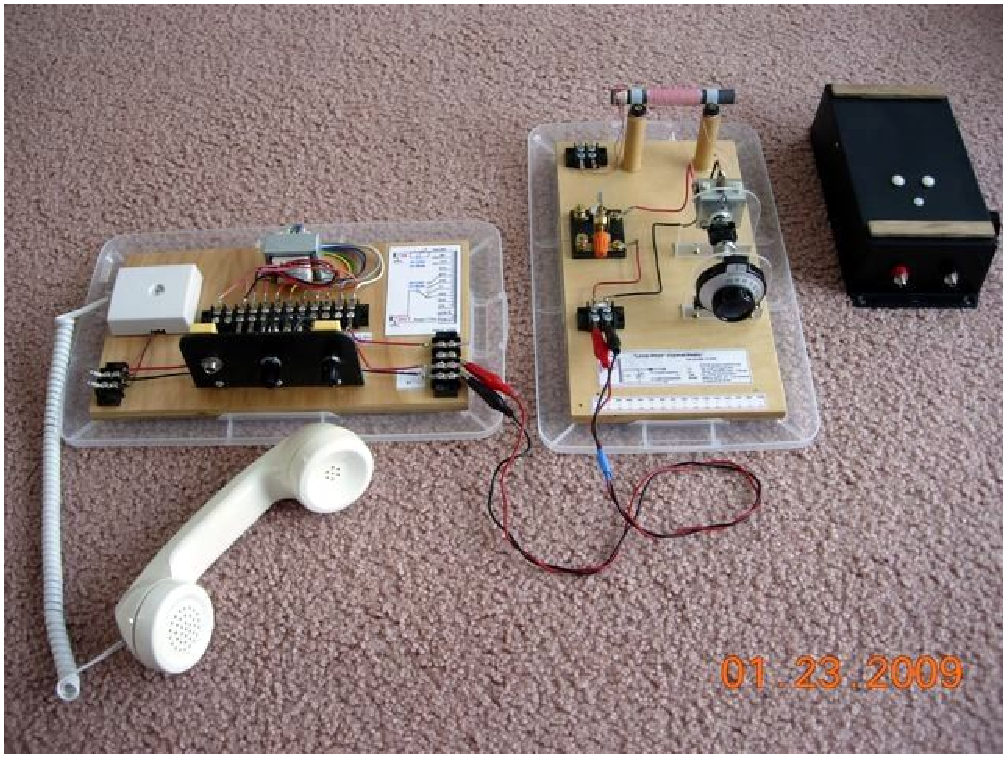
Dan McGillis, Open Class Entry

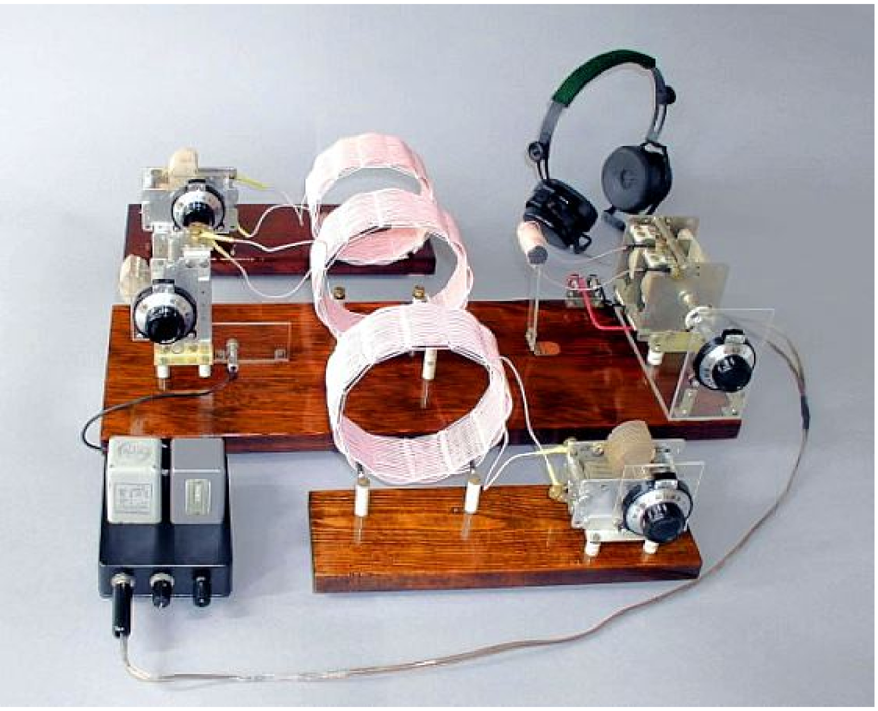


My entry this year is a simple loop-stick crystal set - something the grandkids can play with. It's been described at the RadioBoard.

I used a little antenna tuner that's also been described before. Click here for the RadioBoard link for the tuner.

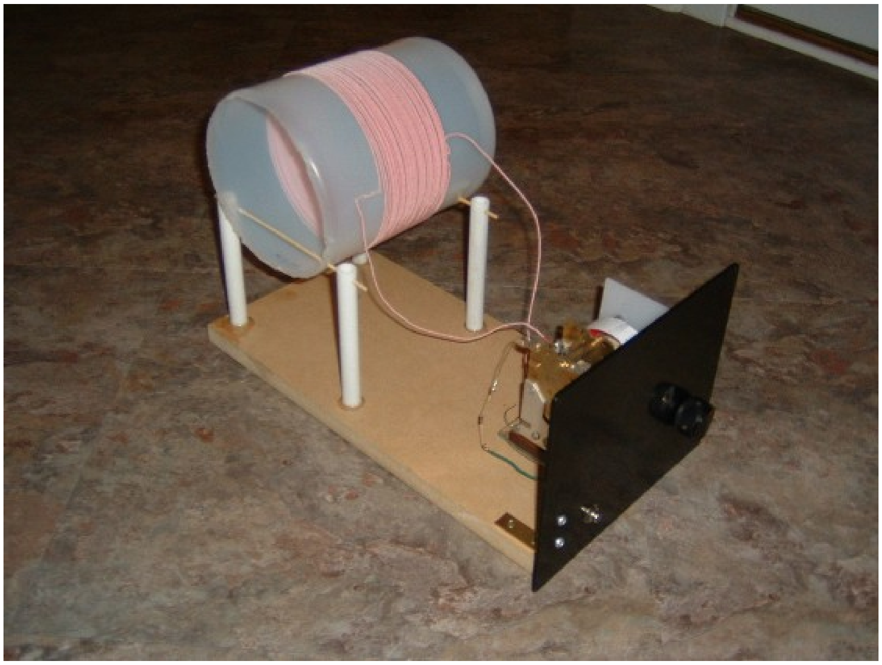
The set didn't do too bad for only a few days of listening. A big 200' antenna certainly helps :-) It makes a nice progressive set. I started out using Mike Peebles's cat's whisker detector stand It's very smooth & works well. Substituting a FO-215 diode perked things up. Adding a Bogen+Benny for some audio matching made a big difference. Coupling-in a simple antenna tuner really brings-in the DX and kills the SW ghosts.

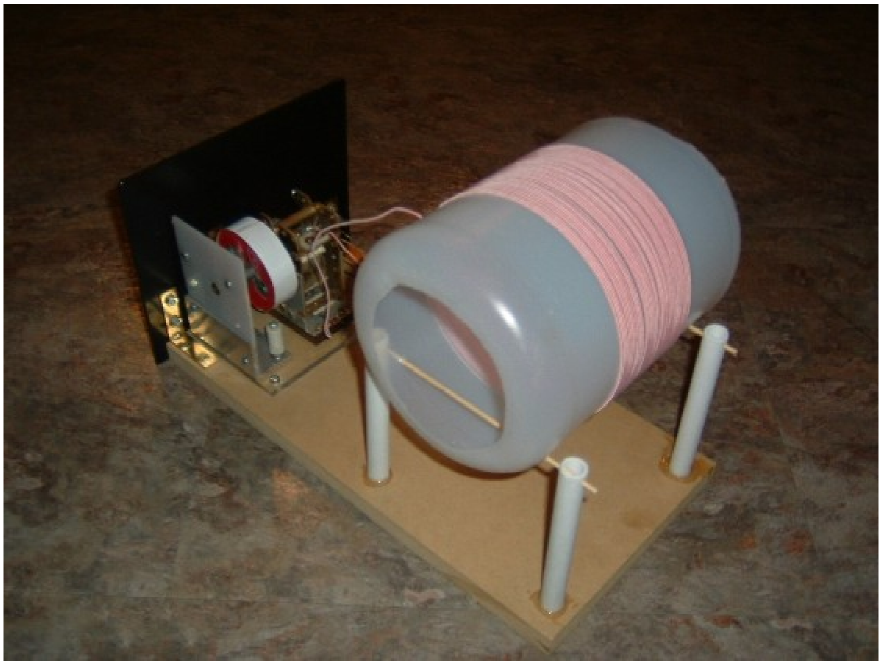
Mike Tuggle, Lyonodyne-17, Open Class Entry



This year's effort was something of a disaster. The night before the start, our annual Kona winds blew the antenna into the mango tree and ripped it to shreds. I spent opening day out in wind and rain, in true ham fashion, getting the antenna down and re-erecting a simple longwire in its place. Conditions throughout the contest were blah. I don't know whether the original 4-wire flat-top was really that much better, or if conditions were simply that blah.

Jack Bryant, Open Class, Two-Way Shortwave Class, and Below BCB Class Entries





I only worked the first 24 hours of the contest on the broadcast band. I had copied one navigational beacon at 529 kHz, and decided to build a simple set for LF. I copied four more stations for a total of five. The stations are: DIW, CLB, BH, YYW, and LYQ.

I worked a few contacts on 75m AM using the xtal set as a receiver. My transmitter VFO had bitten the dust, but I got a crystal for the transmitter on Saturday, and that worked fine.

I used essentially the same set for the broad cast band that I used in years past, with minor mods to the antenna tuner. I did use Schottky diodes for the fist time. I used two in parallel during the day, but moved to just one at night due to the overload I experienced using the pair.

This year I used a different set of phones made from SP mic elements. The earphones were made of hard plastic, but the headset band placed the phones on the back part of my ears. I did not experience the ear pain of previous years, but I made sure to move my glasses far up on my head, or not use them at all to eliminate pinching the nerve beside my ear.

I have used a Realistic DX-398 for several previous contests, and I used it for this one, too. I used a PC for logging along with paper copy backup. I used a four foot table from Lowe's as my listening post.

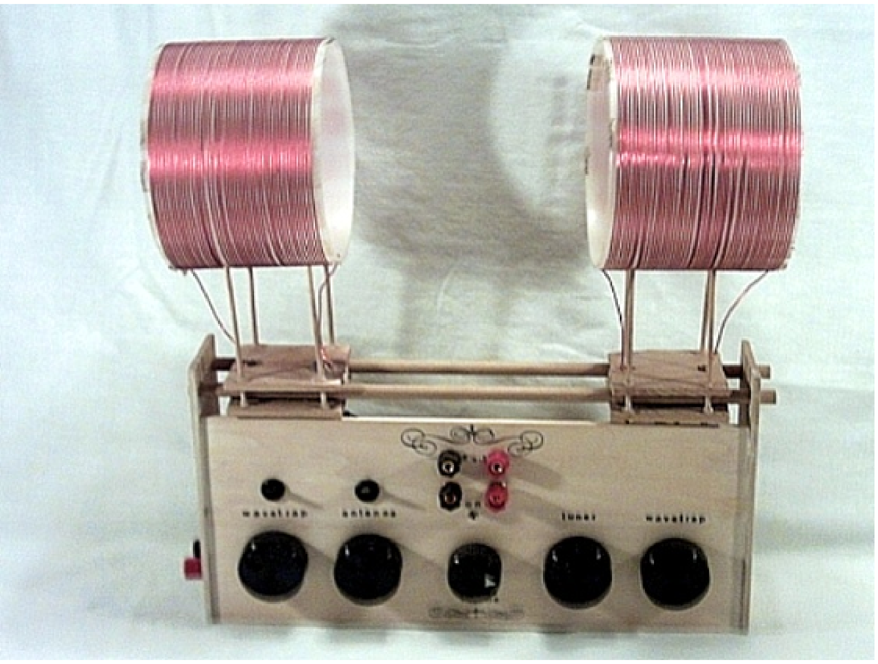
Crystal Radios Of The 2005 Contest Entrants

Page 1

Charles Pullen (Chuckster)



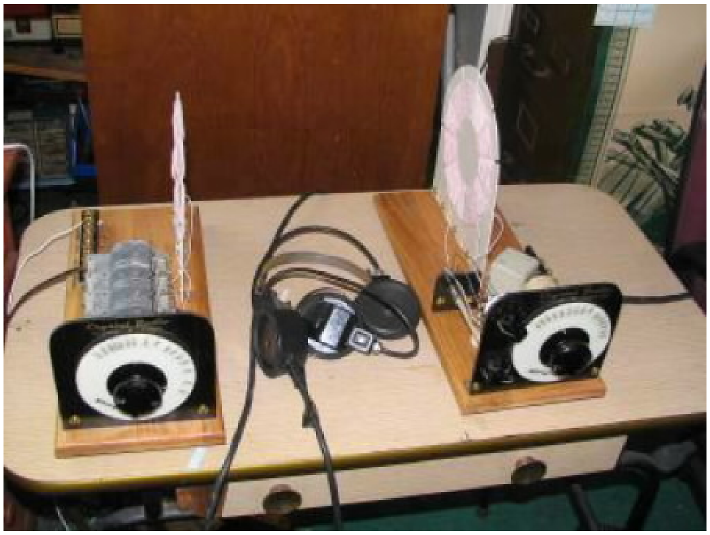
Basic Double Tuned Set

The antenna coil is a 5.5 inch space wound with 16awg @ 240uh paralleled with a 20-340pf air variable, loosely coupled to a 5.5 inch space wound with 16awg @ 270uh paralleled with a 20-340pf air variable detector coil. The detector used was two 1ss98 schottky diodes in parallel. I Used the original ultimatch circuit by Steve Bringhurst for impedance matching. Used two Philmore xtal earbuds in parallel, connected to the ultimatch with a radio shack mono Y-adaptor.

The lone wave trap is a 4" x 3/8 inch ferrite rod wrapped with litz to obtain 270uH with a parallel 20-340pf air variable. This was arranged so it could be loosely coupled to the detector coil, suspended inside the center of the detector coil or outside the detector coil in axis with its center, or rotated 180 degrees out of the way. I found this particular style of wave trap to be extremely effective for even the strongest local.

The antenna was two separate wires, one 50 foot wire tacked to the ceiling running about 30 feet east-west the remaining twenty feet running north & south. The second antenna wire was a portable reel of 25 feet borrowed from my Grundig YB and attached to the set. This is in a second story apt. Ground was about 25 feet of speaker wire running to a CWP.

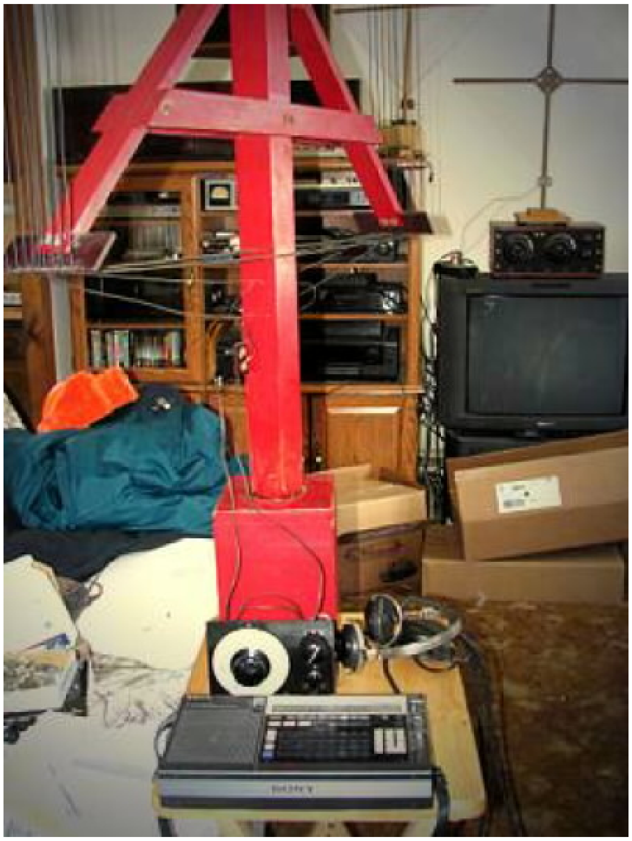
Dave Schmarder



See complete description of Dave's radio at this link: Dave's #50 Set

Open Class

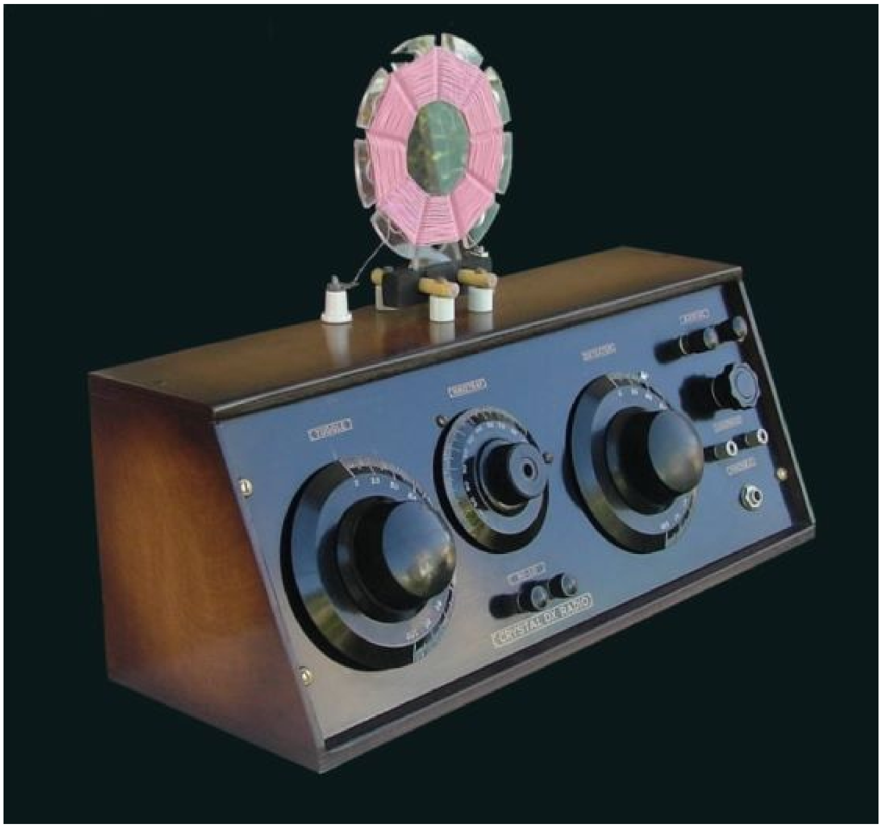
Dual 660/46 litz coils and two tuning capacitors.
differential coupling capacitor
Schottky Diode Detector
Sound powered headphones
Antenna 40 meter wire up 3 - 4 meters running east to west.



33 inches (84 cm) per side. FO-215 Detector, Bogen transformer, Sound powered phones

See the details of this loop at Dave's Loops Page.

Bill Meacham (Exray)



This set is my third generation of a model based on Steve Bringhurst's TK-2 toroidial set. I went with an external detector coil on this one which offers the advantage of being able to close-couple an external trap (not shown) to the detector coil to notch out instances of interference when the coil itself is picking up local signals via the air.

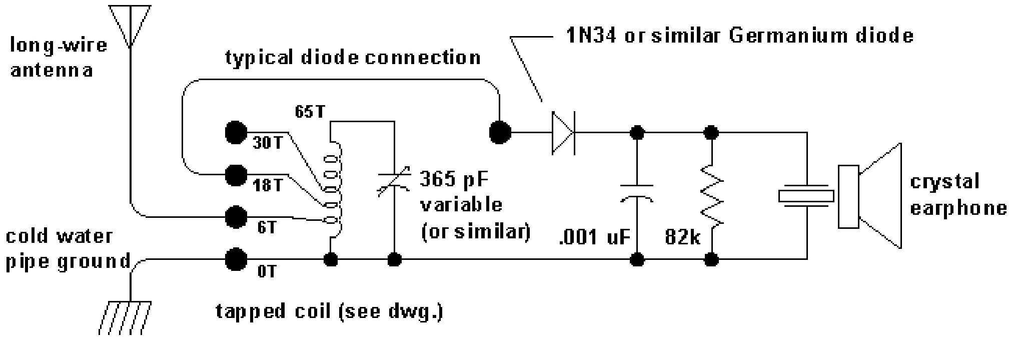
The set is built on a Garolite front panel with custom-made decals and lacquered for durability and shine. All of the RF components are on standoffs to avoid any possible leakage path through the panel. Vintage tuning capacitors were used and they have been thoroughly cleaned and checked for rf integrity. Both are straightline tuning types to minimize crowding at the high end of the band.. The input tuner is of the "Tuggle" type and uses a toroidial inductor. The inline wavetrap also uses a toroid. The detector uses a nice Pilot Kilograd tuning cap and a coil of 165-strand litz wound on a Lexan former. Its Q is greater than 500 across most of the band. Detector is a germanium FO-215 and the set uses a Calrad output transformer with an adjustable AF impedance matching control (benny) for minimizing distortion on strong local stations. I have been using the set with sound powered phones and they match well.

Calibration on this set is very accurate and it's easily resettable to locate particular stations. I added a set of front panel terminal posts to allow for tinkering with other detector tank options. The coil mounting assembly on top is also configured in this fashion to allow experimentation with other coils. Ceramic standoffs and feedthru bushings were incorporated to assure minimal losses.

Cabinet is homemade, made with Baltic Birch and is stained and lacquered using clear and toned lacquer.

Ed Phelps

.. is the same 140 ft, base insulated, vertical I used last year. (picture is crooked, not the tower)

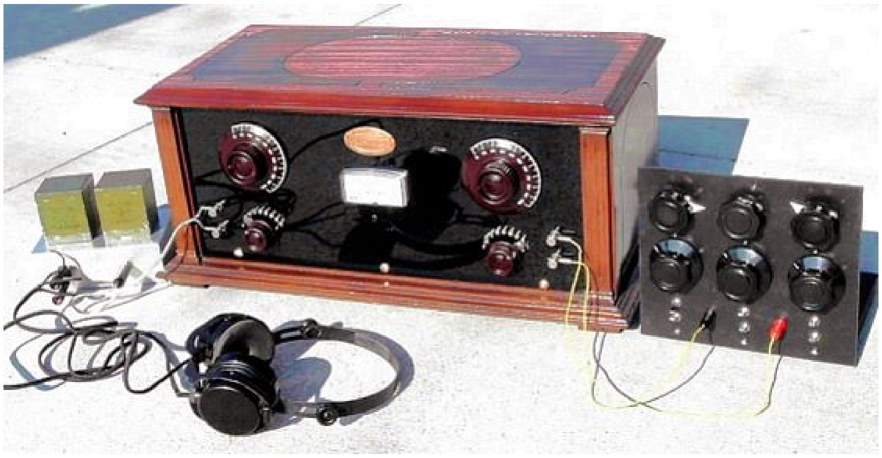


long-wire antenna
typical diode connection
1N34 or similar Germanium diode
65T
30T
18T
6T
0T
365 pF variable (or similar)
.001 uF
82k
crystal earphone
cold water pipe ground
tapped coil (see dwg.)

Crystal radio with typical connections for a long wire antenna and good ground connections. The diode is connected for weak signals and moderate selectivity.

I made a few minor changes to this circuit. In place of the 1000 pf capacitor, I use 250 pf. The 82k resistor, I changed to 100k. I use a pair of ceramic earphones, wired in series.

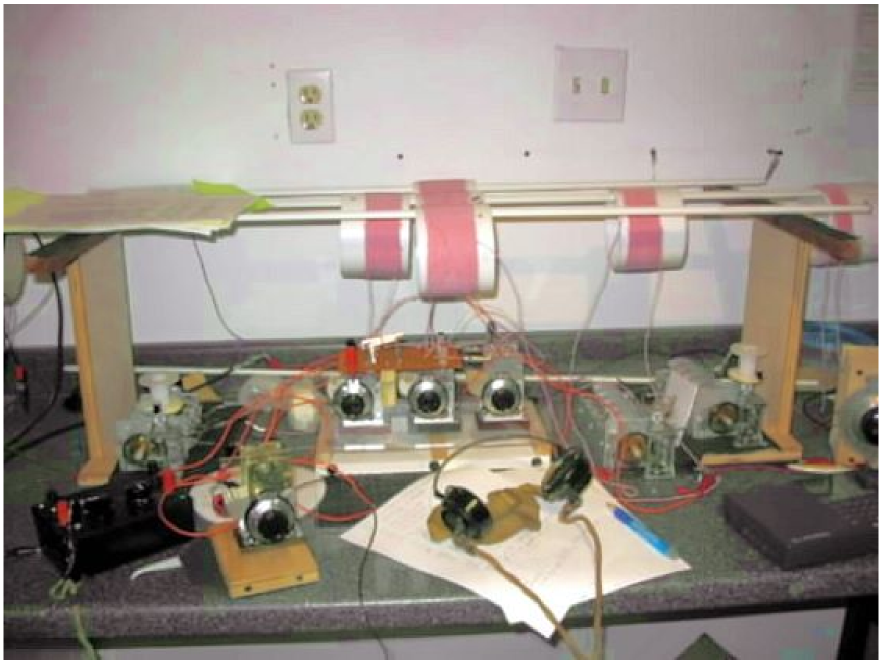
Eric Haydon



The contest this year was a lot of fun. I put in many many hours of listening. The band was very up and down in Nebraska. Thursday and Friday nights were the only nights that I would call "normal". The unusual conditions on the other nights did however allow for the reception of a few stations that I had never heard before on my crystal radio. I probably heard at least 30 more Spanish speaking stations than I logged. I only logged the ones that were very strong or heard almost every night.

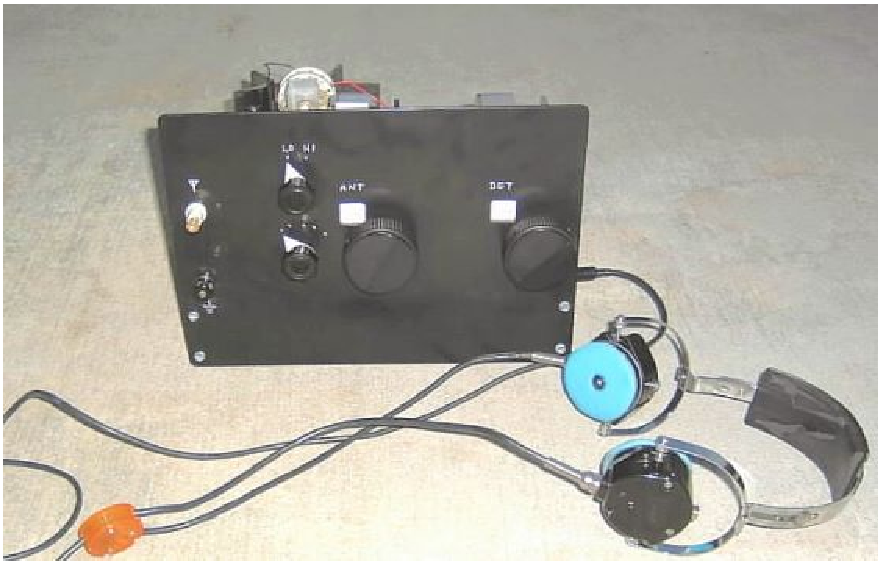
I heard many more stations this year than last year due to several improvements that I have made to my listening station. I used the same crystal radio as last year with the following improvements. My antenna is now higher and has been extended to about 240 feet in length. My ground system is improved. I was lucky enough last summer to acquire a pair of RCA "big can" headphones in very nice condition. They do help some. I finally built some filters that work very well to trap strong local stations. This allows me to now receive quite a few new stations on frequencies close to my local stations. The last improvement > is that every year I get "smarter".

Gil Stacy



Set: Same set as last year.
Headset: RCA Big Cans tuned and recharged by Steve Bringhurst.
Antennas: 88’ top loaded vertical up 50’ and 180’ inverted “U” up 50’.
Ground is the post 2004 DX contest ground described at the bottom of
this page

Jack Bryant



I used the 2004 BCB Contest set again this year. We moved after the last contest, so the antennas, ground system, and location were different.

I used two antennas. There first was a top loaded vertical. The top section is about 110' long and is a 80M - 10M trap dipole. The antenna is up about 50' high. The coax feed line is used as the feeder.

The second antenna is an upside down U, roughly 40' vertical on each end, 260' horizontal. I feed it with ladderline in the horizontal section, about 20' from where one end goes vertical. This makes it about 60' from one end of the wire. The antenna was used in three different configurations:

1) Each bottom vertical run is grounded. This is the grounded loop configuration.

2) Only the end closest to the feedline is grounded. This is similar to an inverted L approach

3) No ends are grounded. This is similar to an off-center fed dipole. All changes were done manually (no switches or relays yet).

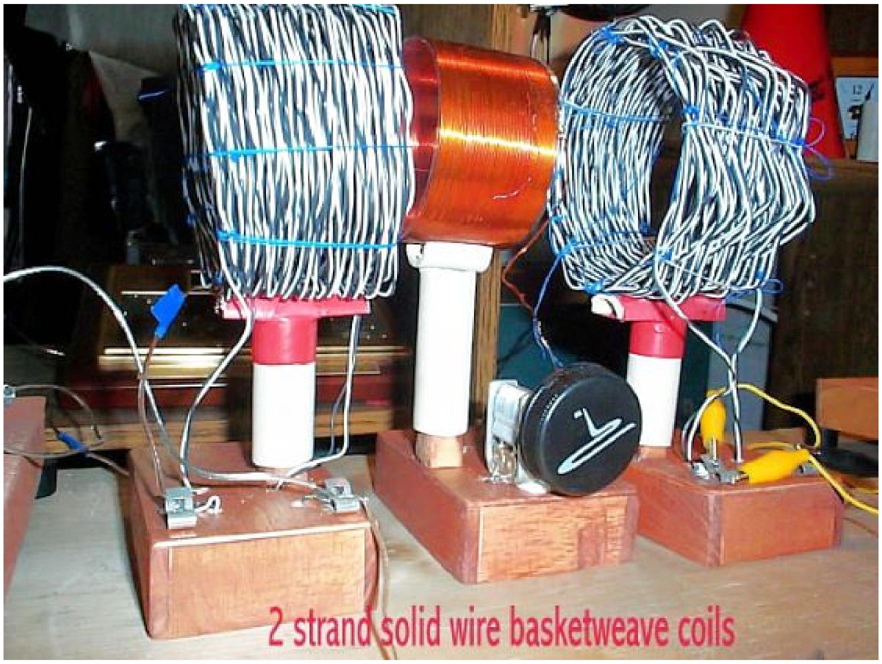
Crystal Radios Of The 2004 Contest Entrants

Page 1

Lou Dayich



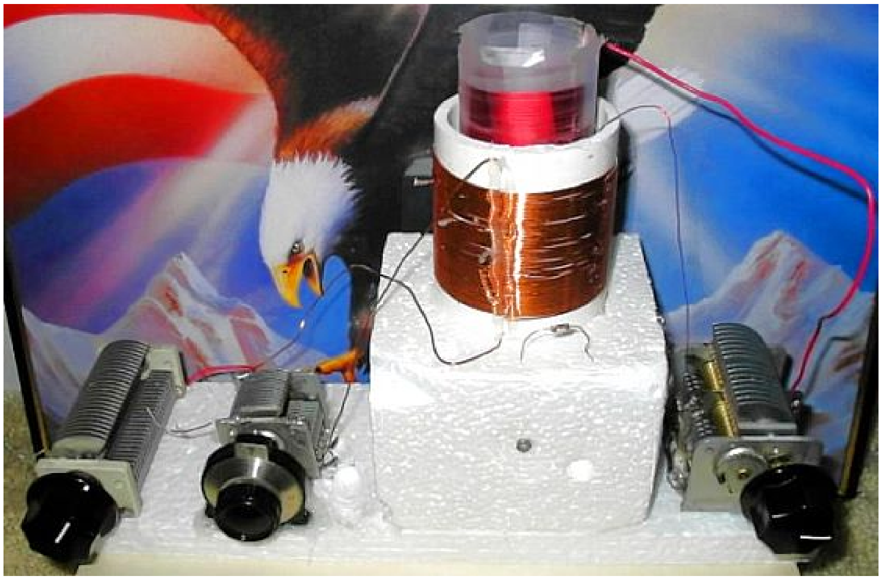
I have attached a photo of the set that I used during the contest. Daryll Boyd posted a picture on his site. I humorously called it "The Bondini". The most interesting feature is that this uses 4 inch basket weave coils with 9 points- double tuned.

The wire is 2 solid strands of twisted wire. I use a schotty diode and sp phones with a Bogen matching transformer. I wired it in as many combinations of coil and cap as time would permit.

Bob Jewell

Here is Bob's DX set.

Alex Perez



Hobby Class Single Tuned Crystal Radio Capable Of DX My antenna consists of 70 feet of 18 gauge plastic insulated tinned copper wire oriented in a North East and South West direction with the lead in pointing North East. The far end is elevated over 40 feet while the other is only 12 feet high. A cold water pipe ground connects to the receiver via 15 feet of insulated 14 gauge solid copper wire.

A 250pF ceramic frame air variable capacitor couples the antenna to the receiver. The tank circuit is composed of a 365pF phenolic insulated air variable capacitor and a coil of 60 turns of 21 gauge wire wound on a 2¾ inch PVC form. It is tapped at 30, 40, and 50 turns from the ground end.

To combat the QRM generated by WXEM, only a mile away, the wave trap has to be closely coupled to the tank circuit. The trap is composed of a 250pF phenolic insulated air variable capacitor in parallel with a 60 turn coil of 26 gauge wire on a one inch diameter form.

Best sensitivity and selectivity is obtained with the 30 turn tap. Usually a single Philmore crystal earphone and a selected germanium diode were employed. Some improvement was noticed when using two earphones in series, probably a better impedance match.

I attribute my success with such basic equipment to mostly quiet RF environment, many hours spent DXing, and listening well into the night and the morning on one occasion. Furthermore, I was fortunate to acquire some high scoring stations. Somehow I heard two different stations on 630 25 minutes apart. WAVU was only 203 kilometers away but running a mere 28 Watts! Still, this does not compare to KEYH on 850. It was 1,211 kilometers away and transmitting at a power of just 185 Watts! The remaining acquisitions were locals, 50 KW Clear Channel, or not too distant 5 and 1 KW stations. I received one Canadian and one Cuban station, both 50 KW. The furthest catch was WBZ, Boston. A station on 1260 identified itself as Radio Disney but I was unable to obtain a call sign. Out of three possible candidates, I am fairly sure it was WWMK. Using a spotter set to ascertain direction,the station was either from Chicago or Cleveland, certainly not Boston. 5,000 Watt DX from 800 kilometers away is certainly not uncommon for me, but anything else would be. Besides, I did log a few stations running 5,000 Watts from Ohio.

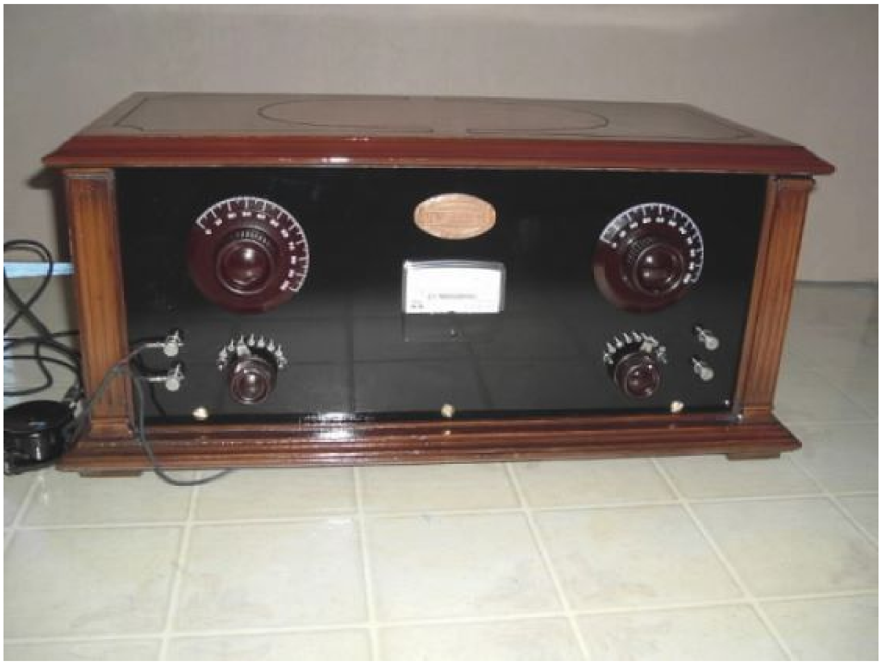
Evan Haydon



My crystal radio is a design that has evolved after many years of searching for a good design. Most of the ideas used in this radio came from internet sites. No litz wire here. Just old cotton covered 20 gauge wire wound in a basket weave form. No sound powered headphones here. Just my trusty old magnetic Trimm Dependable's.

Yes, the meter is in the circuit all the time. It is a 50 µA movement in series with the headphones. It is helpful in maximizing design of the circuits, selecting the best crystal to use, and in tuning taps and caps for maximum signal reception. It indicates carrier strength of the received signal. The carrier contributes nothing to the audio heard in the headphones. A signal of 1ua is 100% readable. One local station gives a reading of about 500 ua.

My antenna is 18 gauge solid magnet wire. It is basically a Windom antenna that is insulated at the supports which are at the ends and at the lead-in point. It is 180 feet long and runs due east and west. The wire to the receiver comes off at a point about 60 feet from the west end and is about 55 feet long. The lead-in take off point is up 36 feet with the ends up about 24 feet.

The radio is made in a 20's battery radio wood cabinet. It uses three Atwater Kent variable capacitors. It uses Atwater Kent knobs with two sets of antique switch points mounted on a black plastic front panel. Genuine Atwater Kent copper emblem at the center top of the front panel. Antique connectors are on the front panel for antenna and headphone connections. Wiring inside is all by 16 gauge bus bar. 1N34A diode. The primary and secondary coils are 4 1/2 inches apart with no electrical connection between them. I have not found a trap circuit that helps enough to talk about.

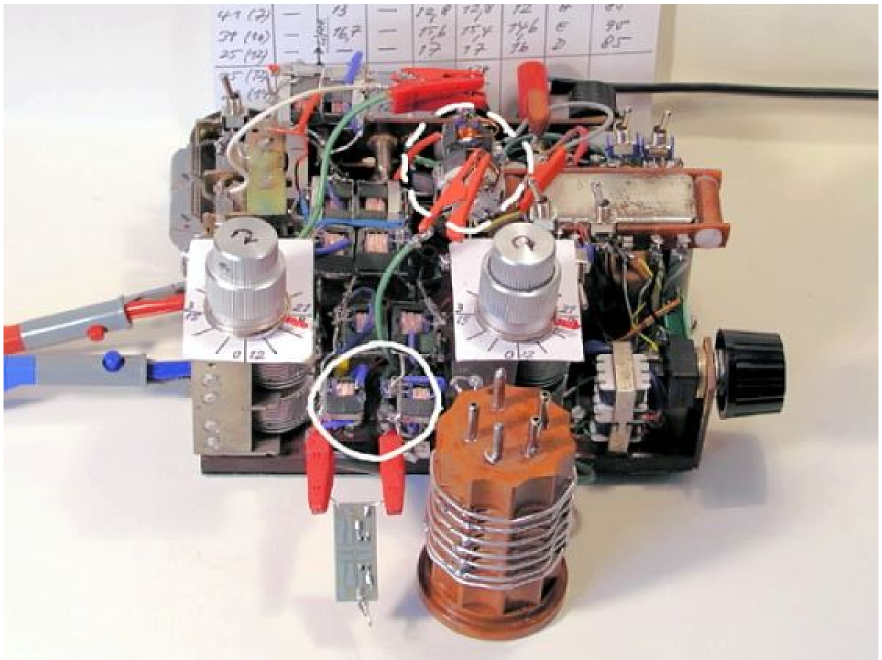
Berthold Bosch



2004 XSS DX Contest Information (SW, Open Class)

My 2004 contest log containing 156 SW stations (incl. 5 of uncertain ID) suggests that conditions in Central Europe are still more different from those in the USA than on the MW band. There are a lot of high-power SW/BC stations of 100 to 1000 kW in the numerous European countries and the neighbour areas, and particular networks that operate on rather many frequencies - like R.Free Europe, R. Liberty, VoAmerica (partly R.Sawa), VoRussia, etc. with their various programs. It is mostly possible to ID the received stations of these networks, but often difficult to determine the site (country) from which the particular tx operates. Only a few real DX stations are in my log with China/Peking being the most distant one (9500 km). So, is it really fair to compare my results with those obtained e.g. in the US if one gets one point,also for every "nearby" SW station?

I used my 2003 contest set (see Wuggy´s 2003 Contest site) which I extended for SW reception. This consisted in installing an air coil of 4 uH (fore in photo) for the 13m and 16m bands, a pair of Epcos pot cores of SW material K1 with solid-wire coils of 5.5 uH for 19m to 25m (marked by broken circle), and pot cores with 45/46 Litz coils of 10 uH for the 31m to 75m bands (full circle). Except for the air-coil tank I generally employ double tuning. The principal circuit layout for SW is the same as in the 2003 set (Ben Tongue approach). With the 5 SW coils there are now in total 13 coils in the set (LW, 3*MW, 3*SW), not counting those provided for triple tuning on extra boards (Boschodyne Plus).

At SW frequencies the obtainable tank resonance resistances are much lower than those at MW. Consequently sensitivity is a serious problem, and more often than on MW one hears two or even three stations at the same time. For improving the situation I employed a modified MFJ tuner 901B in front of the set (not shown in photo) to squeeze the last dB of power out of the antenna and trade it for selectivity. The tuner can be wired to act as a SPC or SL pre-selector, an "ultimate transmatch", or a capacitively-coupled third tank circuit (for triple tuning). With triple tuning I measured for example at 41m a loaded (i.e. with A/G and phones connected) -3dB bandwidth of 23 kHz and a -10dB b.w. of 47 kHz. -- I use a Schottky diode BAT 62 (as in photo) if high sensitivity is the prime goal, and 2 or 3 paralleled 5082-2835 if it is selectivity. The outdoor loop that I described last year in my contest report served as antenna.

For finding and then logging stations I employed two methods:

(1) First I scanned the band with my spotter radio ATS-404. When the scan had come to stop at a station, I tuned the xtal set to the particular frequency with the help of a loosely-coupled signal generator. After turning off the signal generator I then listened if I could hear that station in the SP phones of my set.

(2) When I had the xtal set tuned-up to a particular frequency within the SW band investigated, I slowly moved the sig. generator about 50 to 70 kHz around this frequency while watching for beat notes. When I found a strong beat I tuned the set to zero this beat, then turned off the signal generator, and listened whether I could hear the particular station. This was done repeatedly to scan various parts of the band. If I had been able to definitely hear the station in methods (a) or (b) I partly switched-on the spotter radio again for helping to identify the station received on the xtal set.

During this concentrated listening on SW, I found the rule of thumb again confirmed that Mike Tuggle formulated in a recent paper: "If you can hear them on a radio, you can hear them on a crystal set" - nearly always in my case.

2004 DX CONTEST SET DESCRIPTION

This is basically a Lyonodyne with some differences, such as:

1. The complete set has been built on one chassis and all controls are at the front panel.

2. The C1-C2 coupling is double: by means of rotation and changing the distance, and wave-trap is coupled only by rotation.

3. Using one or both sections of the C2 spreads the upper BCB.

4. There is one built-in detector diode with the possibility to experiment with other types of detectors.

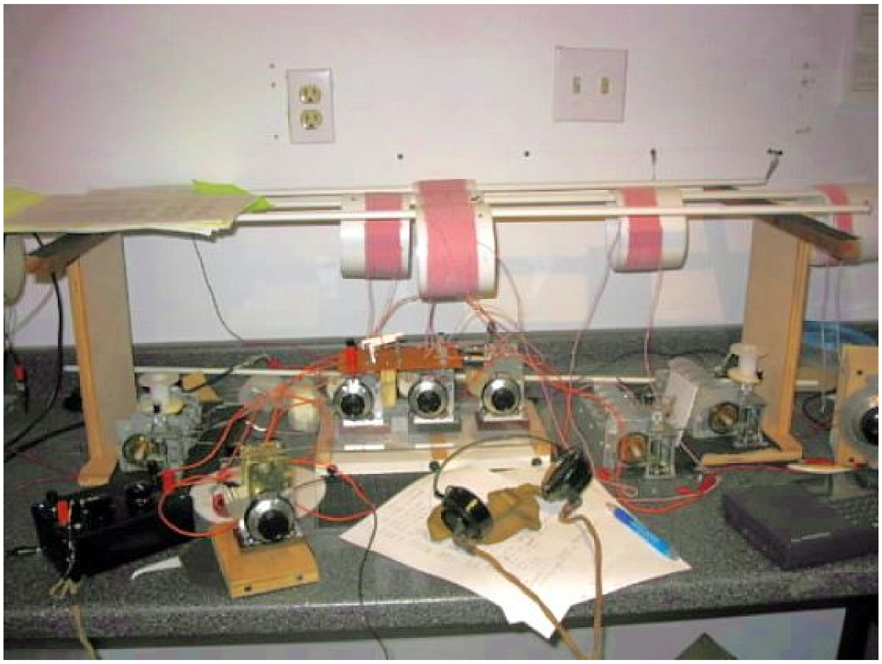
5. Audio transformer is home-made and together with the impedance-selection switch allows the use of different impedance headphones, as well as a sensitive speaker.

I am aware of all the imperfections which are subject to experimental improvements. I want to thank Mike Tuggle who invited me to join the Contest and gave me many useful advice. My gratitude also goes to Ben Tongue for helping me to improve my impedance-matching transformer.

N.B.: The switch s1 is not shown on the photo (introduced after the photo was taken!).

antenna position

Gil Stacy



Five Litz 4.5” O.D. coils are in use at all times. The detector and antenna coils are controlled by the three 8-1 vernier dials mounted in plexiglass. The antenna circuit is a modified Tuggle front end approach with one TRW cap (C1) in series with the antenna with C1’s stator linked to C2’s stator. C2 is tied to the antenna coil and earth ground. C3 is tied to the detector tank. All caps are TRW’s previously available from Fair Radio. This offers the set more flexibility in tuning than its previous traditional Tuggle Front end which used a dual ganged cap.

The three inductive traps surrounding the detector tank are driven by one gang each of three five ganged traps with right angled 120-1 drives from Fair Radio. Hand capacitance is controlled by use of empty plastic wire spools, slotted to accept the dials of the right-angled drives. The stand-alone TRW cap with vernier dial controls the inline toroid trap. The three inductive traps are permanently set to trap locals 1400, 1290 and 1230. The inline trap is used trap two local stations at 630 and 900 when in their vicinities. Otherwise it is used to assist swatting down 1230. Untrapped, 1400, 1290, and 1230 will show up all over the band because of their proximity to my location. The phones are DLR5s matched to the set via an STM designed by Steve Bringhurst. The set uses 3 paralleled Agilent 5082-2835s and a 3RT 12101 which are selected via a switch. To the right of the set is my frequency spotter Radio Shack DX 398. The antenna is an end fed wire, approximately 140’ long, with a 90’ horizontal run, up 50 feet. A post-contest improvement by adding three 8’ copper-plated ground rods to existing water main ground has noticeably improved selectivity, sensitivity and my ability to control the qrm of locals 1230, 1290 and 1400. The new ground system has also opened up about 150 KHz previously lost to the above three locals.

Jack Ivey, BCB Class (crystal)

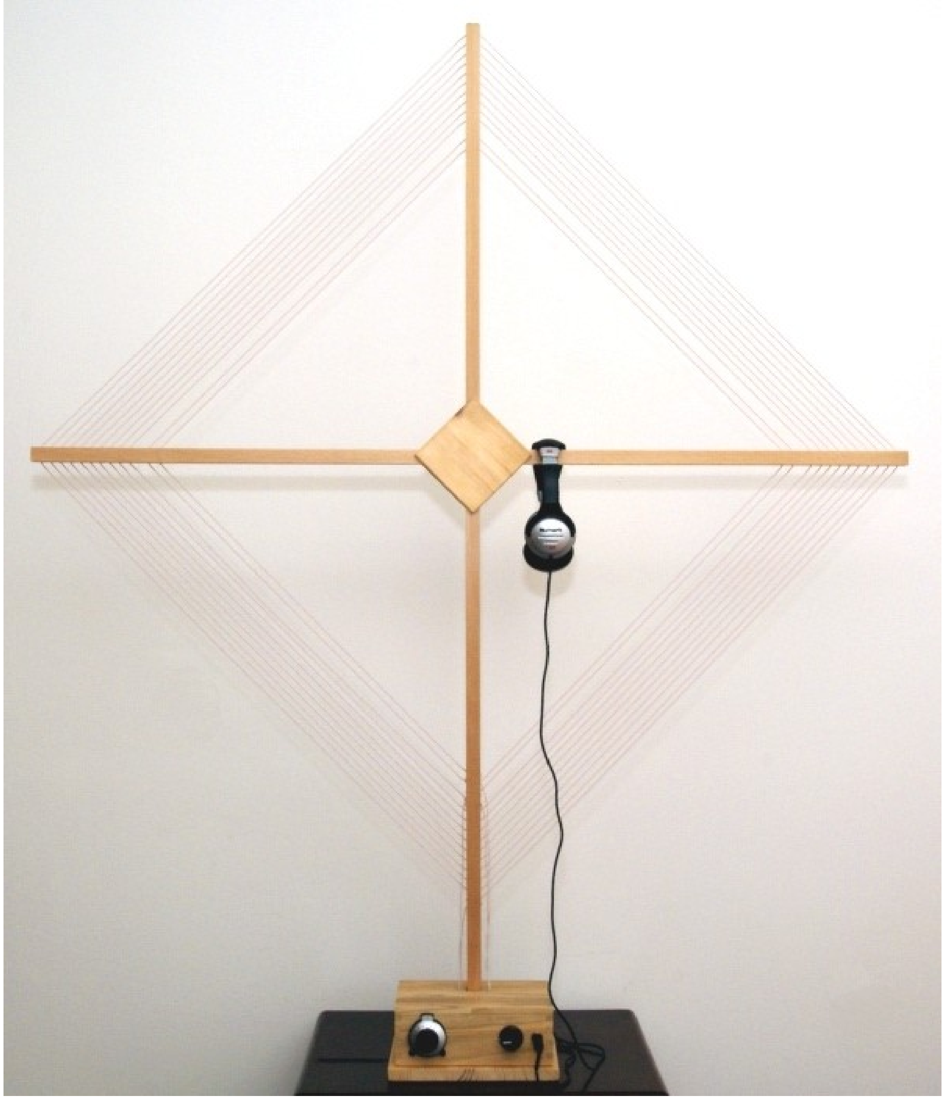
Equipment is a dual-tuned radio with spider coils of 175/46, Ge diode detector, Bogen matching transformer, modified balanced armature headphones, with a 250 foot C-shaped antenna about 8 feet above ground, #14 wire.

Kevin Norton, BCB Class (crystal)

Receiver was the "Crystal Commando". This set is a three coil Tuggle set w/cotton basket weaves. The det coil has ceramic var cap, all others are bakelite. Det. was FO215, w/ series crystal earphones. This set played VERY sharp at times . It can tune the upper part of the band in a wiper less configuration. Despite it's simple design I think the reason it worked so well was due to care in construction (i.e., component spacing and insulation). I wanted to take a step back from big litz and just see how well a simple set could be made to work.

Overall I quite happy with this set.

Ralf 'Brösel' Siemieniec, BCB Class (crystal)



For this years sprint contest I was curious about how my reworked loop antenna crystal radio performs. For this loop having a spiral loop design, I increased the size to 0.9m x 0.9m. Since the litz wire used before (150 x 0.04 mm) was not that much rugged, I switched to a double silk-covered 270 x 0.071 mm litz wire with an outside diameter of about 2mm. The air variable is a good quality three-ganged device with ceramic insulators, but just one gang is used. Tuning is done with help of a 9:1 vernier dial which is coupled by a plastic extension to the shaft of the variable cap. The air variable cap is isolated against the wooden box while the box itself is mounted head-down on a wooden base. The loop construction is also attached to the base although mounting all things together is a bit more difficult this way.

In difference to all loop antenna sets I know so far I decided to use one of the zero-voltage MOSFETs (ALD110900). The gate is directly connected to the hot end of the tank circuit; the only problem left was how to feed the source. There are basically two possibilities – connect the source via a capacitor or via a coupling coil. After making a simple spice model of the measured characteristics of the MOSFET and doing a number of Pspice simulations I found it is more advantageous to use a coupling coil. After finishing the radio I found that there were some annoying FM ghosts which are probably caught by the coupling loop. To get rid of these I added the FM choke. Matching to the headphones is done by a “Ueberformer” from Dave Schmarder. In the contest, I used a pair of sound powered phones with USIC elements from Dynalec (note that the photo shows my “self-made” phones with rocking armature elements made by Racal. The phones with USIC elements are a bit more sensitive, but the shown phones are very lightweight and comfortable).

The loop does perform very well and is surprisingly sensitive. Selectivity is quite good for a single-tuned unit, especially at the low end of the band. Tuning is rather sharp, therefore the vernier dial seems to be a “must have”. What I like most is the clean sound. I found no distortions so far even in case of strong signals.

Here is a Google map link that you might enjoy viewing.

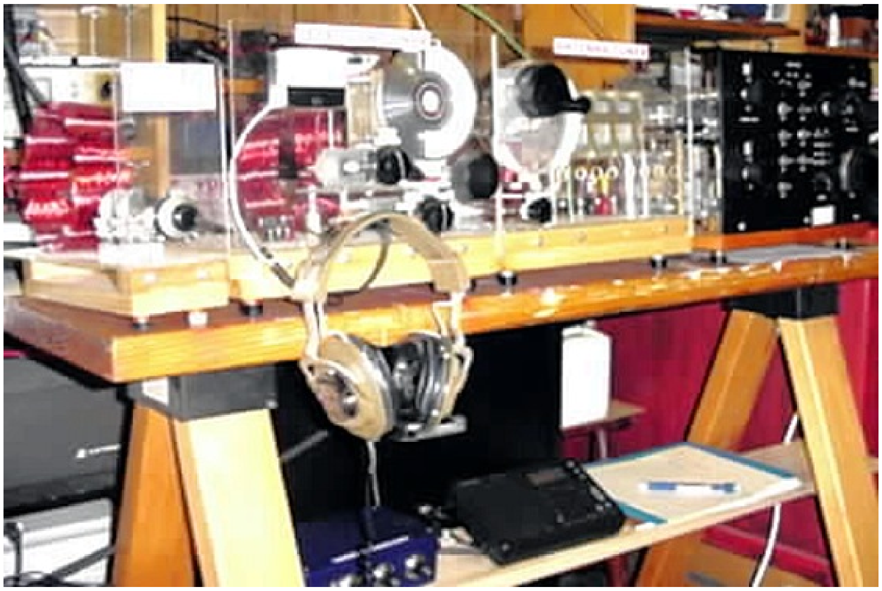
My crystal radio tunes the mediumwave (broadcast) band as well as the shortwave band, both are split into two subbands, and the longwave band. To keep the receiver small, I was using closed ferrite cores from Epcos, P18-11-M33 for the MW & LW bands and RM5-K1 for the SW bands. The coils are all done using litz wires 80 x 0.02 mm (two wires in parallel for MW and SW1) and two paralled litz wires of silver-plated copper strands for SW2. Actually, this is the same wire as I used for the wiring, the insulation of the silver-plated litz wire is made of Teflon, which should not cause too much losses (as I hope). The antenna and detector coils are each wound on a separate core which were later stacked together.

The radio has two tuned circuits and a variable antenna coupling and can be switched between single- and double-tuned mode. Additionally, there is an attenuator in case of need, the variable antenna coupling capacitor is a two-ganged type and can be switched in series or parallel. The antenna and detector tuning caps are both silver-plated devices. Rectification is done using two paralleled 5082-2835 for the BC band and again two paralleled BAT15-03W for the SW band. The matching section consists of two transformers - a 53.49 by Reinhöfer Röhrentechnik in Germany (input impedance 240k) switched together with a Bogen T-725. I managed to get a pair of Baldwin Type C headphones which are much more sensitive than all of my modern but more comfortable types.

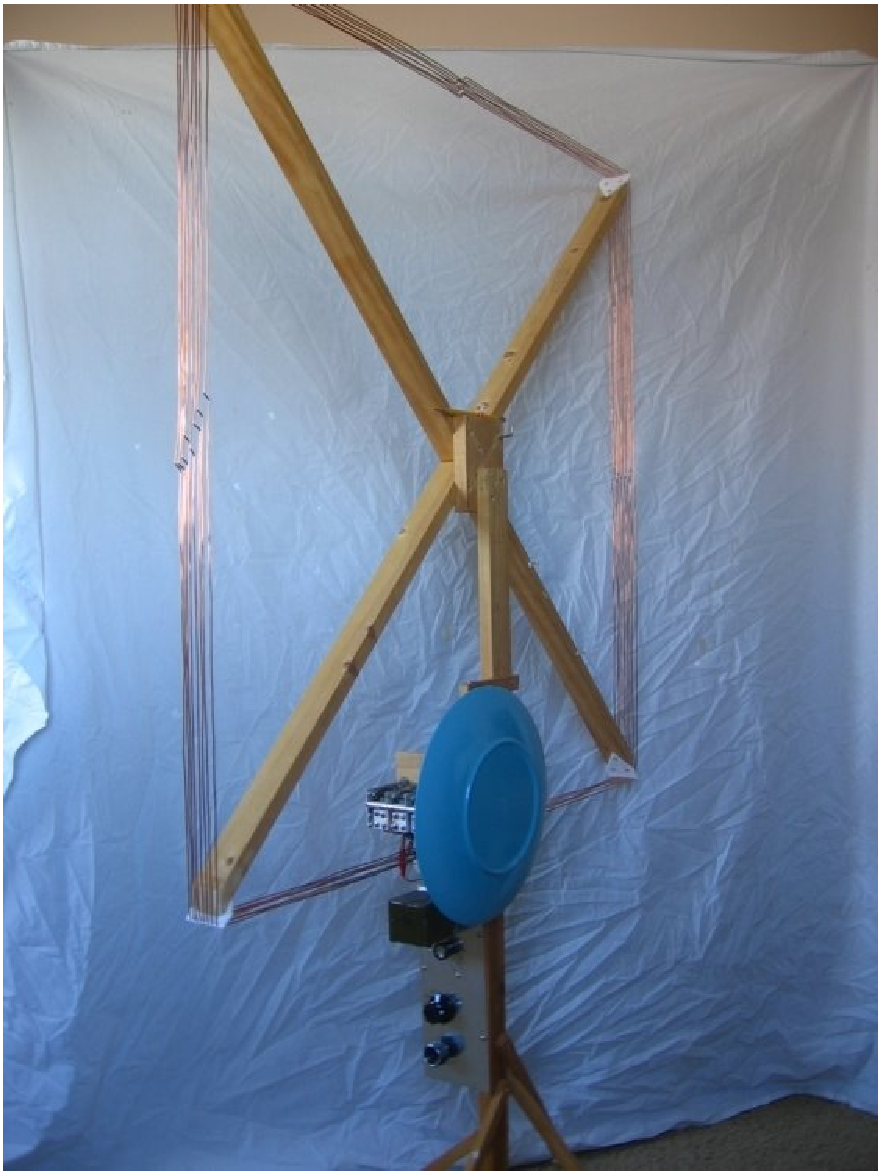
All is mounted at a polypropylene sheet for proper insulation. The most distant station received so far was 1419 km away in Tunesia. Could probably be more if I had another antenna than the metal made balustrade of my balcony - I live in a multi-party house, thus there is not much chance for long antenna wires.

Lem Morrison



Lem used an updated version of this set that was used in the last several Crystal Set DX and Sprint Contests.

Garry Nichols

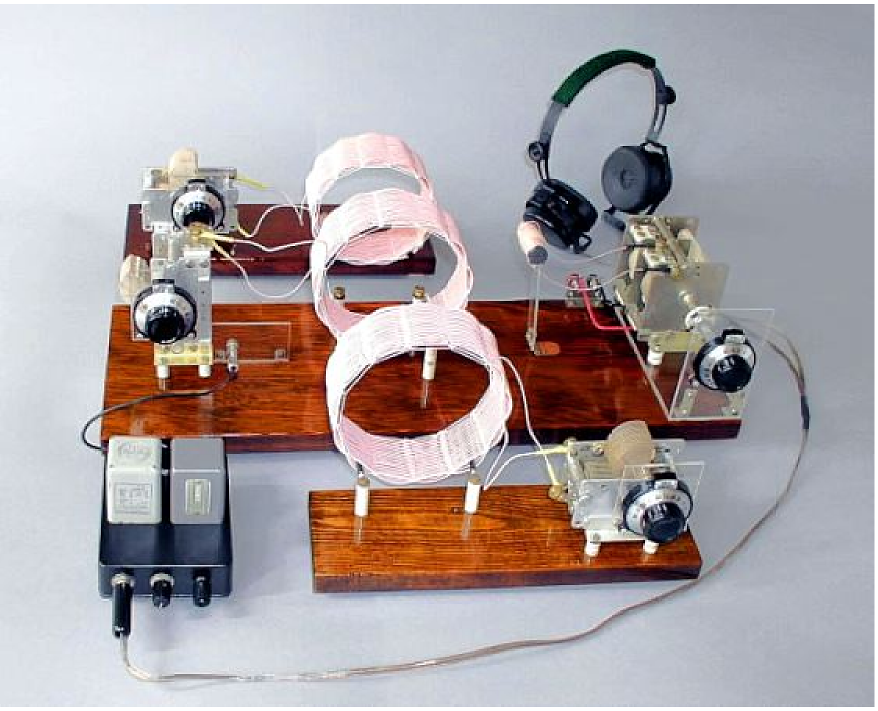


Same loop as in the photos for last winter's contest. However, I was not using the STM, only the T3/AM20 100:100k transformer and the single 107 nA Schottky. Also, I was not attaching the ground to the variable's frame and using a RFC for diode DC continuity through the variable.

The ground of the detector/audio went to the center of the loop winding > instead. I found that there was much less interference from a local FM station this way.

Click here to see more about this set that Garry also used in the January 2008 Crystal Set DX Contest.

Mike Tuggle



The infamous Lyonodyne-17, double-tuned, 12101 3RT detector, two wave traps, RCA Big Cans.

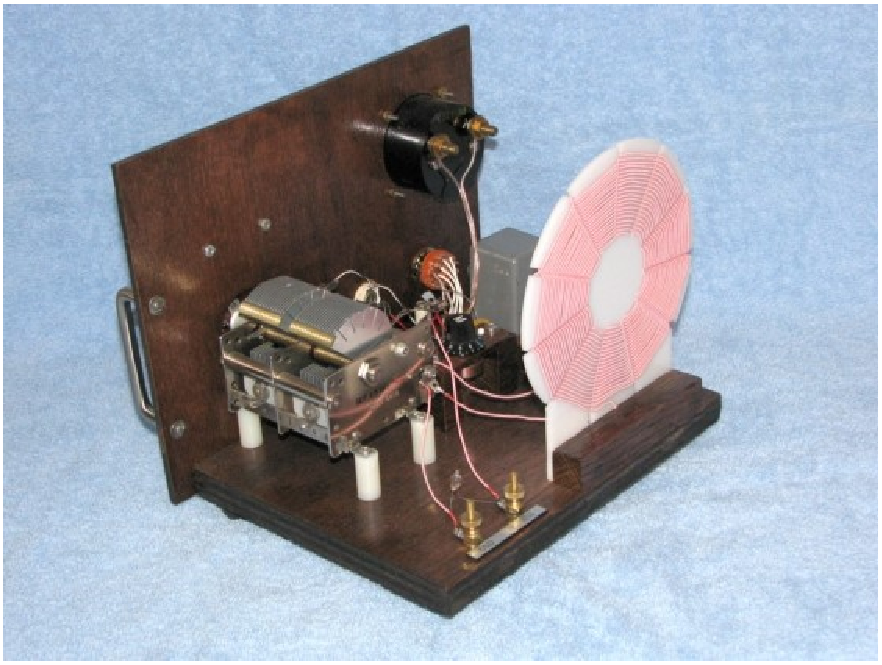
SIGNAL
CRYSTAL SET
TUNING
MATCHING
HEADPHONES
D. C. MICROAMPERES

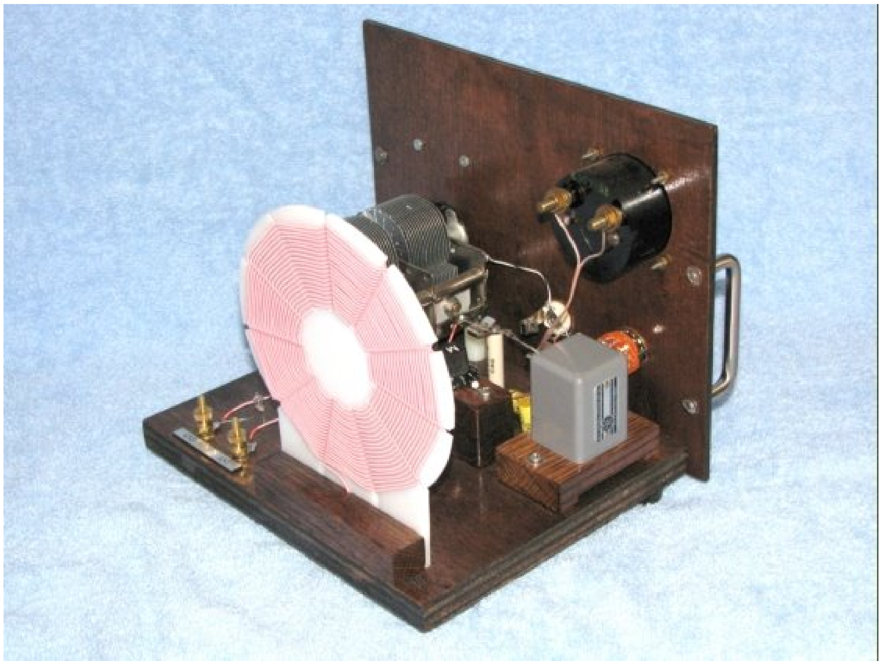
The set uses a Tuggle Tuner, a Schottly diode detector with three diodes in parallel, and a UTC A27 matching transformer.

My antenna was a 135 dipole fed in the center with 45 feet of 450 ohm open wire line. I connected the feed line wires together at the set and worked the antenna as a T against ground.

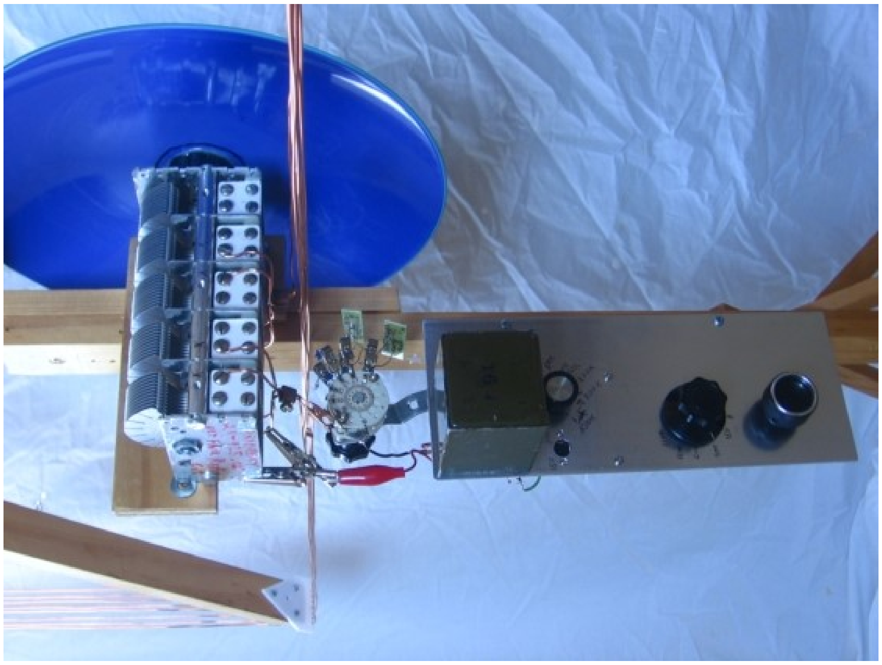
Again the contest was fun. I did better than last year, copying 100 stations. Conditions may have been better or it could be due to my new set and more sensitive headphones.

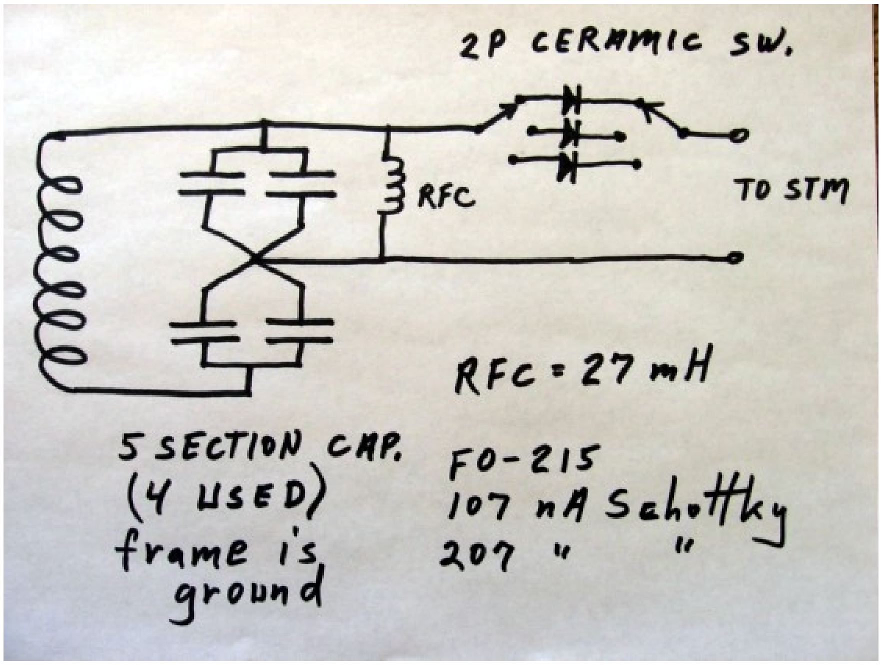
CRYSTAL SET



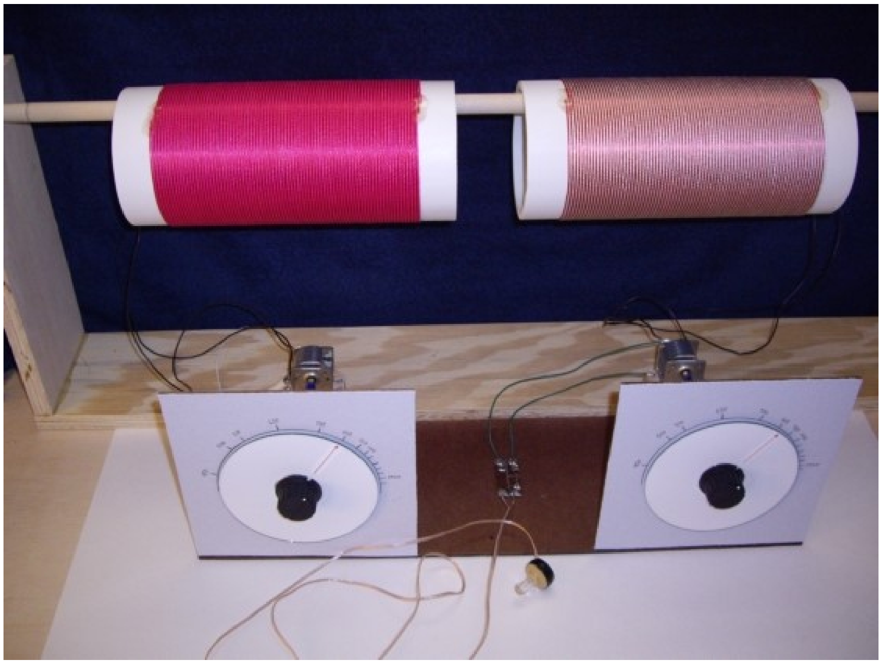


Garry Nichols





James Kretzschmar



This radio is big improvement over the radio that I entered in the 2001 Crystal Radio building contest. I started tinkering in early January 2008 and finally decided on a design on 17 January 2008, and built the radio that afternoon … ready to use the next day.

My coils are wound on 4.5” PVC pipe with 80 turns #18 wire space wound the width of the wire with nylon masonery cord. The coils actually have too much inductance, however I did not have time to change them. The variable capacitors have ¼” dowel wooden extensions to avoid the effect of hand capacitance. To provide smooth operation and stability a ¼” washer is glued to the front panel.

My antenna is about 200 feet of wire strung through the trees in the backyard about 20 feet up. In operation, the right side is tuned to where you want to be, then the left side is tuned for the strongest signal, the coils are moved in/out as needed for signal strength and selectivity. I have had real good results with this design.

At my location in Winston Salem, NC we have a real strong station at 830 KHz and I can routinely hear 840 KHz WHAS in Louisville, KY in the clear. Two small stations were heard during the 2008 contest: (1) WMAC 940 KHz in Macon, GA (2) CKNX 920 KHz in Wingham, Canada. A total of 35 stations were copied. A simple piezo earphone was used. I plan to tinker with this design to optimize reception.

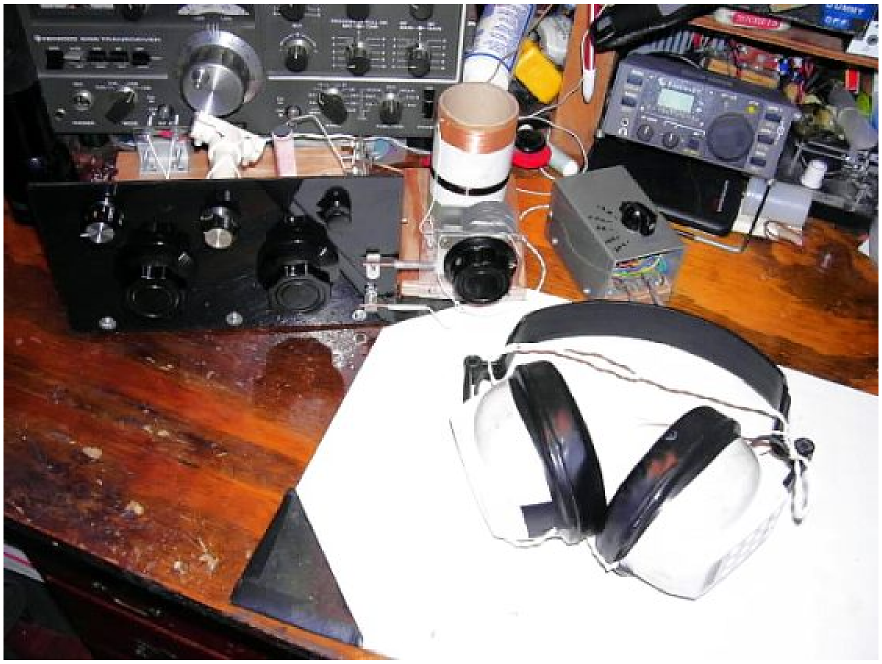
Crystal Radios Of The 2006 Contest Entrants

Page 2

Peter Kerttula

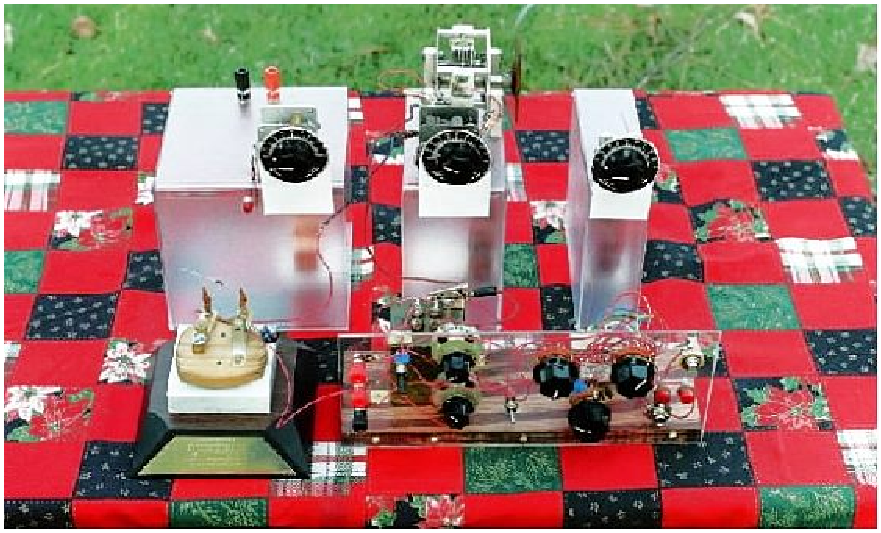


The rig for the 2006 contest is a Jim Frederick design, the Hobby Dyne 2. I added crystal switching and use a reduction on the tune side capacitor.

The headphones are sound powered made from SP mike elements. A bogen transformer handles the output transformation.

The antenna is a 100 foot wire bent to fit the lot! A cold water pipe handles the ground.

Mark Roliff



The unit at the left rear is the antenna tuner. The coil is 33 turns of #22 magnet wire. The cap. is a dual 365pf variable purchased from the XSS.

The unit at the center rear is the detector tank. Its coil is 40 turns of #24 magnet wire. The front cap. is a dual section variable salvaged from a junked radio. The smaller front section is not used. The rear cap. is used for band spread.

The unit at the right rear is the inductive trap. The coil is 40 turns of # 24 magnet wire. The cap. is a single gang 365pf purchased from the XSS.

At the right front is the detector stand mounted on a salvaged trophy plinth. The mass of the wood and marble lowers the detector stand's sensitivity to vibration. All logged stations were heard with the cat whisker and galena crystal. At the start of each listening session, I would tune in a weak local station using a germanium diode and then disconnect it and match the signal's strength and clarity to a hot spot on the galena crystal. The whole process took less than a minute. The crystal was purchased from the XSS.

The unit at the right front is my version of Steve Bringhurst's UltiMatch 2. I used a pair of RCA "Big Cans" connected to the Red tap of the Bogen transformer.

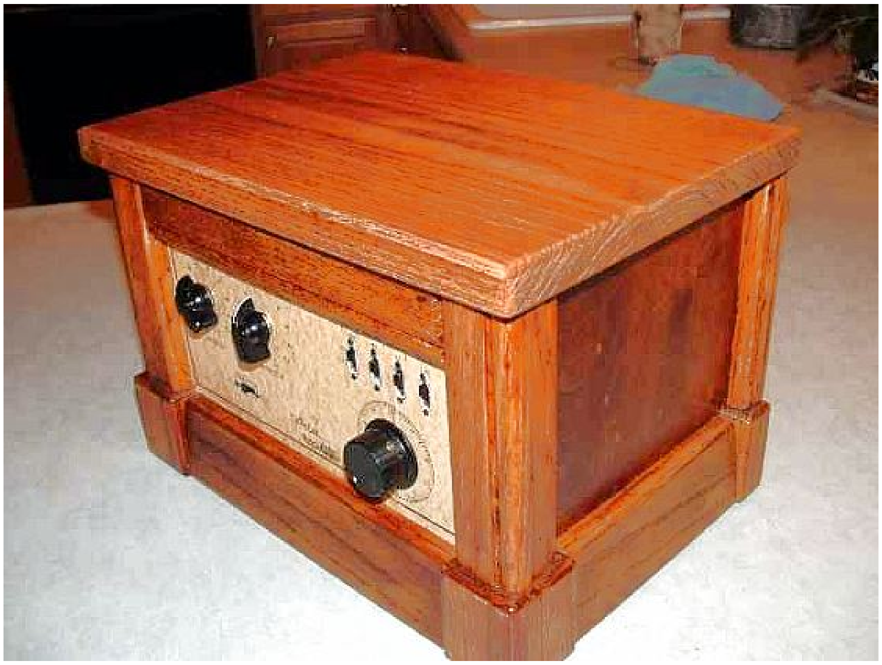
Mark Hampton



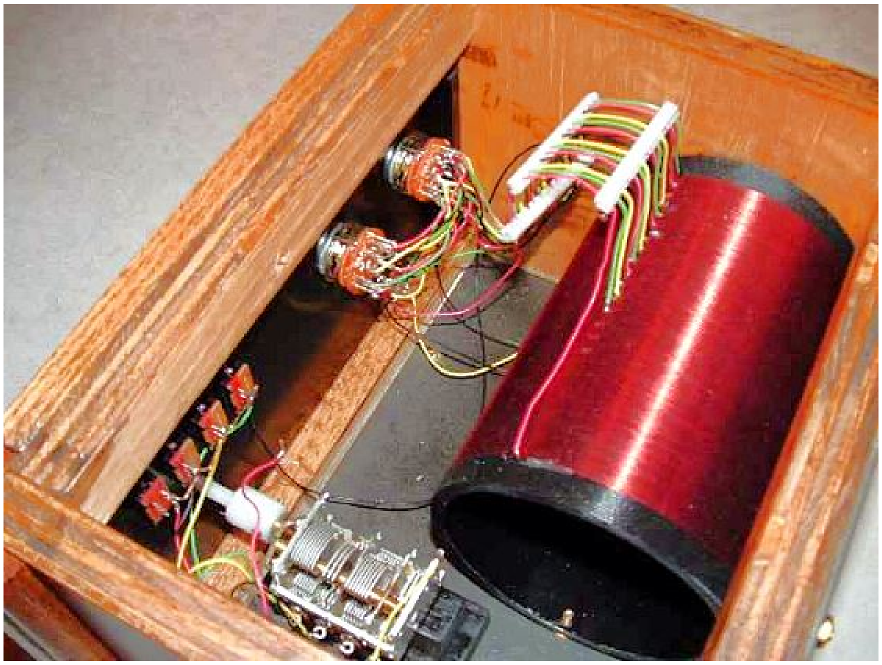
My interest in crystal radios was less than a month old when I found out about the DX contest. The result is my entry which, for reasons that will become obvious, I have dubbed the Comedyne. If you find any of this humorous rest assured that you are laughing with me and not at me.

I entered the formula for calculating coils into a spreadsheet. Later on I modified the formula so that I could enter the diameter instead of the radius and promptly forgot that I had done so. The coil form I used was 4 inch PVC that I turned down and threaded at 22 TPI. When I went to calculate the length I entered a 2 instead of 4 and came up with a length of 5 inches. This resulted in a coil of 800 uH instead of the 280 to 300 uH that I wanted. I was too green to recognize that this was not right and of course the coil was all soldered up before I found my mistake.

The one thing that went right on the coil was the winding and tapping. I had tried various methods of making taps on a coil with little success. Seems I don't have the patience, eyesight and requisite number of arms to do a decent job of it so I came up with a new (at least to me) idea. I drilled line of small holes at every 5th thread. I placed the coil form in the freezer for a while to shrink it and then quickly wound the coil. Then I scraped the enamel off each wire that passed over a hole with a sharp pointed hobby knife. I bent a small hook in the end of each tap wire passed it through the hole, turned it 90 deg and "hooked" the winding. I placed a tiny dab of flux on the wire and then folded the tag end of the hook down tight on the coil. A dab of solder finished the job. The result was a nice tight, neat (if slightly over-wound) coil. I bridged all the taps together with a loom to help take the stress off of the solder joints.

The only caps I had were some I ordered from Antique Electronics to play with because they were cheap. They are 4 section totaling 240pf and 540 deg. rotation. I found out why they are so cheap. Nobody in his right mind would want a VC designed for PC board mounting. I finally figured out a way to mount them and only destroyed one in the process. I didn't have time to order a shaft extension so I machined one out of some plastic rod.

When selecting a diode from two dozen 34As two of them accidentally touched together and the sound level really jumped up. I called them a pair and mated them forever. My antenna is an almost 300 foot wire running due north/south. It ranges from 15 to 20 feet off the ground. The ground is a piece of ½ inch black pipe driven 6 feet into the ground.



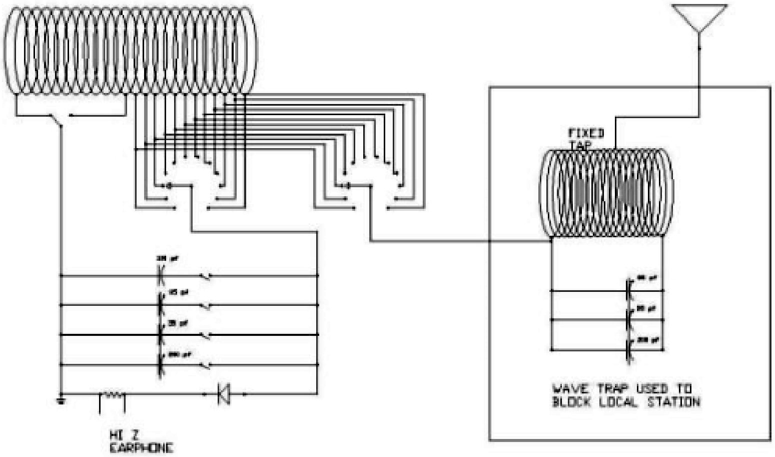
I used 12 pos. rotary switches from Antique Electronics for the antenna and tuner taps. For the other switches I used the slide type strictly for looks. (Certainly not for the "ease" of mounting!) The tuning knob and slide switches are from Radio Shack.

Four of the slide switches are for the capacity. 200pf, 30pf, and 85pf on the variable and a 150pf fixed cap. The other switches the ground to switch out half the coil. My grand plan was to be able to do some short wave tuning. (I did manage to do some.)

I'm an admirer of Art Deco and Arts and Crafts design so I set out to make a case for the radio that would look at home in a room designed by Frank Loyd Wright. I also wanted it to look like it had been around for 50 or 60 years. The sides are the very last scraps of some birch plywood from a project I did over 6 years ago. The remainder is solid oak and some oak trim that I modified. An artfully sloppy stain job (left dark in cracks and crevi and lighter on the corners and edges) with Minwax English Chestnut stain gives the look of age. It is finished with three coats of Deft semi-gloss. I am more or less pleased with the result. The trim above the faceplate is a little too wide and I'm not crazy about the flat top. I may do something about the top.

The faceplate is 1/8 in plastic that I found laying around the engineering shop at work. I made a milling template on Autocad and adhered it to the plate. After milling I soaked it off with some WD-40. I then modified the Cad drawing for the graphics and printed it out on some parchment looking card stock that I found at Hobby Lobby. Adhering the graphic onto the faceplate in proper alignment was another comedy of errors. Needless to say there are come creases and wrinkles that worked out perfectly in my plan for the "aged" look. Two coats of spray poly were applied to protect the paper.

The back plate is a 97-cent clipboard from Wal-Mart. I cut it to fit and shot it with some cheap black spray paint. It has the perfect cheap-black-fiberboard-radio-back appearance. Maybe because that's what it is.



The set tuned very broadly. That may have to do with the huge coil. A local was smeared all over the dial in the daytime and half of it at night. A hastily constructed trap was used to block the local until they signed off at 11PM. Then I would reconnect the antenna directly to my set. Even switching out half of the coil had little effect on the selectivity. Strong stations like WHO and WWL covered a lot of my tuning range. Using the trap as an antenna tuner may have helped but I wanted to stay within the hobby class regulations.

Still I think I did pretty well. I managed to get about 35 stations for a score of just over 55,000 points. The furthest was CBC in Vancouver BC. I will wind a proper coil for the set when time allows.

...Turned out to be quite a contest. Conditions were very flat until the second Friday (20 Jan.); then propagation really picked up. Area T-storms produced a moderate static level Sat. & yesterday, but good prop. seemed to persist.

Same set as last year's event, except I did put a lead telluride rockstand on the stronger local stations. (This was the same detector I heard KRVN 880 Nebraska on several contests back. But that was on the Lyonodyne 17 set.)

Two of the stations heard were new: KXTK 1280 never heard before on any set; CFAC 960 first heard in last year's 1-AD contest.

Mercifully a clandestine neighborhood super noise source held off during prime listening hours …

[57] **ABSTRACT**

Methods and apparatus for releasing energy from hydrogen atoms (molecules) by stimulating their electrons to relax to quantized lower energy levels and smaller radii (smaller semimajor and semiminor axes) than the "ground state" by providing energy sinks or means to remove energy resonant with the hydrogen energy released to stimulate these transitions. An energy sink, energy hole, can be provided by the transfer of at least one electron between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more donating species to one or more accepting species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron accepting species equals approximately mX27.21 eV (mX48.6 eV) for atomic (molecular) hydrogen below "ground state" transitions where m and t are integers. The present invention further comprises a hydrogen spillover catalyst, a multifunctionality material having a functionality which dissociates molecular hydrogen to provide free hydrogen atoms which spill over to a functionality which supports mobile free hydrogen atoms and a functionality which can be a source of the energy holes. The energy reactor includes one of an electrolytic cell, a pressurized hydrogen gas cell, and a hydrogen gas discharge cell. A preferred pressurized hydrogen gas energy reactor comprises a vessel; a source of hydrogen; a means to control the pressure and flow of hydrogen into the vessel; a material to dissociate the molecular hydrogen into atomic hydrogen, and a material which can be a source of energy holes in the gas phase. The gaseous source of energy holes includes those that sublime, boil, and/or are volatile at the elevated operating temperature of the gas energy reactor wherein the exothermic reaction of electronic transitions of hydrogen to lower energy states occurs in the gas phase.

LOWER-ENERGY HYDROGEN METHODS AND STRUCTURES

This application is a continuation of U.S. patent application Ser. No. 08/592,712, filed Jan. 26, 1996, abandoned.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to methods and apparatus for releasing energy from hydrogen atoms (molecules) as their electrons are stimulated to relax to lower energy levels and smaller radii (smaller semimajor and semiminor axes) than the "ground state" by providing a transition catalyst which acts as an energy sink or means to remove energy resonant with the electronic energy released to stimulate these transitions according to a novel atomic model. The transition catalyst should not be consumed in the reaction. It accepts energy from hydrogen and releases the energy to the surroundings. Thus, the transition catalyst returns to the origin state. Processes that require collisions are common. For example, the exothermic chemical reaction of H+H to form H_2 requires a collision with a third body, M, to remove the bond energy–$H+H+M \rightarrow H_2+M$. The third body distributes the energy from the exothermic reaction, and the end result is the H_2 molecule and an increase in the temperature of the system. Similarly, the transition from the n=1 state of hydrogen to the

$$n = \frac{1}{\text{integer}}$$

states of hydrogen is possible via a resonant collision, say n=1 to n=½. In these cases, during the collision the electron (s) couples to another electron transition or electron transfer reaction, for example, which can absorb the exact amount of energy that must be removed from the hydrogen atom (molecule), a resonant energy sink. The end result is a lower-energy state for the hydrogen and increase in temperature of the system. Each of such reactions is hereafter referred to as a shrinkage reaction: each transition is hereafter referred to as a shrinkage transition; each energy sink or means to remove energy resonant with the hydrogen electronic energy released to effect each transition is hereafter referred to as an energy hole, and the electronic energy removed by the energy hole to effect or stimulate the shrinkage transition is hereafter referred to as the resonance shrinkage energy. An energy hole comprising a reactant ion that is spontaneously regenerated following an endothermic electron ionization reaction of energy equal to the resonance shrinkage energy is hereafter referred to as an electrocatalytic ion. An energy hole comprising two reactants that are spontaneously regenerated following the an endothermic electron transfer reaction between the two species wherein the differences in their ionization energies is equal to the resonance shrinkage energy is hereafter referred to as an electrocatalytic couple.

The present invention of an electrolytic cell energy reactor, pressurized gas energy reactor, and a gas discharge energy reactor, comprises: a source of hydrogen; one of a solid, molten, liquid, and gaseous source of energy holes; a vessel containing hydrogen and the source of energy holes wherein the shrinkage reaction occurs by contact of the hydrogen with the source of energy holes; and a means for removing, the (molecular) lower-energy hydrogen so as to prevent an exothermic shrinkage reaction from coming to equilibrium. The present invention further comprises methods and structures for repeating this shrinkage reaction to produce shrunken atoms (molecules) to provide new materials with novel properties such as high thermal stability.

2. Description of the Related Art

Existing atomic models and theories are unable to explain certain observed physical phenomena. The Schrödinger wavefunctions of the hydrogen atom, for example, do not explain the extreme ultraviolet emission spectrum of the interstellar medium or that of the Sun, as well as the phenomenon of anomalous heat release from hydrogen in certain electrolytic cells having a potassium carbonate electrolyte or certain gas energy cells having a hydrogen spillover catalyst comprising potassium nitrate with the production of lower-energy hydrogen atoms and molecules, which is part of the present invention. Thus, advances in energy production and materials have been largely limited to laboratory discoveries having limited or sub-optimal commercial application.

SUMMARY OF THE INVENTION

The present invention comprises methods and apparatuses for releasing heat energy from hydrogen atoms (molecules) by stimulating their electrons to relax to quantized potential energy levels below that of the "ground state" via electron transfer reactions of reactants including electrochemical reactant(s) (electrocatalytic ion(s) or couple(s)) which remove energy from the hydrogen atoms (molecules) to stimulate these transitions. In addition, this application includes methods and apparatuses to enhance the power output by enhancing the reaction rate- the rate of the formation of the lower-energy hydrogen. The present invention further comprises a hydrogen spillover catalyst, a multifunctionality material having a functionality which dissociates molecular hydrogen to provide free hydrogen atoms which spill over to a functionality which supports mobile free hydrogen atoms and a functionality which can be a source of the energy holes. The energy reactor includes one of an electrolytic cell, a pressurized hydrogen gas cell, and a hydrogen gas discharge cell.

A preferred pressurized hydrogen gas energy reactor comprises a vessel; a source of hydrogen; a means to control the pressure and flow of hydrogen into the vessel; a material to dissociate the molecular hydrogen into atomic hydrogen, and a material which can be a source of energy holes in the gas phase. The gaseous source of energy holes includes those that sublime, boil, and/or are volatile at the elevated operating temperature of the gas energy reactor wherein the shrinkage reaction occurs in the gas phase.

The present invention further comprises methods and apparatuses for repeating a shrinkage reaction according to the present invention to cause energy release and to provide shrunken atoms and molecules with novel properties such as high thermal stability, and low reactivity. The lower-energy state atoms and molecules are useful for heat transfer, cryogenic applications, as a buoyant gas. as a medium in an engine such as a Sterling engine or a turbine, as a general replacement for helium, and as a refrigerant by absorbing energy including heat energy as the electrons are excited back to a higher energy level.

Below "Ground State" Transitions of Hydrogen Atoms

A novel atomic theory is disclosed in Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa. provided by HydroCatalysis Power Corporation, Great Valley Corporate Center, 41 Great Valley Parkway, Malvern, Pa. 19355; *The Unification of Spacetime, the Forces, Matter, and Energy*, Mills, R., Technomic Publishing Company, Lancaster, Pa., (1992); *The Grand Unified Theory*, Mills, R. and Farrell, J., Science Press, Ephrata, Pa., (1990); Mills, R., Kneizys, S., Fusion Technology, 210, (1991), pp. 65–81; Mills, R., Good, W., Shaubach, R., "Dihydrino Molecule Identification", Fusion Technology, 25, 103 (1994); Mills, R., Good, W., "Fractional Quantum Energy Levels of Hydrogen", Fusion Technology, Vol. 28. No. 4, November, (1995), pp. 1697–1719, and in my previous U.S. patent applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989 which are all incorporated herein by this reference.

Fractional Quantum Energy Levels of Hydrogen

A number of experimental observations given in the Experimental Section below lead to the conclusion that atomic hydrogen can exist in fractional quantum states that are at lower energies than the traditional "ground" (n=1) state. For example, existence of fractional-quantum-energy-level hydrogen atoms, hereafter called hydrinos, provides an explanation for the soft X-ray emissions of the dark interstellar medium observed by Labov and Bowyer [S. Labov and S. Bowyer, Astrophysical Journal, 371 (1991) 810] and an explanation for the soft X-ray emissions of the Sun [Thomas, R. J., Neupert, W., M., Astrophysical Journal Supplement Series, Vol. 91, (1994), pp. 461–482; Malinovsky, M., Heroux, L., Astrophysical Journal, Vol. 181, (1973), pp. 1009–1030; Noyes, R., *The Sun, Our Star*, Harvard University Press, Cambridge, Ma., (1982), p. 172; Phillips, J. H., *Guide to the Sun*, Cambridge University Press, Cambridge, Great Britain, (1992), pp. 118–119; 120–121; 144–145].

J. J. Balmer showed in 1885 that the frequencies for some of the lines observed in the emission spectrum of atomic hydrogen could be expressed with a completely empirical relationship. This approach was later extended by J. R. Rydberg, who showed that all of the spectral lines of atomic hydrogen were given by the equation:

$$\bar{\nu} = R\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right) \tag{1}$$

where R=109,677 cm^{-1}, n_f=1,2,3, . . . , n_i=2,3,4, . . . , and $n_i > n_f$. Niels Bohr, in 1913, developed a theory for atomic hydrogen that gave energy levels in agreement with Rydberg's equation. An identical equation, based on a totally different theory for the hydrogen atom, was developed by E. Schrödinger, and independently by W. Heisenberg, in 1926.

$$E_n = -\frac{e^2}{n^2 8\pi\varepsilon_o a_H} = \frac{13.598\text{ eV}}{n^2} \tag{2a}$$

$$n = 1, 2, 3, \ldots \tag{2b}$$

where a_H is the Bohr radius for the hydrogen atom (52.947 pm), e is the magnitude of the charge of the electron, and ϵ_o is the vacuum permittivity. Mills' theory predicts that Eq. (2b), should be replaced by Eq. (2c).

$$n = 1, 2, 3, \ldots, \text{and}, n = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots \tag{2c}$$

The quantum number n=1 is routinely used to describe the "ground" electronic state of the hydrogen atom. Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.] in a recent advancement of quantum mechanics has shown that the n=1 state is the "ground" state for "pure" photon transitions (the n=1 state can absorb a photon and go to an excited electronic state, but it cannot release a photon and go to a lower-energy electronic state). However, an electron transition from the ground state to a lower-energy state is possible by a "resonant collision" mechanism. These lower-energy states have fractional quantum numbers,

$$n = \frac{1}{\text{integer}}.$$

Processes that occur without photons and that require collisions are common. For example, the exothermic chemical reaction of H+H to form H_2 does not occur with the emission of a photon. Rather, the reaction requires a collision with a third body, M, to remove the bond energy–$H+H+M \rightarrow H_2+M$. The third body distributes the energy from the exothermic reaction, and the end result is the H_2 molecule and an increase in the temperature of the system. Similarly, the n=1 state of hydrogen and the

$$n = \frac{1}{\text{integer}}$$

states of hydrogen are nonradiative, but a transition between two nonradiative states is possible via a resonant collision, say n=1 to n=½. In these cases, during the collision the electron couples to another electron transition or electron transfer reaction which can absorb the exact amount of energy that must be removed from the hydrogen atom, a resonant energy sink called an energy hole. The end result is a lower-energy state for the hydrogen and increase in temperature of the system.

Wave Equation Solutions of the Hydrogen Atom

Recently, Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.] has built on the work generally known as quantum mechanics by deriving a new atomic theory based on first principles. The novel theory hereafter referred to as Mills' theory unifies Maxwell's Equations, Newton's Laws, and Einstein's General and Special Relativity. The central feature of this theory is that all particles (atomic-size and macroscopic particles) obey the same physical laws. Whereas Schrödinger postulated a boundary condition: $\Psi \rightarrow 0$ as $r \rightarrow \infty$, the boundary condition in Mills' theory was derived from Maxwell's equations [Haus, H. A., "On the radiation from point charges", American Journal of Physics, 54, (1986), pp. 1126–1129.]:

> For non-radiative states, the current-density function must not possess space-time Fourier components that are synchronous with waves traveling at the speed of light.

Application of this boundary condition leads to a physical model of particles, atoms, molecules, and, in the final analysis, cosmology. The closed-form mathematical solutions contain fundamental constants only, and the calculated values for physical quantities agree with experimental observations. In addition, the theory predicts that Eq. (2b), should be replaced by Eq. (2c).

Bound electrons are described by a charge-density (mass-density) function which is the product of a radial delta function ($f(r)=\delta(r-r_n)$), two angular functions (spherical harmonic functions), and a time harmonic function. Thus, an electron is a spinning, two-dimensional spherical surface, hereafter called an electron orbitsphere, that can exist in a bound state at only specified distances from the nucleus. More explicitly, the orbitsphere comprises a two dimensional spherical shell of moving charge. The corresponding current pattern of the orbitsphere comprises an infinite series of correlated orthogonal great circle current loops. The current pattern (shown in FIG. 1.4 of Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.]) is generated over the surface by two orthogonal sets of an infinite series of nested rotations of two orthogonal great circle current loops where the coordinate axes rotate with the two orthogonal great circles. Each infinitesimal rotation of the infinite series is about the new x-axis and new y-axis which results from the preceding such rotation. For each of the two sets of nested rotations, the angular sum of the rotations about each rotating x-axis and y-axis totals $\sqrt{2}\,\pi$ radians. The current pattern gives rise to the phenomenon corresponding to the spin quantum number.

The total function that describes the spinning motion of each electron orbitsphere is composed of two functions. One function, the spin function, is spatially uniform over the orbitsphere, spins with a quantized angular velocity, and gives rise to spin angular momentum. The other function, the modulation function, can be spatially uniform—in which case there is no orbital angular momentum and the magnetic moment of the electron orbitsphere is one Bohr magneton—or not spatially uniform—in which case there is orbital angular momentum. The modulation function also rotates with a quantized angular velocity. Numerical values for the angular velocity, radii of allowed orbitspheres. energies, and associated quantities are calculated by Mills.

Orbitsphere radii are calculated by setting the centripetal force equal to the electric and magnetic forces.

The orbitsphere is a resonator cavity which traps photons of discrete frequencies. The radius of an orbitsphere increases with the absorption of electromagnetic energy. The solutions to Maxwell's equations for modes that can be excited in the orbitsphere resonator cavity give rise to four quantum numbers, and the energies of the modes are the experimentally known hydrogen spectrum.

Excited states are unstable because the charge-density function of the electron plus photon have a radial doublet function component which corresponds to an electric dipole. The doublet possesses spacetime Fourier components synchronous with waves traveling at the speed of light; thus it is radiative. The charge-density function of the electron plus photon for the n=1 principle quantum state of the hydrogen atom as well as for each of the

$$n = \frac{1}{\text{integer}}$$

states mathematically is purely a radial delta function. The delta function does not possess spacetime Fourier components synchronous with waves traveling at the speed of light; thus, each is nonradiative.

Catalytic Lower-energy Hydrogen Electronic Transitions

Comparing transitions between below "ground" (fractional quantum) energy states as opposed to transitions between excited (integer quantum) energy states, it can be appreciated that the former are not effected by photons; whereas, the latter are. Transitions are symmetric with respect to time. Current density functions which give rise to photons according to the nonradiative boundary condition of Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.] are created by photons in the reverse process. Excited (integer quantum) energy states correspond to this case. And, current density functions which do not give rise to photons according to the nonradiative boundary condition are not created by photons in the reverse process. Below "ground" (fractional quantum) energy states correspond to this case. But, atomic collisions can cause a stable state to undergo a transition to the next stable state. The transition between two stable nonradiative states effected by a collision with an resonant energy sink is analogous to the reaction of two atoms to form a diatomic molecule which requires a third-body collision to remove the bond energy [N. V. Sidgwick, *The Chemical Elements and Their Compounds*, Volume I, Oxford, Clarendon Press, (1950), p. 17].

Energy Hole Concept

The nonradiative boundary condition of Mills and the relationship between the electron and the photon give the "allowed" hydrogen energy states which are quantized as a function of the parameter n. Each value of n corresponds to an allowed transition effected by a resonant photon which excites the electronic transition. In addition to the traditional integer values (1, 2, 3, . . . ,) of n, values of fractions are allowed which correspond to transitions with an increase in the central field (charge) and decrease in the size of the hydrogen atom. This occurs, for example, when the electron couples to another electronic transition or electron transfer reaction which can absorb energy, an energy sink. This is the absorption of an energy hole. The absorption of an energy hole destroys the balance between the centrifugal force and the increased central electric force. As a result, the electron undergoes a transition to a lower energy nonradiative state.

From energy conservation, the resonance energy hole of a hydrogen atom which excites resonator modes of radial dimensions

$$\frac{a_H}{m+1}$$

is

$$mX27.2\ \text{eV where } m=1,2,3,4,\ldots \tag{3}$$

After resonant absorption of the energy hole, the radius of the orbitsphere, a_H, shrinks to

$$\frac{a_H}{m+1}$$

and after p cycles of resonant shrinkage, the radius is

$$\frac{a_H}{mp+1}.$$

In other words, the radial ground state field can be considered as the superposition of Fourier components. The removal of negative Fourier components of energy mX27.2 eV, where m is an integer increases the positive central electric field inside the spherical shell by m times the charge of a proton. The resultant electric field is a time-harmonic solution of Laplace's Equations in spherical coordinates. In this case, the radius at which force balance and nonradiation are achieved is

$$\frac{a_H}{m+1}$$

where m is an integer. In decaying to this radius from the "ground" state, a total energy of $[(m+1)^2-1^2]$X13.6 eV is released. The transition between two stable nonradiative states effected by a collision with an energy hole is analogous to the reaction of two atoms to form a diatomic molecule which requires a third body collision to remove the bond energy [N. V. Sidgwick, *The Chemical Elements and Their Compounds*, Volume I, Oxford, Clarendon Press, (1950), p. 17]. The total energy well of the hydrogen atom is shown in FIG. **1**. The exothermic reaction involving transitions from one potential energy level to a lower level is hereafter referred to as HydroCatalysis.

A hydrogen atom with its electron in a lower than "ground state" energy level corresponding to a fractional quantum number is hereafter referred to as a hydrino atom. The designation for a hydrino atom of radius

$$\frac{a_o}{p}$$

where p is an integer is

$$H\left[\frac{a_o}{p}\right].$$

The size of the electron orbitsphere as a function of potential energy is given in FIG. **2**.

An efficient catalytic system that hinges on the coupling of three resonator cavities involves potassium. For example, the second ionization energy of potassium is 31.63 eV. This energy hole is obviously too high for resonant absorption. However, K^+ releases 4.34 eV when it is reduced to K. The combination of K^+ to K^{2+} and K^+ to K, then, has a net energy change of 27.28 eV.

$$27.28\text{ eV} + K^+ + K^+ + H\left[\frac{a_H}{p}\right] \to K + K^{2+} + H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{4}$$

$$K + K^{2+} \to K^+ + K^+ + 27.28\text{ eV} \tag{5}$$

And, the overall reaction is

$$H\left[\frac{a_H}{p}\right] \to H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{6}$$

Note that the energy given off as the atom shrinks is much greater than the energy lost to the energy hole. Also, the energy released is large compared to conventional chemical reactions.

Disproportionation of Energy States

Lower-energy hydrogen atoms, hydrinos, can act as a source of energy holes that can cause resonant shrinkage because the excitation and/or ionization energies are mX27.2 eV (Eq. (3)). For example, the equation for the absorption of an energy hole of 27.21 eV, m=1 in Eq. (3), during the shrinkage cascade for the third cycle of the hydrogen-type atom,

$$H\left[\frac{a_H}{3}\right],$$

with the hydrogen-type atom,

$$H\left[\frac{a_H}{2}\right],$$

that is ionized as the source of energy holes that cause resonant shrinkage is represented by

$$27.21\text{ eV} + H\left[\frac{a_H}{2}\right] + H\left[\frac{a_H}{3}\right] \to H^+ + e^- + H\left[\frac{a_H}{4}\right] + [4^2 - 3^2] \times 13.6\text{ eV} - 27.21\text{ eV} \tag{7}$$

$$H^+ + e^- \to H\left[\frac{a_H}{1}\right] + 13.6\text{ eV} \tag{8}$$

And, the overall reaction is

$$H\left[\frac{a_H}{2}\right] + H\left[\frac{a_H}{3}\right] \to H\left[\frac{a_H}{1}\right] + H\left[\frac{a_H}{4}\right] + [4^2 - 3^2 - 4] \times 13.6\text{ eV} + 13.6\text{ eV} \tag{9}$$

The general equation for the absorption of an energy hole of 27.21 eV, m=1 in Eq. (3), during the shrinkage cascade for the pth cycle of the hydrogen-type atom,

$$H\left[\frac{a_H}{p}\right],$$

with the hydrogen-type atom,

$$H\left[\frac{a_H}{m'}\right],$$

that is ionized as the source of energy holes that cause resonant shrinkage is represented by

$$27.21\text{ eV} + H\left[\frac{a_H}{m'}\right] + H\left[\frac{a_H}{p}\right] \to H^+ + e^- + H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} - (m'^2 - 2) \times 13.6\text{ eV} \tag{10}$$

$$H^+ + e^- \to H\left[\frac{a_H}{1}\right] + 13.6\text{ eV} \tag{11}$$

And, the overall reaction is

$$H\left[\frac{a_H}{m'}\right] + H\left[\frac{a_H}{p}\right] \to H\left[\frac{a_H}{1}\right] + H\left[\frac{a_H}{(p+1)}\right] + [2p + 1 - m'^2] \times 13.6\text{ eV} + 13.6\text{ eV} \tag{12}$$

Transitions to nonconsecutive energy levels involving the absorption of an energy hole of an integer multiple of 27.21 eV are possible. Lower-energy hydrogen atoms, hydrinos, can act as a source of energy holes that can cause resonant shrinkage with the absorption of an energy hole of mX27.2 eV (Eq. (3)). Thus, the shrinkage cascade for the pth cycle of the hydrogen-type atom,

$$H\left[\frac{a_H}{p}\right],$$

with the hydrogen-type atom,

$$H\left[\frac{a_H}{m'}\right],$$

that is ionized as the source of energy holes that cause resonant shrinkage is represented by

$$m \times 27.21\text{ eV} + H\left[\frac{a_H}{m'}\right] + H\left[\frac{a_H}{p}\right] \rightarrow \tag{13}$$

$$H^+ + e^- + H\left[\frac{a_H}{(p+m)}\right] + [(p+m)^2 - p^2 - (m'^2 - 2m)] \times 13.6\text{ eV}$$

$$H^+ + e^- \rightarrow H\left[\frac{a_H}{1}\right] + 13.6\text{ eV} \tag{14}$$

And, the overall reaction is

$$H\left[\frac{a_H}{m'}\right] + H\left[\frac{a_H}{p}\right] \rightarrow \tag{15}$$

$$H\left[\frac{a_H}{1}\right] + H\left[\frac{a_H}{(p+m)}\right] + [2pm + m^2 - m'^2] \times 13.6\text{ eV} + 13.6\text{ eV}$$

Hydrogen is a source of energy holes. The ionization energy of hydrogen is 13.6 eV. Disproportionation can occur between three hydrogen atoms whereby two atoms provide an energy hole of 27.21 eV for the third hydrogen atom. Thus, the shrinkage cascade for the pth cycle of the hydrogen-type atom,

$$H\left[\frac{a_H}{p}\right],$$

with two hydrogen atoms,

$$H\left[\frac{a_H}{1}\right],$$

as the source of energy holes that cause resonant shrinkage is represented by

$$27.21\text{ eV} + 2H\left[\frac{a_H}{1}\right] + H\left[\frac{a_H}{p}\right] \rightarrow \tag{16}$$

$$2H^+ + 2e^- + H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV}$$

$$2H^+ + 2e^- \rightarrow 2H\left[\frac{a_H}{1}\right] + 27.21\text{ eV} \tag{17}$$

And, the overall reaction is

$$H\left[\frac{a_H}{p}\right] \rightarrow H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p] \times 13.6\text{ eV} \tag{18}$$

The spectral lines from dark interstellar medium and the majority of the solar power can be attributed to disproportionation reactions as given in the Spectral Data of Hydrinos from the Dark Interstellar Medium and from the Sun Section of Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.]. This assignment resolves the mystery of dark matter, the solar neutrino problem, and the mystery of the cause of sunspots and other solar activity and why the Sun emits X-rays. It also provides the reason for the abrupt change in the speed of sound and transition from "radiation zone" to "convection zone" at a radius of 0.7 the solar radius, 0.7 R_s as summarized in Example 4 below.

Energy Hole (Atomic Hydrogen)

In a preferred embodiment, energy holes, each of approximately 27.21 eV, are provided by electron transfer reactions of reactants including electrochemical reactant(s) (electrocatalytic ion(s) or couple(s)) which cause heat to be released from hydrogen atoms as their electrons are stimulated to relax to quantized potential energy levels below that of the "ground state". The energy removed by an electron transfer reaction, energy hole, is resonant with the hydrogen energy released to stimulate this transition. The source of hydrogen atoms can be the production on the surface of a cathode during electrolysis of water in the case of an electrolytic energy reactor and hydrogen gas or a hydride in the case of a pressurized gas energy reactor or gas discharge energy reactor.

Below "Ground State" Transitions of Hydrogen-type Molecules and Molecular Ions

Two hydrogen atoms react to form a diatomic molecule, the hydrogen molecule.

$$2H[a_H] \rightarrow H_2[2c' = \sqrt{2}\,a_o] \tag{19}$$

where 2c' is the internuclear distance. Also, two hydrino atoms react to form a diatomic molecule, hereafter called a dihydrino molecule.

$$2H\left[\frac{a_H}{p}\right] \rightarrow H_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{p}\right] \tag{20}$$

where p is an integer.

The central force equation for hydrogen-type molecules has orbital solutions which are circular, elliptic, parabolic, or hyperbolic. The former two types of solutions are associated with atomic and molecular orbitals. These solutions are nonradiative if the boundary condition for nonradiation given in the One Electron Atom Section of *The Unification of Spacetime, the Forces, Matter, and Energy*, Mills, R., Technomic Publishing Company, Lancaster, Pa., (1992), is met. The mathematical formulation for zero radiation is that the function that describes the motion of the electron must not possess space-time Fourier components that are synchronous with waves traveling at the speed of light. The boundary condition for the orbitsphere is met when the angular frequencies are

$$\omega_n = \frac{\hbar}{m_e r_n^2} \tag{21}$$

As demonstrated in the One Electron Atom Section of *The Unification of Spacetime, the Forces, Matter, and Energy*, Mills, R., Technomic Publishing Company, Lancaster, Pa., (1992), this condition is met for the product function of a radial Dirac delta function and a time harmonic function where the angular frequency, ω, is constant and given by Eq. (21).

$$\omega_n = \frac{\hbar}{m_e r_n^2} = \frac{\frac{\pi L}{m_e}}{A} \tag{22}$$

where L is the angular momentum and A is the area of the closed geodesic orbit. Consider the solution of the central force equation comprising the product of a two dimensional ellipsoid and a time harmonic function. The spatial part of the product function is the convolution of a radial Dirac delta function with the equation of an ellipsoid. The Fourier transform of the convolution of two functions is the product of the individual Fourier transforms of the functions: thus, the boundary condition is met for an ellipsoidal-time harmonic function when

$$\omega_n = \frac{\pi\hbar}{m_e A} = \frac{\hbar}{m_e ab} \tag{23}$$

where the area of an ellipse is

$$A=\pi ab \tag{24}$$

where 2b is the length of the semiminor axis and 2a is the length of the semimajor axis. The geometry of molecular hydrogen is elliptic with the internuclear axis as the principle axis; thus, the electron orbital is a two dimensional ellipsoidal-time harmonic function. The mass follows geodesics time harmonically as determined by the central field of the protons at the foci. Rotational symmetry about the internuclear axis further determines that the orbital is a prolate spheroid. In general, ellipsoidal orbits of molecular bonding, hereafter referred to as ellipsoidal molecular orbitals (M. O.'s), have the general equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \tag{25}$$

The semiprinciple axes of the ellipsoid are a, b, c.

In ellipsoidal coordinates the Laplacian is

$$(\eta - \zeta)R_\xi \frac{\delta}{\delta\xi}\left(R_\xi \delta \frac{\phi}{\delta\xi}\right) + (\zeta - \xi)R_\eta \frac{\delta}{\delta\eta}\left(R_\eta \delta \frac{o}{\delta\eta}\right) + (\xi - \eta)R_\zeta \frac{\delta}{\delta\zeta}\left(R_\zeta \delta \frac{\phi}{\delta\zeta}\right) = 0 \tag{26}$$

An ellipsoidal M. O. is equivalent to a charged conductor whose surface is given by Eq. (25). It carries a total charge q, and it's potential is a solution of the Laplacian in ellipsoidal coordinates, Eq. (26).

Excited states of orbitspheres are discussed in the Excited States of the One Electron Atom (Quantization) Section of *The Unification of Spacetime, the Forces, Matter, and Energy*, Mills, R., Technomic Publishing Company, Lancaster, Pa., (1992). In the case of ellipsoidal M. O.'s, excited electronic states are created when photons of discrete frequencies are trapped in the ellipsoidal resonator cavity of the M. O. The photon changes the effective charge at the M. O. surface where the central field is ellipsoidal. Force balance is achieved at a series of ellipsoidal equipotential two dimensional surfaces confocal with the ground state ellipsoid. The trapped photons are solutions of the Laplacian in ellipsoidal coordinates, Eq. (26).

As is the case with the orbitsphere, higher and lower energy states are equally valid. The photon standing wave in both cases is a solution of the Laplacian in ellipsoidal coordinates. For an ellipsoidal resonator cavity, the relationship between an allowed circumference, 4aE, and the photon standing wavelength, λ, is

$$4aE=n\lambda \tag{27}$$

where n is an integer and where

$$k = \frac{\sqrt{a^2 - b^2}}{a} \tag{28}$$

is used in the elliptic integral E of Eq. (27). Applying Eqs. (27) and (28), the relationship between an allowed angular frequency given by Eq. (23) and the photon standing wave angular frequency, ω, is:

$$\frac{\pi\hbar}{m_e A} = \frac{\hbar}{m_e n a_1 n b_1} = \frac{\hbar}{m_e a_n b_n} = \frac{1}{n^2}\omega_1 = \omega_n \tag{29}$$

where n=1,2,3,4, . . .

$$n = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots$$

ω_1 is the allowed angular frequency for n=1 a_1 and b_1 are the allowed semimajor and semiminor axes for n=1

From Eq. (29), the magnitude of the elliptic field corresponding to a below "ground state" transition of the hydrogen molecule is an integer. The potential energy equations of hydrogen-type molecules are

$$V_e = \frac{-2pe^2}{8\pi\varepsilon_o\sqrt{a^2 - b^2}} \ln\frac{a + \sqrt{a^2 - b^2}}{a - \sqrt{a^2 - b^2}} \tag{30}$$

$$V_p = \frac{p}{8\pi\varepsilon_o} \frac{e^2}{\sqrt{a^2 - b^2}} \tag{31}$$

where

$$a = \frac{a_o}{p} \tag{32}$$

$$b = \frac{1}{p\sqrt{2}} a_o \tag{33}$$

$$c' = \sqrt{a^2 - b^2} = \frac{\sqrt{2}\, a_o}{2p} \tag{34}$$

and where p is an integer. From energy conservation, the resonance energy hole of a hydrogen-type molecule which causes the transition

$$\mathrm{H}_2^*\left[2c' = \frac{\sqrt{2}\, a_o}{p}\right] \rightarrow \mathrm{H}_2^*\left[2c' = \frac{\sqrt{2}\, a_o}{p + m}\right] \tag{35}$$

where m and p are integers. During the transition, the elliptic field is increased from magnitude p to magnitude p+m. The corresponding potential energy change equals the energy absorbed by the energy hole.

$$\text{Energy hole} = -V_e - V_p = mp^2 \text{X} 48.6 \text{ eV} \tag{37}$$

Further energy is released by the hydrogen-type molecule as the internuclear distance "shrinks". The total energy, E_T, released during the transition is

$$E_T = -13.6\text{ eV}\left[\left(2(m+p)^2\sqrt{2} - (m+p)^2\sqrt{2} + \frac{(m+p)^2\sqrt{2}}{2}\right)\ln\frac{\sqrt{2}+1}{\sqrt{2}-1} - (m+p)^2\sqrt{2}\right] + 13.6\text{ eV}\left[\left(2p^2\sqrt{2} - p^2\sqrt{2} + \frac{p^2\sqrt{2}}{2}\right)\ln\frac{\sqrt{2}+1}{\sqrt{2}-1} - p^2\sqrt{2}\right] \tag{38}$$

A schematic drawing of the total energy well of hydrogen-type molecules and molecular ions is given in FIG. **3**. The exothermic reaction involving transitions from one potential energy level to a lower level below the "ground state" is also hereafter referred to as HydroCatalysis.

A hydrogen-type molecule with its electrons in a lower than "ground state" energy level corresponding to a fractional quantum number is hereafter referred to as a dihydrino molecule. The designation for a dihydrino molecule of internuclear distance,

$$2c' = \frac{\sqrt{2}\,a_o}{p}$$

where p is an integer, is

$$H_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{p}\right].$$

A schematic drawing of the size of hydrogen-type molecules as a function of total energy is given in FIG. **4**.

The magnitude of the elliptic field corresponding to the first below "ground state" hydrogen-type molecule is 2. From energy conservation, the resonance energy hole of a hydrogen molecule which excites the transition of the hydrogen molecule with internuclear distance

$$2c' = \sqrt{2}\,a_o$$

to the first below "ground state" with internuclear distance

$$2c' = \frac{1}{\sqrt{2}}a_o$$

is given by Eqs. (30) and (31) where the elliptic field is increased from magnitude one to magnitude two:

$$V_e = \frac{-2e^2}{8\pi\varepsilon_o\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = -67.813\text{ eV} \tag{39}$$

$$V_p = \frac{e^2}{8\pi\varepsilon_o\sqrt{a^2-b^2}} = 19.23\text{ eV} \tag{40}$$

$$\text{Energy hole} = -V_e - V_p = m \times 48.6\text{ eV} \tag{41}$$

In other words, the ellipsoidal "ground state" field of the hydrogen molecule can be considered as the superposition of Fourier components. The removal of negative Fourier components of energy

$$m\text{X}48.6\text{ eV} \tag{42}$$

where m is an integer, increases the positive electric field inside the ellipsoidal shell by m times the charge of a proton at each focus. The resultant electric field is a time harmonic solution of the Laplacian in ellipsoidal coordinates. The hydrogen molecule with internuclear distance

$$2c' = \sqrt{2}\,a_o$$

is caused to undergo a transition to a below "ground state" level, and the internuclear distance for which force balance and nonradiation are achieved is

$$2c' = \frac{\sqrt{2}\,a_o}{1+m}.$$

In decaying to this internuclear distance from the "ground state", a total energy of

$$E_T = -13.6\text{ eV}\left[\left(2(1+m)^2\sqrt{2} - (1+m)^2\sqrt{2} + \frac{(1+m)^2\sqrt{2}}{2}\right)\ln\frac{\sqrt{2}+1}{\sqrt{2}-1} - (1+m)^2\sqrt{2}\right] + 13.6\text{ eV}\left[\left(2\sqrt{2} - \sqrt{2} + \frac{\sqrt{2}}{2}\right)\ln\frac{\sqrt{2}+1}{\sqrt{2}-1} - \sqrt{2}\right] \tag{43}$$

is released.

Energy Hole (Molecular Hydrogen)

In a preferred embodiment, energy holes, each of approximately mX48.6 eV, are provided by electron transfer reactions of reactants including electrochemical reactant(s) (electrocatalytic ion(s) or couple(s)) which cause heat to be released from hydrogen molecules as their electrons are stimulated to relax to quantized potential energy levels below that of the "ground state". The energy removed by an electron transfer reaction, energy hole, is resonant with the hydrogen energy released to stimulate this transition. The source of hydrogen molecules can be the production on the surface of a cathode during electrolysis of water in the case of an electrolytic energy reactor and hydrogen gas or a hydride in the case of a pressurized gas energy reactor or gas discharge energy reactor.

Energy Reactor

The present invention of an electrolytic cell energy reactor, pressurized gas energy reactor, and a gas discharge energy reactor, comprises: a source of hydrogen; one of a solid, molten, liquid, and gaseous source of energy holes; a vessel containing hydrogen and the source of energy holes wherein the shrinkage reaction occurs by contact of the hydrogen with the source of energy holes; and a means for removing the (molecular) lower-energy hydrogen so as to prevent the exothermic shrinkage reaction from coming to equilibrium. The shrinkage reaction rate and net power output are increased by conforming the energy hole to match the resonance shrinkage energy. In general, power output can be optimized by controlling the temperature, pressure of the hydrogen gas, the source of the energy hole including the electrocatalytic ion or couple which provides the energy hole, the counterion of the electrocatalytic ion or couple, and the area of the surface on which the shrinkage reaction occurs. The present invention further comprises a hydrogen spillover catalyst, a multifunctionality material having a functionality which dissociates molecular hydrogen to provide free hydrogen atoms which spill over to a functionality which supports mobile free hydrogen atoms and a functionality which can be a source of the energy holes.

A preferred pressurized hydrogen gas energy reactor comprises a vessel; a source of hydrogen; a means to control the pressure and flow of hydrogen into the vessel; a material to dissociate the molecular hydrogen into atomic hydrogen, and a material which can be a source of energy holes in the gas phase. The gaseous source of energy holes includes those that sublime, boil, and/or are volatile at the elevated operating temperature of the gas energy reactor wherein the shrinkage reaction occurs in the gas phase.

Other objects, features, and characteristics of the present invention, as well as the methods of operation and the functions of the related elements, will become apparent upon consideration of the following description and the appended claims with reference to the accompanying drawings, all of which form a part of this specification, wherein like reference numerals designate corresponding parts in the various figures.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a schematic drawing of the total energy well of the hydrogen atom;

FIG. **2** is a schematic drawing of the size of electron orbitspheres as a function of potential energy;

FIG. **3** is a schematic drawing of the total energy wells of the hydrogen molecule, $H_2[2c'=\sqrt{2}a_o]$, the hydrogen molecular ion, $H_2[2c'=2a_o]^+$, the dihydrino molecule,

$$H_2^*\left[2c' = \frac{a_o}{\sqrt{2}}\right],$$

and the dihydrino molecular ion, $H_2^*[2c'=a_o]^+$;

FIG. **4** is a schematic drawing of the size of hydrogen-type molecules,

$$H_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{p}\right],$$

as a function of total energy;

FIG. **5** is a schematic drawing of an energy reactor in accordance with the invention;

FIG. **6** is a schematic drawing of an electrolytic cell energy reactor in accordance with the present invention;

FIG. **7** is a schematic drawing of a pressurized gas energy reactor in accordance with the present invention;

FIG. **8** is a schematic drawing of a gas discharge energy reactor in accordance with the invention; and

FIG. **9** is a plot of the excess heat release from flowing hydrogen in the presence of nickel oxide powder containing strontium niobium oxide (Nb^{3+}/Sr^{2+} electrocatalytic couple) by the very accurate and reliable method of heat measurement, thermopile conversion of heat into an electrical output signal.

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENTS

CATALYTIC ENERGY HOLE STRUCTURE FOR ATOMS

Single Electron Excited State

An energy hole is provided by the transition of an electron of a species to an excited state species including a continuum excited state(s) of atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the excited state transition of an electron of one species whereby the transition energy of the accepting species equals approximately mX27.21 eV where m is an integer.

Single Electron Transfer

An energy hole is provided by the transfer of an electron between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of an electron from one species to another species whereby the sum of the ionization energy of the electron donating species minus the ionization energy or electron affinity of the electron accepting species equals approximately mX27.21 eV where m is an integer.

Single Electron Transfer (Two Species)

An efficient catalytic system that hinges on the coupling of three resonator cavities involves potassium. For example, the second ionization energy of potassium is 31.63 eV. This energy hole is obviously too high for resonant absorption. However, K^+ releases 4.34 eV when it is reduced to K. The combination of K^+ to K^{2+} and K^+ to K, then, has a net energy change of 27.28 eV; m=1 in Eq. (3).

$$27.28\text{ eV} + K^+ + K^+ + H\left[\frac{a_H}{p}\right] \to K + K^{2+} + H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{44}$$

$$K + K^{2+} \to K^+ + K^+ + 27.28\text{ eV} \tag{45}$$

And, the overall reaction is

$$H\left[\frac{a_H}{p}\right] \to H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{46}$$

Note that the energy given off as the atom shrinks is much greater than the energy lost to the energy hole. And, the energy released is large compared to conventional chemical reactions.

For sodium or sodium ions no electrocatalytic reaction of approximately 27.21 eV is possible. For example, 42.15 eV of energy is absorbed by the reverse of the reaction given in Eq. (45) where Na^+ replaces K^+:

$$Na^+ + Na^+ + 42.15\text{ eV} \to Na + Na^{2+} \tag{47}$$

Other less efficient catalytic systems hinge on the coupling of three resonator cavities. For example, the third ionization energy of palladium is 32.93 eV. This energy hole is obviously too high for resonant absorption. However, Li^+ releases 5.392 eV when it is reduced to Li. The combination of Pd^{2+} to Pd^{3+} and Li^+ to Li, then, has a net energy change of 27.54 eV.

$$27.54\text{ eV} + Li^+ + Pd^{2+} + H\left[\frac{a_H}{p}\right] \to Li + Pd^{3+} + H\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{48}$$

$$Li + Pd^{3+} \to Li^+ + Pd^{2+} + 27.54\text{ eV} \tag{49}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{50}$$

Single Electron Transfer (One Species)

An energy hole is provided by the ionization of an electron from a participating species including an atom, an ion, a molecule, and an ionic or molecular compound to a vacuum energy level. In one embodiment, the energy hole comprises the ionization of an electron from one species to a vacuum energy level whereby the ionization energy of the electron donating species equals approximately mX27.21 eV where m is an integer.

Titanium is one of the catalysts (electrocatalytic ion) that can cause resonant shrinkage because the third ionization energy is 27.49 eV, m=1 in Eq. (3). Thus, the shrinkage cascade for the pth cycle is represented by

$$27.491\text{ eV} + \mathrm{Ti}^{2+} + \mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{Ti}^{3+} + e^- + \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{51}$$

$$\mathrm{Ti}^{3+} + e^- \rightarrow \mathrm{Ti}^{2+} + 27.491\text{ eV} \tag{52}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{53}$$

Rubidium is also a catalyst (electrocatalytic ion). The second ionization energy is 27.28 eV.

$$27.28\text{ eV} + \mathrm{Rb}^{+} + \mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{Rb}^{2+} + e^- + \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{54}$$

$$\mathrm{Rb}^{2+} + e^- \rightarrow \mathrm{Rb}^{+} + 27.28\text{ eV} \tag{55}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{56}$$

Other single electron transfer reactions to provide energy holes of approximately mX27.21 eV where m is an integer appear in my previous U.S. Patent Applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989, which are incorporated herein by reference.

Multiple Electron Transfer

An energy hole is provided by the transfer of multiple electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more species to one or more species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron acceptor species equals approximately mX27.21 eV where m and t are integers.

An energy hole is provided by the transfer of multiple electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one species to another whereby the t consecutive electron affinities and/or ionization energies of the electron donating species minus the t consecutive ionization energies and/or electron affinities of the electron acceptor equals approximately mX27.21 eV where m and t are integers.

In a preferred embodiment the electron acceptor species is an oxide such as MnO_x, AlO_x, SiO_x. A preferred molecular electron acceptor is oxygen, O_2.

Two Electron Transfer (One Species)

In an embodiment, a catalytic system that provides an energy hole hinges on the ionization of two electrons from an atom, ion, or molecule to a vacuum energy level such that the sum of two ionization energies is approximately 27.21 eV. Zinc is one of the catalysts (electrocatalytic atom) that can cause resonant shrinkage because the sum of the first and second ionization energies is 27.358 eV, m=1 in Eq. (3). Thus, the shrinkage cascade for the p th cycle is represented by

$$27.358\text{ eV} + \mathrm{Zn} + \mathrm{H}\left[\frac{a_o}{p}\right] \rightarrow \mathrm{Zn}^{2+} + 2e^- + \mathrm{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{57}$$

$$\mathrm{Zn}^{2+} + 2e^- \rightarrow \mathrm{Zn} + 27.358\text{ eV} \tag{58}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{59}$$

Two Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of two electrons from an atom, ion, or molecule to another atom or molecule such that the sum of two ionization energies minus the sum of two electron affinities of the participating atoms, ions, and/or molecules is approximately 27.21 eV. A catalytic system that hinges on the transfer of two electrons from an atom to a molecule involves palladium and oxygen. For example, the first and second ionization energies of palladium are 8.34 eV and 19.43 eV, respectively. And, the first and second electron affinities of the oxygen molecule are 0.45 eV and 0.11 eV, respectively. The energy hole resulting from a two electron transfer is appropriate for resonant absorption. The combination of Pd to Pd^{2+} and O_2 to $\mathrm{O}_2^{\,2-}$, then, has a net energy change of 27.21 eV.

$$27.21\text{ eV} + \mathrm{Pd} + \mathrm{O}_2 + \mathrm{H}\left[\frac{a_o}{p}\right] \rightarrow \mathrm{Pd}^{2+} + \mathrm{O}_2^{2-} + \mathrm{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{60}$$

-continued

$$\mathrm{Pd}^{2+} + \mathrm{O}_2^{2-} \rightarrow \mathrm{Pd} + \mathrm{O}_2 + 27.21\ \mathrm{eV} \tag{61}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{62}$$

Additional atoms, molecules, or compounds which could be substituted for O_2 are those with first and second electron affinities of approximately 0.45 eV and 0.11 eV, respectively, such as a mixed oxide (MnO_x, AlO_x, SiO_x) containing O to form O^{2-} or O_2 to form O_2^{2-}.

Two Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of two electrons from an atom, ion, or molecule to another atom, ion, or molecule such that the sum of two ionization energies minus the sum of one ionization energy and one electron affinity of the participating atoms, ions, and/or molecules is approximately 27.21 eV. A catalytic system that hinges on the transfer of two electrons from an atom to an ion involves xenon and lithium. For example, the first and second ionization energies of xenon are 12.13 eV and 21.21 eV, respectively. And, the first ionization energy and the first electron affinity of lithium are 5.39 eV and 0.62 eV, respectively. The energy hole resulting from a two electron transfer is appropriate for resonant absorption. The combination of Xe to Xe^{2+} and Li^+ to Li^-, then, has a net energy change of 27.33 eV.

$$27.33\ \mathrm{eV} + \mathrm{Xe} + \mathrm{Li}^+ + \mathrm{H}\left[\frac{a_o}{p}\right] \rightarrow \mathrm{Xe}^{2+} + \mathrm{Li}^- + \mathrm{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{63}$$

$$\mathrm{Xe}^{2+} + \mathrm{Li}^- \rightarrow \mathrm{Xe} + \mathrm{Li}^+ + 27.33\ \mathrm{eV} \tag{64}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{65}$$

Two Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of two electrons from an atom, ion, or molecule to another atom, ion, or molecule such that the sum of two ionization energies minus the sum of two ionization energies of the participating atoms and/or molecules is approximately 27.21 eV. A catalytic system that hinges on the transfer of two electrons from a first ion to a second ion involves silver(Ag^+) and silver (Ag^{2+}). For example, the second and third ionization energies of silver are 21.49 eV and 34.83 eV, respectively. And, the second and first ionization energies of silver are 21.49 eV and 7.58 eV, respectively. The energy hole resulting from a two electron transfer is appropriate for resonant absorption. The combination of Ag^+ to Ag^{3+} and Ag^{2+} to Ag, then, has a net energy change of 27.25 eV.

$$27.25\ \mathrm{eV} + \mathrm{Ag}^+ + \mathrm{Ag}^{2+} + \mathrm{H}\left[\frac{a_o}{p}\right] \rightarrow \mathrm{Ag}^{3+} + \mathrm{Ag} + \mathrm{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{66}$$

$$\mathrm{Ag}^{3+} + \mathrm{Ag} \rightarrow \mathrm{Ag}^+ + \mathrm{Ag}^{2-} + 27.25\ \mathrm{eV} \tag{67}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{68}$$

Three Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of three electrons from an ion to another ion such that the sum of the electron affinity and two ionization energies of the first ion minus the sum of three ionization energies of the second ion is approximately 27.21 eV. A catalytic system that hinges on the transfer of three electrons from an ion to a second ion involves Li^- and Cr^{3+}. For example, the electron affinity, first ionization energy, and second ionization energy of lithium are 0.62 eV, 5.392 eV, and 75.638 eV, respectively. And, the third, second, and first ionization energies of Cr^{3+} are 30.96 eV, 16.50 eV, and 6.766 eV, respectively. The energy hole resulting from a three electron transfer is appropriate for resonant absorption. The combination of Li^- to Li^{2+} and Cr^{3+} to Cr, then, has a net energy change of 27.42 eV.

$$27.42\ \mathrm{eV} + \mathrm{Li}^- + \mathrm{Cr}^{3+} + \mathrm{H}\left[\frac{a_o}{p}\right] \rightarrow \mathrm{Li}^{2+} + \mathrm{Cr} + \mathrm{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{69}$$

$$\mathrm{Li}^{2+} + \mathrm{Cr} \rightarrow \mathrm{Li}^- + \mathrm{Cr}^{3+} + 27.42\ \mathrm{eV} \tag{70}$$

And, the overall reaction is

$$\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\ \mathrm{eV} \tag{71}$$

Three Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of three electrons from an atom, ion, or molecule to another atom, ion, or molecule such that the sum of three consecutive ionization energies of the electron donating species minus the sum of three consecutive ionization energies of the electron accepting species is approximately 27.21 eV. A catalytic system that hinges on the transfer of three electrons from an atom to an ion involves Ag and Ce^{3+}. For example, the first, second, and third ionization energies of silver are 7.58 eV, 21.49 eV, and 34.83 eV, respectively. And, the third, second, and first ionization energies of Ce^{3+} are 20.20 eV, 10.85 eV, and 5.47 eV, respectively. The energy hole resulting from a three electron transfer is appropriate for resonant absorption. The combination of Ag to Ag^{3+} and Ce^{3+} to Ce, then, has a net energy change of 27.38 eV.

$$27.38\text{ eV} + \text{Ag} + \text{Ce}^{3+} + \text{H}\left[\frac{a_o}{p}\right] \rightarrow \text{Ag}^{3+} + \text{Ce} + \text{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{72}$$

$$\text{Ag}^{3+} + \text{Ce} \rightarrow \text{Ag} + \text{Ce}^{3+} + 27.38\text{ eV} \tag{73}$$

And, the overall reaction is

$$\text{H}\left[\frac{a_H}{p}\right] \rightarrow \text{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{74}$$

ADDITIONAL CATALYTIC ENERGY HOLE STRUCTURES

Single Electron Transfer

In a further embodiment, an energy hole of energy equal to the total energy released for a below "ground state" electronic transition of the hydrogen atom is provided by the transfer of an electron between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of an electron from one species to another species whereby the sum of the ionization energy of the electron donating species minus the ionization energy or electron affinity of the electron accepting species equals approximately

$$\frac{m}{2}27.21\text{ eV};$$

where m is an integer.

For m=3 corresponding to the n=1 to n=½ transition, an efficient catalytic system that hinges on the coupling of three resonator cavities involves arsenic and calcium. For example, the third ionization energy of calcium is 50.908 eV. This energy hole is obviously too high for resonant absorption. However, As^+ releases 9.81 eV when it is reduced to As. The combination of Ca^{2+} to Ca^{3+} and As^+ to As, then, has a net energy change of 41.1 eV.

$$41.1\text{ eV} + \text{As}^+ + \text{Ca}^{2+} + \text{H}\left[\frac{a_o}{p}\right] \rightarrow \text{As} + \text{Ca}^{3+} + \text{H}\left[\frac{a_o}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{75}$$

$$\text{As} + \text{Ca}^{3+} \rightarrow \text{As}^+ + \text{Ca}^{2+} + 41.1\text{ eV} \tag{76}$$

And, the overall reaction is

$$\text{H}\left[\frac{a_H}{p}\right] \rightarrow \text{H}\left[\frac{a_H}{(p+1)}\right] + [(p+1)^2 - p^2] \times 13.6\text{ eV} \tag{77}$$

Multiple Electron Transfer

An energy hole is provided by the transfer of multiple electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more species to one or more species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron acceptor species equals approximately

$$\frac{m}{2}27.21\text{ eV}$$

where m and t are integers.

CATALYTIC ENERGY HOLE STRUCTURES FOR MOLECULES

Single Electron Excited State

An energy hole is provided by the transition of an electron of a species to an excited state species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the excited state transition of an electron of one species whereby the transition energy of the accepting species is mp^{2}X48.6 eV where m and p are integers.

Single Electron Transfer

An energy hole is provided by the transfer of an electron between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of an electron from one species to another species whereby the sum of the ionization energy of the electron donating species minus the ionization energy or electron affinity of the electron accepting species equals approximately mp^{2}X48.6 eV where m and p are integers.

Single Electron Transfer (Two Species)

An efficient catalytic system that hinges on the coupling of three resonator cavities involves iron and lithium. For example, the fourth ionization energy of iron is 54.8 eV. This energy hole is obviously too high for resonant absorption. However, Li^+ releases 5.392 eV when it is reduced to Li. The combination of Fe^{3+} to Fe^{4+} and Li^+ to Li, then, has a net energy change of 49.4 eV.

$$49.4\text{ eV} + \text{Fe}^{3+} + \text{Li}^+ + \text{H}_2\left[2c' = \sqrt{2}\,a_o\right] \rightarrow \text{Fe}^{4+} + \text{Li} + \text{H}_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{2}\right] + 95.7\text{ eV} \tag{78}$$

$$\text{Li} + \text{Fe}^{4+} \rightarrow \text{Li}^+ + \text{Fe}^{3+} + 49.4\text{ eV} \tag{79}$$

And, the overall reaction is

$$\text{H}_2\left[2c' = \sqrt{2}\,a_o\right] \rightarrow \text{H}_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{2}\right] + 95.7\text{ eV} \tag{80}$$

Note that the energy given off as the molecule shrinks is much greater than the energy lost to the energy hole. And, the energy released is large compared to conventional chemical reactions.

An efficient catalytic system that hinges on the coupling of three resonator cavities involves scandium. For example, the fourth ionization energy of scandium is 73.47 eV. This energy hole is obviously too high for resonant absorption. However, Sc^{3+} releases 24.76 eV when it is reduced to Sc^{2+}. The combination of Sc^{3+} to Sc^{4+} and Sc^{3+} to Sc^{2+}, then, has a net energy change of 48.7 eV.

$$48.7\text{ eV} + \text{Sc}^{3+} + \text{Sc}^{3+} + \text{H}_2\left[2c' = \sqrt{2}\,a_o\right] \rightarrow \text{Sc}^{4+} + \text{Sc}^{2+} + \text{H}_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{2}\right] + 95.7\text{ eV} \tag{81}$$

-continued

$$Sc^{2+} + Sc^{4+} \rightarrow Sc^{3+} + Sc^{3+} + 48.7 \text{ eV} \tag{82}$$

And, the overall reaction is

$$H_2[2c' = \sqrt{2}a_o] \rightarrow H_2^*\left[2c' = \frac{\sqrt{2}a_o}{2}\right] + 95.7 \text{ eV} \tag{83}$$

An efficient catalytic system that hinges on the coupling of three resonator cavities involves yttrium. For example, the fourth ionization energy of gallium is 64.00 eV. This energy hole is obviously too high for resonant absorption. However, Pb^{2+} releases 15.03 eV when it is reduced to Pb^{+}. The combination of Ga^{3+} to Ga^{4+} and Pb^{2+} to Pb^{+}, then, has a net energy change of 48.97 eV.

$$48.97 \text{ eV} + Ga^{3+} + Pb^{2+} + H_2[2c' = \sqrt{2}a_o] \rightarrow Ga^{4+} + Pb^{+} + H_2^*\left[2c' = \frac{\sqrt{2}a_o}{2}\right] + 95.7 \text{ eV} \tag{84}$$

$$Ga^{4+} + Pb^{+} \rightarrow Ga^{3+} + Pb^{2+} + 48.97 \text{ eV} \tag{85}$$

And, the overall reaction is

$$H_2[2c' = \sqrt{2}a_o] \rightarrow H_2^*\left[2c' = \frac{\sqrt{2}a_o}{2}\right] + 95.7 \text{ eV} \tag{86}$$

Single Electron Transfer (One Species)

An energy hole is provided by the ionization of an electron from a participating species including an atom, an ion, a molecule, and an ionic or molecular compound to a vacuum energy level. In one embodiment, the energy hole comprises the ionization of an electron from one species to a vacuum energy level whereby the ionization energy of the electron donating species equals approximately mp^2X48.6 eV where m and p are integers.

Multiple Electron Transfer

An energy hole is provided by the transfer of multiple electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more species to one or more species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron acceptor species equals approximately mp^2X48.6 eV where m, p, and t are integers.

An energy hole is provided by the transfer of multiple electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one species to another whereby the t consecutive electron affinities and/or ionization energies of the electron donating species minus the t consecutive ionization energies and/or electron affinities of the electron acceptor equals approximately mp^2X48.6 eV where m, p, and t are integers.

In a preferred embodiment the electron acceptor species is an oxide such as MnO_x, AlO_x, SiO_x. A preferred molecular electron acceptor is oxygen, O_2.

Two Electron Transfer (One Species)

In an embodiment, a catalytic system that provides an energy hole hinges on the ionization of two electrons from an atom, ion, or molecule to a vacuum energy level such that the sum of two ionization energies is approximately mp^2X48.6 eV where m, and p are integers.

Two Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of two electrons from an atom, ion, or molecule to another atom or molecule such that the sum of two ionization energies minus the sum of two electron affinities of the participating atoms, ions, and/or molecules is approximately mp^2X48.6 eV where m and p are integers.

Two Electron Transfer (Two Species)

In another embodiment, a catalytic system that provides an energy hole hinges on the transfer of two electrons from an atom, ion, or molecule to another atom, ion, or molecule such that the sum of two ionization energies minus the sum of one ionization energy and one electron affinity of the participating atoms, ions, and/or molecules is approximately mp^2X48.6 eV where m and p are integers.

Other Energy Holes

In another embodiment, energy holes, each of approximately mX67.8 eV given by Eq. (30)

$$-m \times V_e = -m \times \frac{-2e^2}{8\pi\varepsilon_o\sqrt{a^2-b^2}} \ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}} = m \times 67.813 \text{ eV} \tag{87}$$

are provided by electron transfer reactions of reactants including electrochemical reactant(s) (electrocatalytic ion(s) or couple(s)) which cause heat to be released from hydrogen molecules as their electrons are stimulated to relax to quantized potential energy levels below that of the "ground state". The energy removed by an electron transfer reaction, energy hole, is resonant with the hydrogen energy released to stimulate this transition. The source of hydrogen molecules is the production on the surface of a cathode during electrolysis of water in the case of an electrolytic energy reactor and hydrogen gas or a hydride in the case of a pressurized gas energy reactor or gas discharge energy reactor.

An energy hole is provided by the transfer of one or more electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more species to one or more species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron acceptor species equals approximately mX67.8 eV where m and t are integers.

An efficient catalytic system that hinges on the coupling of three resonator cavities involves magnesium and strontium. For example, the third ionization energy of magnesium is 80.143 eV. This energy hole is obviously too high for resonant absorption. However, Sr^{2+} releases 11.03 eV when it is reduced to Sr^{+}. The combination of Mg^{2+} to Mg^{3+} and Sr^{2+} to Sr^{+}, then, has a net energy change of 69.1 eV.

$$69.1 \text{ eV} + Mg^{2+} + Sr^{2+} + H_2[2c' = \sqrt{2}a_o] \rightarrow Mg^{3+} + Sr^{+} + H_2^*\left[2c' = \frac{\sqrt{2}a_o}{2}\right] + 95.7 \text{ eV} \tag{88}$$

-continued

$$Mg^{3+} + Sr^{+} \rightarrow Mg^{2+} + Sr^{2+} + 69.1 \text{ eV} \tag{89}$$

And, the overall reaction is

$$H_2\left[2c' = \sqrt{2}\, a_o\right] \rightarrow H_2^*\left[2c' = \frac{\sqrt{2}\, a_o}{2}\right] + 95.7 \text{ eV} \tag{90}$$

Another efficient catalytic system that hinges on the coupling of three resonator cavities involves magnesium and calcium. In this case, Ca^{2+} releases 11.871 eV when it is reduced to Ca^{+}. The combination of Mg^{2+} to Mg^{3+} and Ca^{2+} to Ca^{+}, then, has a net energy change of 68.2 eV.

$$68.2 \text{ eV} + Mg^{2+} + Ca^{2+} + H_2\left[2c' = \sqrt{2}\, a_o\right] \rightarrow Mg^{3+} + Ca^{+} + H_2^*\left[2c' = \frac{\sqrt{2}\, a_o}{2}\right] + 95.7 \text{ eV} \tag{91}$$

$$Mg^{3+} + Ca^{+} \rightarrow Mg^{2+} + Ca^{2+} + 68.2 \text{ eV} \tag{92}$$

And, the overall reaction is

$$H_2\left[2c' = \sqrt{2}\, a_o\right] \rightarrow H_2^*\left[2c' = \frac{\sqrt{2}\, a_o}{2}\right] + 95.7 \text{ eV} \tag{93}$$

In four other embodiments wherein the theory is given in my previous U.S. patent application Ser. No. 08/107,357 filed on Aug. 16, 1993 which is incorporated herein by this reference, energy holes, each of approximately:

nXE_T eV with zero order vibration where E_T is given by Eq. (38);

mX31.94 eV where 31.94 eV is given by Eq. (222) of the U.S. patent application Ser. No. 08/107,357 where n and m are integers,

$$\begin{aligned} E_D &= E(2H[a_o]) - E_{T_{zero\ order}} - \frac{E_{vib}}{2} \\ &= -27.21 + 31.94 = 4.73 \text{ eV} \end{aligned} \tag{222}$$

and

95.7 eV (corresponding to m=1 in Eq. (43) with zero order vibration which is given by the difference in

$$-E_{T_{zero\ order}} - \frac{E_{vib}}{2}$$

of Eqs. (254) and (222) of the U.S. patent application Ser. No. 08/107,357))

$$\begin{aligned} E_D &= E\left(2H\left[\frac{a_o}{2}\right]\right) - E_{T_{zero\ order}} - \frac{E_{vib}}{2} \\ &= -108.8 + 127.66 = 18.86 \text{ eV} \end{aligned} \tag{254}$$

are provided by electron transfer reactions of reactants including electrochemical reactant(s) (electrocatalytic ion(s) or couple(s)) which cause heat to be released from hydrogen molecules as their electrons are stimulated to relax to quantized potential energy levels below that of the "ground state". The energy removed by an electron transfer reaction, energy hole, is resonant with the hydrogen energy released to stimulate this transition. The source of hydrogen molecules is the production on the surface of a cathode during electrolysis of water in the case of an electrolytic energy reactor and hydrogen gas or a hydride in the case of a pressurized gas energy reactor or gas discharge energy reactor.

An energy hole is provided by the transfer of one or more electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more species to one or more species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron acceptor species equals approximately mX31.94 eV (Eq. (222)) where m and t are integers.

An energy hole is provided by the transfer of one or more electrons between participating species including atoms, ions, molecules, and ionic and molecular compounds. In one embodiment, the energy hole comprises the transfer of t electrons from one or more species to one or more species whereby the sum of the ionization energies and/or electron affinities of the electron donating species minus the sum of the ionization energies and/or electron affinities of the electron acceptor species equals approximately mX95.7 eV where m and t are integers.

ENERGY REACTOR

An energy reactor **50**, in accordance with the invention, is shown in FIG. **5** and comprises a vessel **52** which contains an energy reaction mixture **54**, a heat exchanger **60**, and a steam generator **62**. The heat exchanger **60** absorbs heat released by the shrinkage reaction, when the reaction mixture, comprised of shrinkable material, shrinks. The heat exchanger exchanges heat with the steam generator **62** which absorbs heat from the exchanger **60** and produces steam. The energy reactor **50** further comprises a turbine **70** which receives steam from the steam generator **62** and supplies mechanical power to a power generator **80** which converts the steam energy into electrical energy, which can be received by a load **90** to produce work or for dissipation.

The energy reaction mixture **54** comprises an energy releasing material **56** including a source of hydrogen isotope atoms or a source of molecular hydrogen isotope, and a source of energy holes **58** which resonantly remove approximately mX27.21 eV to cause atomic hydrogen "shrinkage" and approximately mX48.6 eV to cause molecular hydrogen "shrinkage" where m is an integer wherein the shrinkage reaction occurs by contact of the hydrogen with the source of energy holes. The shrinkage reaction releases heat and shrunken atoms and/or molecules.

The source of hydrogen can be hydrogen gas, dissociation of water including thermal dissociation, electrolysis of water, hydrogen from hydrides, or hydrogen from metal-hydrogen solutions. In all embodiments, the source of energy holes can be one or more of an electrochemical, chemical, photochemical, thermal, free radical, sonic, or nuclear reaction(s) or inelastic photon or particle scattering reaction(s). In the latter two cases, the present invention of an energy reactor comprises a particle source **75***b* and/or photon source **75***a* to supply the said energy holes. In these cases, the energy hole corresponds to stimulated emission by the photon or particle. In preferred embodiments of the pressurized gas energy and gas discharge reactors shown in FIGS. **7** and **8**, respectively, a photon source **75***a* dissociates hydrogen molecules to hydrogen atoms. The photon source producing photons of at least one energy of approximately mX27.21 eV,

$$\frac{m}{2}\times 27.21\ \text{eV},$$

or 40.8 eV causes stimulated emission of energy as the hydrogen atoms undergo the shrinkage reaction. In another preferred embodiment, a photon source **75***a* producing photons of at least one energy of approximately mX48.6 eV, 95.7 eV, or mX31.94 eV causes stimulated emission of energy as the hydrogen molecules undergo the shrinkage reaction. In all reaction mixtures, a selected external energy device **75**, such as an electrode may be used to supply an electrostatic potential or a current (magnetic field) to decrease the activation energy of the resonant absorption of an energy hole. In another embodiment, the mixture **54**, further comprises a surface or material to dissociate and/or absorb atoms and/or molecules of the energy releasing material **56**. Such surfaces or materials to dissociate and/or absorb hydrogen, deuterium, or tritium comprise an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite). In a preferred embodiment, a source of energy holes to shrink hydrogen atoms comprises a catalytic energy hole material **58**, typically comprising electrocatalytic ions and couples that provide an energy hole of approximately mX27.21 eV plus or minus 1 eV. In a preferred embodiment, a source of energy holes to shrink hydrogen molecules comprises a catalytic energy hole material **58**, typically comprising electrocatalytic ions and couple (s) including those that provide an energy hole of approximately nX48.6 eV plus or minus 5 eV. The electrocatalytic ions and couple(s) include the electrocatalytic ions and couples described in my previous U.S. Patent Applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/1626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989, which are incorporated herein by reference.

A further embodiment is the vessel **52** containing a source of energy holes including an electrocatalytic ion or couple(s) (source of energy holes) in the molten, liquid, gaseous, or solid state and a source of hydrogen including hydrides and gaseous hydrogen. In the case of a reactor which shrinks hydrogen atoms, the embodiment further comprises a means to dissociate the molecular hydrogen into atomic hydrogen including an element, compound, alloy, or mixture of transition elements, inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite) or electromagnetic radiation including UV light provided by photon source **75**.

The present invention of an electrolytic cell energy reactor, pressurized gas energy reactor, and a gas discharge energy reactor, comprises: a source of hydrogen; one of a solid, molten, liquid, and gaseous source of energy holes; a vessel containing hydrogen and the source of energy holes wherein the shrinkage reaction occurs by contact of the hydrogen with the source of energy holes; and a means for removing the (molecular) lower-energy hydrogen so as to prevent an exothermic shrinkage reaction from coming to equilibrium. The present energy invention is further described in my previous U.S. Patent Applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989, and my publications, Mills, R., Kneizys, S., Fusion Technology, 210, (1991), pp. 65–81; Mills, R., Good, W., Shaubach, R., "Dihydrino Molecule Identification", Fusion Technology, 25, 103 (1994); Mills, R., Good, W., "Fractional Quantum Energy Levels of Hydrogen", Fusion Technology, Vol. 28, No. 4, November, (1995), pp. 1697–1719 which are incorporated herein by reference.

Electrolytic Energy Reactor

An electrolytic energy reactor is described in my previous U.S. patent applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989 which are incorporated herein by reference. A preferred embodiment of the energy reactor of the present invention comprises an electrolytic cell forming the reaction vessel **52** of FIG. **5** including a molten electrolytic cell. The electrolytic cell **100** is shown generally in FIG. **6**. An electric current is passed through the electrolytic solution **102** having a electrocatalytic ions or couples providing energy holes equal to the resonance shrinkage energy (including the electrocatalytic ions and couples described in my previous U.S. Patent Applications incorporated herein by reference) by the application of a voltage to an anode **104** and cathode **106** by the power controller **108** powered by the power supply **110**. Ultrasonic or mechanical energy may also be imparted to the cathode **106** and electrolytic solution **102** by vibrating means **112**. Heat can be supplied to the electrolytic solution **102** by heater **114**. The pressure of the electrolytic cell **100** can be controlled by pressure regulator means **116** where the cell can be closed. The reactor further comprises a means **101** that removes the (molecular) lower-energy hydrogen such as a selective venting valve to prevent the exothermic shrinkage reaction from coming to equilibrium.

In a preferred embodiment, the electrolytic cell is operated at zero voltage gap by applying an overpressure of hydrogen with hydrogen source **121** where the overpressure can be controlled by pressure control means **122** and **116**. Water can be reduced to hydrogen and hydroxide at the cathode **106**, and the hydrogen can be oxidized to protons at the anode **104**. An embodiment of the electrolytic cell energy reactor, comprises a reverse fuel cell geometry which removes the lower-energy hydrogen under vacuum. A preferred cathode **106** of this embodiment has a modified gas diffusion layer and comprises a gas route means including a first Teflon membrane filter and a second carbon paper/Teflon membrane filter composite layer. A further embodiment comprises a reaction vessel that can be closed except for a connection to a condensor **140** on the top of the vessel **100**. The cell can be operated at a boil such that the steam evolving from the boiling electrolyte **102** can be condensed in the condenser **140**, and the condensed water can be returned to the vessel **100**. The lower-energy state hydrogen can be vented through the top of the condenser **140**. In one embodiment, the condensor contains a hydrogen/oxygen recombiner **145** that contacts the evolving electrolytic gases. The hydrogen and oxygen are recombined, and the resulting water can be returned to the vessel **100**. The heat released from the exothermic reaction whereby the electrons of the electrolytically produced hydrogen atoms (molecules) are induced to undergo transitions to energy levels below the "ground state" and the heat released due to the recombination of the electrolytically generated normal hydrogen and oxygen can be removed by a heat exchanger **60** of FIG. **5** which can be connected to the condensor **140**.

In vacuum, in the absence of external fields, the energy hole to stimulate a hydrogen atom (molecule) to undergo a shrinkage transition is mX27.21 eV (mX48.6 eV) where m is an integer. This resonance shrinkage energy can be altered when the atom (molecule) is in a media different from vacuum. An example is a hydrogen atom (molecule) absorbed to the cathode **106** present in the aqueous electrolytic solution **102** having an applied electric field and an intrinsic or applied magnetic field provided by external magnetic field generator **75**. Under these conditions the energy hole required can be slightly different from mX27.21 eV (mX48.6 eV). Thus, a source of energy holes including electrocatalytic ion and couple reactants can be selected which has a redox (electron transfer) energy resonant with the resonance shrinkage energy when operating under these conditions. In the case where a nickel cathode **106** is used to electrolyze an aqueous solution **102** where the cell is operating within a voltage range of 1.4 to 5 volts, the K^+/K^+ and Rb^+ (Fe^{3+}/Li^+ and Sc^{3+}/Sc^{3+}) electrocatalytic ions and couples are preferred embodiments to shrink hydrogen atoms (molecules).

The cathode provides hydrogen atoms (molecules), and the shrinkage reaction occurs at the surface of the cathode where hydrogen atoms (molecules) and the source of energy holes (electrocatalytic ion or couple) are in contact. Thus, the shrinkage reaction can be dependent on the surface area of the cathode. For a constant current density, giving a constant concentration of hydrogen atoms (molecules) per unit area, an increase in surface area increases the reactants available to undergo the shrinkage reaction. Also. an increase in cathode surface area decreases the resistance of the electrolytic cell which improves the electrolysis efficiency. A preferred cathode of the electrolytic cell including a nickel cathode has the properties of a high surface area, a highly stressed and hardened surface such as a cold drawn or cold worked surface, and a large number of grain boundaries.

In a preferred embodiment of the electrolytic cell energy reactor, the source of energy holes can be incorporated into the cathode, mechanically by methods including cold working the source of energy holes into the surface of the cathode; thermally by methods including melting the source of energy holes into the surface of the cathode and evaporation of a solvent of a solution of the source of energy holes in contact with the surface of the cathode, and electrostatically by methods including electrolytic deposition, ion bombardment, and vacuum deposition.

The shrinkage reaction rate can be dependent upon the composition of the cathode **106**. Hydrogen atoms (molecules) are reactants to produce energy via the shrinkage reaction. Thus, the cathode must efficiently provide a high concentration of hydrogen atoms (molecules). The cathode **106** can be comprised of any element. compound, alloy, or mixture of a conductor or semiconductor including transition elements and compounds, actinide and lanthanide elements and compounds, and group IIIB and IVB elements and compounds. Transition metals dissociate hydrogen gas into atoms to a more or lesser extent depending on the metal. Nickel and titanium readily dissociate hydrogen molecules and are preferred embodiments for shrinking hydrogen atoms. The cathode can alter the energy of the absorbed hydrogen atoms (molecules) and affect the energy of the shrinkage reaction. A cathode material can be selected which provides resonance between the energy hole and the resonance shrinkage energy. In the case of the K^+/K^+ electrocatalytic couple with carbonate as the counterion for catalyzing the shrinkage of hydrogen atoms, the relationship of the cathode material to the reaction rate can be:

$$Pt<Pd<<Ti,Fe<Ni$$

This can be the opposite order of the energy released when these materials absorb hydrogen atoms. Thus, for this electrocatalytic couple, the reaction rate can be increased by using a cathode which weakly absorbs the hydrogen atoms with little perturbation of their electronic energies.

Also, coupling of resonator cavities and enhancement of the transfer of energy between them can be increased when the media is a nonlinear media such as a magnetized ferromagnetic media. Thus, a paramagnetic or ferromagnetic cathode, a nonlinear magnetized media, increases the reaction rate by increasing the coupling of the resonance shrinkage energy of the hydrogen atom and energy hole comprising an electrocatalytic ion or couple. Alternatively, a magnetic field can be applied with the magnetic field generator **75**. Magnetic fields at the cathode alter the energy of absorbed hydrogen and concomitantly alter the resonance shrinkage energy. Magnetic fields also perturb the energy of the electrocatalytic reactions (energy hole) by altering the energy levels of the electrons involved in the reactions. The magnetic properties of the cathode are selected as well as the strength of the magnetic field which is applied by magnetic field generator **75** to optimize shrinkage reaction rate-the power output. A preferred ferromagnetic cathode is nickel.

A preferred method to clean the cathode of the electrolytic cell including a nickel cathode is to anodize the cathode in a basic electrolytic solution including approximately 0.57 M X_2CO_3 (X is the alkali cation of the electrolyte including K^+) and to immerse the cathode in a dilute solution of H_2O_2 such as approximately 3% H_2O_2. In a further embodiment of the cleaning method, cyclic voltametry with a second electrode of the same material as the first cathode is performed. The cathode can be then thoroughly rinsed with distilled water. Organic material on the surface of the cathode inhibits the catalytic reaction whereby the electrons of the electrolytically produced hydrogen atoms (molecules) are induced to undergo transitions to energy levels below the "ground state". Cleaning by this method removes the organic material from the cathode surface and adds oxygen atoms onto the cathode surface. Doping the metal surface, including a nickel surface, with oxygen atoms by anodizing the cathode and cleaning the cathode in H_2O_2 increases the power output by decreasing hydrogen recombination to molecular hydrogen and by decreasing the bond energy between the metal and the hydrogen atoms (molecules) which conforms the resonance shrinkage energy of the absorbed hydrogen to the energy hole provided by the source of energy holes including the K^+/K^+ (Sc^{3+}/Sc^{3+}) electrocatalytic couples.

Different anode materials have different overpotentials for the oxidation of water, which can affect ohmic losses. An anode of low overpotential will increase the efficiency. Nickel, platinum, and dimensionally stable anodes including platinized titanium are preferred anodes. In the case of the K^+/K^+ electrocatalytic couple where carbonate is used as the counterion, nickel is a preferred anode. Nickel is also a preferred anode for use in basic solutions with a nickel cathode. Nickel is inexpensive relative to platinum, and fresh nickel can be electroplated onto the cathode during electrolysis.

A preferred method to clean a dimensionally stable anode including a platinized titanium anode is to place the anode in approximately 3 M HCl for approximately 5 minutes and then to rinse it with distilled water.

In the case of hydrogen atom shrinkage, hydrogen atoms at the surface of the cathode **106** form hydrogen gas which can form bubbles on the surface of the cathode. These bubbles act as an boundary layer between the hydrogen atoms and the electrocatalytic ion or couple. The boundary can be ameliorated by vibrating the cathode and/or the electrolytic solution **102** or by applying ultrasound with vibrating means **112**; and by adding wetting agents to the electrolytic solution **102** to reduce the surface tension of the water and prevent bubble formation. The use of a cathode having a smooth surface or a wire cathode prevents gas adherence. And an intermittent current, provided by an on-off circuit of power controller **108** provides periodic replenishing of hydrogen atoms which are dissipated by hydrogen gas formation followed by diffusion into the solution while preventing excessive hydrogen gas formation which could form a boundary layer.

The shrinkage reaction can be temperature dependent. Most chemical reactions double their rates for each 10° C. rise in temperature. Increasing the temperature increases the collision rate between the hydrogen atoms (molecules) and the electrocatalytic ion or couple which will increase the shrinkage reaction rate. With large temperature excursions from room temperature, the kinetic energy distribution of the reactants can be sufficiently altered to cause the energy hole and the resonance shrinkage energy to conform to a more or lesser extent. The rate can be proportional to the extent of the conformation or resonance of these energies. The temperature can be adjusted to optimize the shrinkage reaction rate-energy production rate. In the case of the K^+/K^+ electrocatalytic couple, a preferred embodiment can be to run the reaction at a temperature above room temperature by applying heat with heater **114**.

The shrinkage reaction can be dependent on the current density. An increase in current density can be equivalent, in some aspects, to an increase in temperature. The collision rate increases, and the energy of the reactants increases with current density. Thus, the rate can be increased by increasing the collision rate of the reactants; however, the rate may be increased or decreased depending on the effect of the increased reactant energies on the conformation of the energy hole and the resonance shrinkage energy. Also, increased current dissipates more energy by ohmic heating and may cause hydrogen bubble formation, in the case of the shrinkage of hydrogen atoms. But, a high flow of gas may dislodge bubbles which diminishes any hydrogen gas boundary layer. The current density can be adjusted with power controller **108** to optimize the excess energy production. In a preferred embodiment, the current density can be in the range 1 to 1000 milliamps per square centimeter.

The pH of the aqueous electrolytic solution **102** can affect the shrinkage reaction rate. In the case that the electrocatalytic ion or couple is positively charged, an increase in the pH will reduce the concentration of hydronium at the negative cathode; thus, the concentration of the electrocatalytic ion or couple cations will increase. An increase in reactant concentration increases the reaction rate. In the case of the Rb^+ or K^+/K^+ (Sc^{3+}/Sc^{3+}) ion or couple, a preferred pH can be basic (7.1–14).

The counterion of the electrocatalytic ion or couple of the electrolytic solution **102** can affect the shrinkage reaction rate by altering the energy of the transition state. For example, the transition state complex of the K^+/K^+ electrocatalytic couple with the hydrogen atom has a plus two charge and involves a three body collision which can be unfavorable. A negative two charged oxyanion can bind the two potassium ions; thus, it provides a neutral transition state complex of lower energy whose formation depends on a binary collision which can be greatly favored. The rate can be dependent on the separation distance of the potassium ions as part of the complex with the oxyanion. The greater the separation distance, the less favorable can be the transfer of an electron between them. A close juxtaposition of the potassium ions will increase the rate. The relationship of the reaction rate to the counterion in the case where the K^+/K^+ couple is used can be:

$$OH^{-}<PO_4^{3-},\ HPO_3^{2-}<SO_4^{2-}<<CO_3^{2-}$$

Thus, a planar negative two charge oxyanion including carbonate with at least two binding sites for K^+ which provides close juxtaposition of the K^+ ions can be preferred as the counterion of the K^+/K^+ electrocatalytic couple. The carbonate counterion can be also a preferred counterion for the Rb^+ electrocatalytic ion.

A power controller **108** comprising an intermittent current, on-off, electrolysis circuit will increase the excess heat by providing optimization of the electric field as a function of time which provides maximum conformation of reactant energies, provides an optimal concentration of hydrogen atoms (molecules) while minimizing ohmic and electrolysis power losses and, in the case of the shrinkage of hydrogen atoms, minimizes the formation of a hydrogen gas boundary layer. The frequency, duty cycle, peak voltage, step waveform, peak current, and offset voltage are adjusted to achieve the optimal shrinkage reaction rate and shrinkage reaction power while minimizing ohmic and electrolysis power losses. In the case where the K^+/K^+ electrocatalytic couple can be used with carbonate as the counterion; nickel as the cathode: and platinum as the anode, a preferred embodiment can be to use an intermittent square-wave having an offset voltage of approximately 1.4 volts to 2.2 volts; a peak voltage of approximately 1.5 volts to 3.75 volts; a peak current of approximately 1 mA to 100 mA per square centimeter of cathode surface area; approximately a 5%–90% duty cycle; and a frequency in the range of 1 Hz to 1500 Hz.

Further energy can be released by repeating the shrinkage reaction. The atoms (molecules) which have undergone shrinkage diffuse into the cathode lattice. A cathode **106** can be used which will facilitates multiple shrinkage reactions of hydrogen atoms (molecules). One embodiment is to use a cathode which can be fissured and porous to the electrocatalytic ion or couple such that it can contact shrunken atoms (molecules) which have diffused into a lattice, including a metal lattice. A further embodiment is to use a cathode of alternating layers of a material which provides hydrogen atoms (molecules) during electrolysis including a transition metal and an electrocatalytic ion or couple such that shrunken hydrogen atoms (molecules) periodically or repetitively diffuse into contact with the electrocatalytic ion or couple.

The shrinkage reaction can be dependent on the dielectric constant of the media. The dielectric constant of the media alters the electric field at the cathode and concomitantly alters the energy of the reactants. Solvents of different dielectric constants have different solvation energies, and the dielectric constant of the solvent can also lower the overpotential for electrolysis and improve electrolysis efficiency. A solvent, including water, can be selected for the electrolytic solution **102** which optimizes the conformation of the energy hole and resonance shrinkage energy and maximizes the efficiency of electrolysis.

The solubility of hydrogen in the reaction solution can be directly proportional to the pressure of hydrogen above the solution. Increasing the pressure increases the concentration of reactant hydrogen atoms (molecules) at the cathode **106** and thereby increases the rate. But, in the case of the shrinkage of hydrogen atoms this also favors the development of a hydrogen gas boundary layer. The hydrogen pressure can be controlled by pressure regulator means **116** to optimize the shrinkage reaction rate.

In a preferred embodiment, the cathode **106** of the electrolytic cell comprises the catalytic material including a hydrogen spillover catalyst described in the Pressurized Gas Energy Reactor Section below. In another embodiment, the cathode comprises multiple hollow vessels comprising a thin film conductive shell whereby lower-energy hydrogen diffuses through the thin film and collects inside each vessel and undergoes disproportionation reactions therein.

The heat output can be monitored with thermocouples present in at least the vessel **100** and the condensor **140** of FIG. **6** and the heat exchanger **60** of FIG. **5**. The output power can be controlled by a computerized monitoring and control system which monitors the thermistors and controls the means to alter the power output.

Pressurized Gas Energy Reactor

A pressurized gas energy reactor comprises the first vessel **200** of FIG. **7** containing a source of hydrogen including hydrogen from metal-hydrogen solutions, hydrogen from hydrides, hydrogen from the dissociation of water including thermal dissociation, hydrogen from the electrolysis of water, or hydrogen gas. In the case of a reactor which shrinks hydrogen atoms, the reactor further comprises a means to dissociate the molecular hydrogen into atomic hydrogen such as a dissociating material including an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite) or electromagnetic radiation including UV light provided by photon source **205** such that the dissociated hydrogen atoms (molecules) contact a source of energy holes including a molten, liquid, gaseous, or solid source of the energy holes including the electrocatalytic ions and couples described in my previous U.S. Patent Applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989, which are incorporated herein by reference. The pressurized gas energy reactor further comprises a means **201** to remove the (molecular) lower-energy hydrogen such as a selective venting valve to prevent the exothermic shrinkage reaction from coming to equilibrium. One embodiment comprises heat pipes as heat exchanger **60** of FIG. **5** which have a lower-energy hydrogen venting valve at a cold spot.

A preferred embodiment of the pressurized gas energy reactor of the present invention comprises a first reaction vessel **200** with inner surface **240** comprised of a material to dissociate the molecular hydrogen into atomic hydrogen including an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Th, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite). In a further embodiment, the inner surface **240** can be comprised of a proton conductor. The first reaction vessel **200** can be sealed in a second reaction vessel **220** and receives hydrogen from source **221** under pressure which can be controlled by pressure measurement and control means **222** and **223**. In a preferred embodiment the hydrogen pressure can be in the range of 10^{-3} atmospheres to **100** atmospheres. The wall **250** of the first vessel **200** can be permeable to hydrogen. The outer surface **245** and/or outer vessel **220** has a source of energy holes equal to the resonance shrinkage energy. In one embodiment the source of energy holes can be a mixture or solution containing energy holes in the molten, liquid, or solid state. In another embodiment an electric current can be passed through the material having a source of energy holes. The reactor further comprises a means to control the reaction rate such as current source **225** and heating means **230** which heat the first reaction vessel **200** and the second reaction vessel **220**. In a preferred embodiment the outer reaction vessel **220** contains oxygen, the inner surface **240** comprises one or more of a coat of nickel, platinum, or palladium. The outer surface **245** can be coated with one or more of copper, tellurium, arsenic, cesium, platinum, or palladium and an oxide such as CuO_x, PtO_x, PdO_x, MnO_x, AlO_x, SiO_x. The electrocatalytic ion or couple can be regenerated spontaneously or via a regeneration means including heating means **230** and current source **225**.

In another embodiment, the pressurized gas energy reactor comprises only a single reaction vessel **200** with a hydrogen impermeable wall **250**. In the case of a reactor which shrinks hydrogen atoms, one or more of a hydrogen dissociating materials including transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite) are coated on the inner surface **240** with a source of energy holes including one or more of copper, tellurium, arsenic, cesium, platinum, or palladium and an oxide such as CuO_x, PtO_x, PdO_x, MnO_x, AlO_x, SiO_x. In another embodiment, the source of energy hole can be one of a inelastic photon or particle scattering reaction(s). In a preferred embodiment the photon source **205** supplies the energy holes where the energy hole corresponds to stimulated emission by the photon. In the case of a reactor which shrinks hydrogen atoms the photon source **205** dissociates hydrogen molecules into hydrogen atoms. The photon source producing photons of at least one energy of approximately mX27.21 eV,

$$\frac{m}{2} \times 27.21 \text{ eV},$$

or 40.8 eV causes stimulated emission of energy as the hydrogen atoms undergo the shrinkage reaction. In another preferred embodiment, a photon source **205** producing photons of at least one energy of approximately mX48.6 eV, 95.7 eV, or mX31.94 eV causes stimulated emission of energy as the hydrogen molecules undergo the shrinkage reaction.

A preferred inner surface, **240**, and outer surface, **245**, of the pressurized gas energy reactor including a nickel surface has the properties of a high surface area, a highly stressed and hardened surface such as a cold drawn or cold worked surface, and a large number of grain boundaries.

In an embodiment of the pressurized gas energy reactor, the source of energy holes can be incorporated into the inner surface, **240**, and outer surface, **245**, mechanically by methods including cold working the source of energy holes into the surface material and thermally by methods including melting the source of energy holes into the surface material (fusion). Further methods of incorporation include dry impregnation, evaporation of a solution of the source of energy holes in contact with the surface material (precipitation), ion bombardment, vacuum deposition, impregnation, leaching, and electrostatic incorporation including electrolytic deposition and electroplating. A preferred method to clean the inner surface **240** and the outer surface **245** including a nickel surface is to fill the inner vessel and the outer vessel with a basic electrolytic solution including approximately 0.57 M X_2CO_3 (X is the alkali cation of the electrolyte including K^+) and to fill the inner vessel and the outer vessel with a dilute solution of H_2O_2. Each of the inner vessel and the outer vessel can be then thoroughly rinsed with distilled water. In one embodiment, at least one of the vessel **200** or the vessel **220** can be then filled with a solution of the energy hole including an approximately 0.57 M K_2CO_3 solution.

In a further embodiment, textural and/or structural promoters are incorporated with the source of energy holes to increase the shrinkage reaction rate.

In one embodiment of the method of operation of the pressurized gas energy reactor, hydrogen can be introduced inside of the first vessel from source **221** under pressure which can be controlled by pressure control means **222**. In the case of a reactor which shrinks hydrogen atoms, the molecular hydrogen can be dissociated into atomic hydrogen by a dissociating material or electromagnetic radiation including UV light provided by photon source **205** such that the dissociated hydrogen atoms contact a source of energy holes including a molten, liquid, gaseous, or solid source of the energy holes. The atomic (molecular) hydrogen releases energy as its electrons are stimulated to undergo transitions to lower energy levels by the energy holes. Alternatively, the hydrogen dissociates on the inner surface **240**, diffuses though the wall **250** of the first vessel **200** and contacts a source of energy holes on the outer surface **245** or contact a source of energy holes including a molten, liquid, gaseous, or solid source of the energy holes as hydrogen atoms or recombined hydrogen molecules. The atomic (molecular) hydrogen releases energy as its electrons are stimulated to undergo transitions to lower energy levels by the energy holes. The electrocatalytic ion or couple can be regenerated spontaneously or via a regeneration means including heating means **230** and current source **225**. The (molecular) lower-energy hydrogen can be removed from vessel **200** and/or vessel **220** by a means to remove the (molecular) lower-energy hydrogen such as a selective venting valve means **201** which prevents the exothermic shrinkage reaction from coming to equilibrium. To control the reaction rate (the power output), an electric current can be passed through the material having a source of energy holes equal to the resonance shrinkage energy with current source **225**, and/or the first reaction vessel **200** and the second reaction vessel **220** are heated by heating means **230**. The heat output can be monitored with thermocouples present in at least the first vessel **200**, the second vessel **220**, and the heat exchanger **60** of FIG. **5**. The output power can be controlled by a computerized monitoring and control system which monitors the thermistors and controls the means to alter the power output. The (molecular) lower-energy hydrogen can be removed by a means **201** to prevent the exothermic shrinkage reaction from coming to equilibrium.

A method of preparation of the catalytic material of the present invention of catalytic systems that hinge on the transfer of an electron from a cation to another capable of producing energy holes for shrinking hydrogen atoms includes the steps of:

Mixing the oxides of the cations with the hydrogen dissociating material.

Thoroughly mixing by repeatedly sintering and pulverizing.

Example of a Ceramic Catalytic Material: Strontium Niobium Oxide ($SrNb_2O_6$) on Ni Powder

To prepare the ceramic catalytic material: strontium niobium oxide ($SrNb_2O_6$) on Ni powder, 2.5 kg of $SrNb_2O_6$ are added to 1.5 kg of −300 mesh Ni powder. The materials are mixed to make a homogeneous mixture. The powder can be sintered or calcinated in an oven at 1600° C. in atmospheric air for 24 hours. The material can be cooled and ground to remove lumps. The material can be re-sintered at 1600° C. in air for another 24 hours. The material can be cooled to room temperature and powderized.

A method of preparation of the catalytic material of the present invention of catalytic systems that hinge on the transfer of an electron from a cation to another capable of producing energy holes for shrinking hydrogen atoms includes the steps of:

Dissolving ionic salts of the cations into a solvent. In a preferred embodiment, the ionic salts are dissolved in deionized demineralized water to concentration of 0.3 to 0.5 molar.

Uniformly wetting a dissociation material with the dissolved salt solution.

Draining the excess solution.

Drying the wetted dissociation material in an oven preferably at a temperature of 220° C.

Pulverizing the dried catalytic material into a powder.

Example of a Ionic Catalytic Material: Potassium Carbonate (K_2CO_3) on Ni Powder

To prepare the ionic catalytic material: potassium carbonate (K_2CO_3) on Ni powder, a 1 liter solution of 0.5 M K_2CO_3

in water is poured over 500 grams of −300 mesh Ni powder. The materials are stirred to remove air pockets around the grains of Ni. The excess solution can be drained off. The powder can be dried in an oven at 200° C. If necessary the material can be ground to remove lumps.

Hydrogen Spillover Catalysts

In a preferred embodiment, the source of hydrogen atoms for the catalytic shrinkage reaction comprises a hydrogen spillover catalyst.

A hydrogen spillover catalyst according to the present invention comprises:

A hydrogen dissociation material or means which forms free hydrogen atoms or protons;

A conduit material onto which free hydrogen atoms spill and which supports free, mobile hydrogen atoms and provides a path or conduit for the flow of hydrogen atoms or protons;

A source of energy holes which catalyze the shrinkage reaction, and optionally

A support material into which the former materials are embedded as a mixture, compound, or solution.

Such hydrogen dissociation materials include surfaces or materials to dissociate hydrogen, deuterium, or tritium, comprise an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite). Such conduit materials onto which free hydrogen atoms spill and which supports free, mobile hydrogen atoms and which provides a path or conduit for the flow of hydrogen atoms include nickel, platinum, carbon, tin, iron, aluminum, and copper and their compounds, mixtures, or alloys. In an embodiment, such support materials into which the former materials are embedded as a mixture, compound, or solution includes carbon, silica, nickel, copper, titania, zinc oxide, chromia, magnesia, zirconia, alumina, silica-alumina, and zeolites. In an embodiment, one or more of the other components are deposited on the support material by electroplating. The source of energy holes to cause atomic hydrogen "shrinkage" are preferably of approximately mX27.21 eV and/or to cause molecular hydrogen "shrinkage" are of approximately mX48.6eV where m is an integer including the electrocatalytic ions and couples described in my previous U.S. Patent Applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989, which are incorporated herein by reference. The counterion of the energy hole of the spillover catalyst includes those given in the Handbook of Chemistry and Physics, Robert C. Weast, Editor, 58th Edition, CRC Press, West Palm Beach, Fla., (1974) pp. B61–B178 which is incorporated by reference herein, organic ions including benzoic acid, phthalate, salicylate, aryl sulfonate, alky sulfate, alkyl sulfonate, and alkyl carboxylate, and the anion of an acid which forms an acid anhydride including sulfite, sulfate, carbonate, bicarbonate, nitrite, nitrate, perchlorate, phosphite, hydrogen phosphite, dihydrogen phosphite, phosphate, hydrogen phosphate, and dihydrogen phosphate. In another embodiment the anion can be in equilibrium with its acid and its acid anhydride.

The functionalities of the hydrogen spillover catalyst are combined with the other functionalities as separate species or as combinations comprising a mixture, solution, compound, or alloy of more than one functionality. For example, in one embodiment, the hydrogen dissociation material and the source of energy holes each comprise homogeneous crystals— each crystal contains one component. and these functionalities are mixed with the conduit material without a support material. Whereas, in another embodiment, the hydrogen dissociation material and the source of energy holes comprise heterogeneous crystals-each crystal contains both of the components, and the heterogeneous crystals are mixed with the conduit material which coats a support material. In a third exemplary embodiment, the source of energy holes can be embedded in the conduit material. and this combined species can be mixed with the hydrogen dissociation material which can be embedded in the same or a different conduit material without a support material.

A method of preparation of the hydrogen spillover catalytic material of the present invention includes the steps of:

Mixing the components of the spillover catalyst by the method of incipient wetness impregnation.

Thoroughly mixing the components by sintering.

A further method of preparation of the hydrogen spillover catalytic material of the present invention includes the steps of:

Dissolving or dispersing the components to be mixed in a suitable solvent such as water and drying the solution or mixture.

Removing the solvent by drying, or the wet mixture, suspension, or solution can be frozen and the solvent can be sublimed.

Thoroughly mixing the components by sintering.

An incipient wetness method of preparation of the hydrogen spillover catalytic material of the present invention comprising a source of energy holes for shrinking hydrogen atoms that hinge on the transfer of an electron from a cation to another includes the steps of:

Dissolving a desired weight of the ionic salts of the cations into a desired volume of solvent. In a preferred embodiment, the ionic salts are dissolved in deionized demineralized water.

Preparing an incipiently wet conduit-hydrogen dissociation material by uniformly wetting the conduit-hydrogen dissociation material with the dissolved salt solution so that the pores of the material are just filled. The total volume of solvent required can be the desired amount, and the weight percent of the ionic salts of the cations in the final material can be determined by the desired weight of the ionic salts of the cations dissolved in the desired volume of solvent.

Mechanically mixing the wetted material to insure uniform wetting.

Drying the incipiently wet conduit-hydrogen dissociation material in an oven preferably at a temperature of 150° C. In an embodiment the material can be heated until the counterion(s) of the cations chemically decompose to preferably oxides.

Pulverizing the dried material comprised of the conduit-hydrogen dissociation-source of energy holes material into a powder.

- Optionally, mechanically mixing the dried and powdered material with further hydrogen dissociation material including a powder mixed with a conduit material and a support material.

Example of a Ionic Hydrogen Spillover Catalytic Material: 40% by Weight Potassium Nitrate (KNO_3) on 1%-Pd-on-Graphitic Carbon Powder

To prepare one kilogram of the ionic hydrogen spillover catalytic material: 40% by weight potassium nitrate (KNO_3) on 1%-Pd-on-graphitic carbon powder, 0.40 kg of KNO_3 are dissolved in 1 liter of H_2O. Incipient wetness requires 1 ml of H_2O per gram of −300 mesh graphite powder, and 0.67 grams of KNO_3 are required per gram of graphitic carbon powder to achieve a 40% by weight KNO_3 content in the final material. The aqueous KNO_3 solution can be slowly added to 0.6 kg of 1%-Pd-on-300-mesh-graphitic carbon powder as the slurry can be mixed. The slurry can be then placed on an evaporation dish which can be inserted into an oven at 150° C. for one hour. Heating causes the water to evaporate from the slurry. The KNO_3 coated 1%-Pd-on-graphitic carbon can be ground into a powder.

Another incipient wetness method of preparation of the hydrogen spillover catalytic material of the present invention comprising a source of energy holes for shrinking hydrogen atoms that hinge on the transfer of an electron from a cation to another includes the steps of:

- Dissolving a desired weight of the ionic salts of the cations into a desired volume of solvent. In a preferred embodiment, the ionic salts are dissolved in deionized demineralized water.
- Preparing an incipiently wet conduit material by uniformly wetting the conduit material with the dissolved salt solution so that the pores of the material are just filled. The total volume of solvent required can be the desired amount, and the weight percent of the ionic salts of the cations in the final material can be determined by the desired weight of the ionic salts of the cations dissolved in the desired volume of solvent.
- Mechanically mixing the wetted material to insure uniform wetting.
- Drying the incipiently wet conduit material in an oven preferably at a temperature of 150° C. In an embodiment, the material can be heated until the counterion(s) of the cations chemically decompose to preferably oxides.
- Pulverizing the dried material comprised of the conduit material and the source of energy holes into a powder.
- Mechanically mixing the dried and powdered material with a hydrogen dissociation material including a powder mixed with a conduit material and a support material.

Example of a Ionic Hydrogen Spillover Catalytic Material: 40% by Weight Potassium Nitrate (KNO_3) on Graphitic Carbon Powder with 5% by Weight 1%-Pd-on-Graphitic Carbon Powder

To prepare one kilogram of the ionic hydrogen spillover catalytic material: 40% by weight potassium nitrate (KNO_3) on graphitic carbon powder with 5% by weight 1%-Pd-on-graphitic carbon powder, 0.67 kg of KNO_3 are dissolved in 1 liter of H_2O. Incipient wetness requires 1 ml of H_2O per gram of −300 mesh graphite powder, and 0.40 grams of KNO_3 are required per gram of graphite powder to achieve a 40% by weight KNO_3 content in the final material. The aqueous KNO_3 solution can be slowly added to 0.55 kg of graphite powder as the slurry can be mixed. The slurry can be then placed on an evaporation dish which can be inserted into an oven at 150° C. for one hour. Heating causes the water to evaporate from the slurry. The KNO_3 coated graphite can be ground into a powder. The powder can be weighed. Approximately 50 grams (5% of the weight of the KNO_3 coated graphite) of 1%-Pd-on--300-mesh graphitic carbon powder can be mixed into the KNO_3 coated graphitic carbon powder.

Example of the Mode of Operation of the Exemplary Catalytic Materials

The catalytic material can be placed into the pressurizable vessel **200**. The vessel can be flushed with an inert gas such as He, Ar, or Ne to remove air contaminants in the vessel. The vessel and its contents are heated to the operational temperature, typically 100° C. to 400° C., before the vessel can be pressurized with hydrogen, typically 20 to 140 PSIG.

In an embodiment, the source of energy holes is potassium ions (K^+/K^+) or rubidium ions (Rb^+) intercalated into carbon. In another embodiment, the source of energy holes is an amalgam of the electrocatalytic ion or couple and its reduced metallic form such as rubidium ions (Rb^+) and rubidium metal or potassium ions (K^+/K^+) and potassium metal.

In an embodiment, the source of hydrogen atoms is a hydrogen dissociation means including a hydrogen gas stream blown over a hot filament or grid such as a hot refractory metal including a filament or grid of Ti, Ni, Fe, W, Au, Pt, or Pd at an elevated temperature such as 1800° C. The dissociation means provides hydrogen atoms as well as hydrogen ions, and the momentum of the atoms brings them in contact with the source of energy holes. Or, the hydrogen atoms and ions sputter onto the spillover catalyst. In one preferred embodiment of the pressurized gas reactor, a low pressure can be maintained by pressure regulator means **222** and a pump means **223** to minimize hydrogen atom recombination into molecular hydrogen and remove (molecular) lower-energy hydrogen.

In an embodiment the source of hydrogen atoms is water which dissociates to hydrogen atoms and oxygen on a water dissociation material such as an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite). In a further embodiment, the water dissociation material can be maintained at an elevated temperature by a heat source and temperature control means **230**. In an embodiment including one comprising a hydrogen spillover catalyst, the source of hydrogen can be from hydrocarbons including natural gas which can be reformed on a reforming a material such as nickel, cobalt, iron, or a platinum-group metal to hydrogen atoms and carbon dioxide. In a further embodiment, the reforming material can be maintained at an elevated temperature by a heat source and a temperature control means **230**. In another embodiment, the source of hydrogen atoms can be from the decomposition of a metal hydride where the decomposition can be controlled by controlling the temperature of the metal hydride with the heat source and temperature control means **230**. In another embodiment, the hydride can be coated by methods including electroplating with another material such as the hydrogen dissociation material.

In a preferred embodiment a product of the shrinkage reaction, (molecular) lower-energy hydrogen, can be removed to prevent product inhibition. Thus, the forward energy yielding reaction rate can be increased. One means to remove lower-energy (molecular) hydrogen is to supply the reaction mixture with a scavenger for lower-energy hydrogen. The scavenger absorbs or reacts with the product, lower-energy, hydrogen, and the resulting species can be removed from the reaction mixture. In another embodiment lower-energy hydrogen which is absorbed on the catalysts can be removed via displacement with an inert molecule or atom such as helium that flows through the vessel **200**.

Other objects, features, and characteristics of the art of catalysis as well as the methods of preparation, operation and the functions of the related elements, as described by Satterfield [Charles N. Satterfield, Heterogeneous Catalysis in Industrial Practice, Second Edition, McGraw-Hill, Inc., New York, (1991)] are applied to the present invention and are incorporated by reference herein. Application of the art of catalysis to the present invention of a pressurized gas energy reactor for the release of energy by the catalytic reaction wherein the electrons of hydrogen atoms undergo transitions to lower energy states include the use of an adiabatic reactor, fluidized-bed reactor, transport line reactor, multitube reactor, reverse multitube reactor having the heat exchange means including a fluid in the tubes and the catalytic material surrounding the tubes, and a multitube reactor or reverse multitube reactor comprising a fluidized bed of the catalytic material. Furthermore, in an embodiment comprising a solvated source of energy holes, a suspended hydrogen dissociation material including a hydrogen spillover catalyst, and hydrogen gas, the reactor comprises a trickle-bed reactor, a bubble-column reactor, or a slurry reactor.

For example, in a preferred embodiment, the fluidized bed reactor **200** comprises the hydrogen spillover catalytic material: 40% by weight potassium nitrate (KNO_3) on graphitic carbon powder with 5% by weight 1%-Pd-on-graphitic carbon powder. The reacting hydrogen gas can be passed up through a bed of the finely divided solid catalytic material, preferably having a particle size in the range of about 20 to 100 μm, which can be highly agitated and assumes many of the characteristics of a fluid. A cyclone separator **275** returns the fines to the bed. The hydrogen pressure and flow rate are controlled by pressure and flow rate control means **222**. Preferably at atmospheric or slightly higher pressures, the corresponding maximum linear velocity can be less than 60 cm/s.

Gaseous Source of Energy Holes

A preferred hydrogen gas energy reactor for the release of energy by an electrocatalytic and/or a disproportination reaction, wherein the electrons of hydrogen atoms undergo transitions to lower energy states in the gas phase, comprises a vessel **200** of FIG. **7** capable of containing a vacuum or pressures greater than atmospheric; a source of hydrogen **221**; a means **222** to control the pressure and flow of hydrogen into the vessel; a source of atomic hydrogen in the gas phase, and a source of energy holes in the gas phase.

The reaction vessel **200** comprises a vacuum or pressure vessel comprised of a temperature resistance material such as ceramic, stainless steel, tungsten, alumina, Incoloy, and Inconel.

In an embodiment, the source of hydrogen atoms in the gas phase is a hydrogen dissociation means including a hydrogen gas stream blown over a hot filament or grid **280** such as a hot refractory metal including a filament or grid of Ti, Ni, Fe, W, Au, Pt, or Pd at an elevated temperature such as 1800° C. The dissociation means provides hydrogen atoms as well as hydrogen ions, and the momentum of the atoms brings them in contact with the source of energy holes. In a preferred embodiment of the gaseous-source-of-energy-holes gas reactor, a low pressure can be maintained by pressure regulator means **222** and a pressure measurement and pump means **223** to minimize hydrogen atom recombination into molecular hydrogen. The pressure can be measured by measuring the power dissipated in the hot filament or grid which can be operated at constant resistance by a servo loop **285** comprising a voltage and current measurement means, a power supply, and a voltage and current controller where the hydrogen pressure versus power dissipation of the filament or grid at the operating resistance has been calibrated. In another embodiment, the source of atomic hydrogen comprises one or more hydrogen dissociation materials which provide hydrogen atoms by dissociation of molecular hydrogen. Such hydrogen dissociation materials include surfaces or materials to dissociate hydrogen, deuterium, or tritium, including a hydrogen spillover material such as palladium or platinum on carbon and an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite). In one embodiment, nonequilibrium conditions of the hydrogen and hydride are maintained by controlling the temperature and hydrogen pressure to provide atomic hydrogen in the gas phase. In another embodiment, the source of atomic hydrogen comprises a tungsten capillary which on the outlet can be heated by electron bombardment to 1800–2000 K such as the atomic hydrogen source described by Bischler [Bischler, U.; Bertel, E., J. Vac. Sci. Technol., A. (1993), 11(2), 458–60] which is incorporated herein by reference. In a further embodiment, the tungsten capillary can be heated by the energy released by the hydrogen shrinkage reaction. In another embodiment, the source of atomic hydrogen comprises an inductively coupled plasma flow tube such as that described by Gardner [Gardner, W. L., J. Vac. Sci. Technol., A. (1995), 13(3, Pt. 1), 763–6] which is incorporated herein by reference, and the hydrogen dissociation fraction can be measured with the sensor of Gardner.

The source of energy holes can be placed in a chemically resistant open container such as a ceramic boat **290** inside the reaction vessel. Or, the source of energy holes can be placed in a vessel which has a connection for the passage of the gaseous source of energy holes to the reaction vessel.

The cell can have a boat or container, which is connected to the reaction vessel, for containing the material used for forming the gaseous catalyst.

The gaseous source of energy holes includes those that sublime, boil, and/or are volatile at the elevated operating temperature of the gas energy reactor wherein the shrinkage reaction occurs in the gas phase. For example, $RbNO_3$ and KNO_3 are each volatile at a temperature much less than that at which each decomposes [C. J. Hardy, B. O. Field, J. Chem. Soc., (1963), pp. 5130–5134]. In one embodiment, the ionic hydrogen spillover catalytic material: 40% by weight potassium or rubidium nitrate on graphitic carbon powder with 5% by weight 1%-Pd-on-graphitic carbon powder can be operated at a temperate at which the potassium or rubidium nitrate can be volatile. Further disproportionation reactions of the product, lower-energy hydrogen atoms, release additional heat energy.

In a preferred embodiment, the source of energy holes is a thermally stable salt of rubidium or potassium such as RbF, RbCl, RbBr, RbI, Rb_2S_2, RbOH, Rb_2SO_4, Rb_2CO_3, Rb_3PO_4, and KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4,

K_2CO_3, K_3PO_4, K_2GeF_4. Further preferred sources of energy holes of approximately mX27.21 eV to cause atomic hydrogen "shrinkage" and/or approximately mX48.6 eV to cause molecular hydrogen "shrinkage" where m is an integer include the electrocatalytic ions and couples described in my previous U.S. Patent Applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989, which are incorporated herein by reference. The counterion includes those given in the Handbook of Chemistry and Physics, Robert C. Weast, Editor, 58th Edition, CRC Press, West Palm Beach, Fla., (1974) pp. B61–B178 which is incorporated by reference herein. The preferred anion can be stable to hydrogen reduction and thermal decomposition and can be volatile at the operating temperature of the energy reactor.

The catalyst may be an ionic compound which is resistant to hydrogen reduction. Moreover, the catalyst is adapted to provide gaseous atoms which may be ionized.

The following compounds are preferred gaseous sources of energy holes in the gas energy reactor. Higher temperatures result in a higher vapor pressure of the source of energy holes which increases the reaction rate; however, the increase in total pressure increases the recombination rate of hydrogen atoms to hydrogen molecules. In each exemplary case that follows, the operating temperature of the energy reactor can be that which provides an optimal reaction rate. In an embodiment, the cell temperature can be about 50° C. higher than the (highest) melting point of the source of energy holes (in the case that the source of energy holes comprises an electron transfer between two cations—an electrocatalytic couple). The hydrogen pressure can be maintained at about 200 millitorr, and molecular hydrogen can be dissociated with a hot filament or grid **280** of FIG. **7**.

Single Ion Catalysts (Electrocatalytic Ions)

Single-ion catalysts (electrocatalytic ions) capable of producing energy holes for shrinking hydrogen atoms. The number following the atomic symbol (n) is the nth ionization energy of the atom. That is for example, $Rb^+ + 27.28\ eV = Rb^{2+} + e^-$. (melting point=(MP); boiling point=(BP))

Catalytic Ion	n	nth ionization energy
Mo^{2+}	3	27.16
MoI_2		
Ti^{2+}	3	27.49
$TiCl_2$(MP = subl H_2,BP = d 475° C. vac)		
($TiCl_4/Ti_{metal}$)		
Rb^{1+}	2	27.28
$RbNO_3$(MP = 310° C.,BP = subl)		
Rb_2S_2(MP = 420° C.,BP = volat > 850)		
RbI(MP = 647° C.,BP = 1300° C.)		

Two Ion Catalyts (Electrocatalytic Couples)

Two-ion catalysts (electrocatalytic couples) capable of producing energy holes for shrinking hydrogen atoms. The number in the column following the ion, (n), is the nth ionization energy of the atom. That is for example, $K^+ + 31.63\ eV = K^{2+} + e^-$ and $K^+ + e^- = K + 4.34$ eV. (melting point=(MP); boiling point=(BP))

In an embodiment wherein the anion can be reduced by hydrogen, the anion is chemically stabilized. For example, the product of the reduction is added to the gas cell to stabilize the anion. In a further embodiment, the anion can be replaced continuously or intermittently. In the case of the nitrate ion, the product ammonia can be removed from the vessel. oxidized to nitrate, and returned to the cell. In one embodiment, the product ammonia can be removed from the vessel by collection in a condenser and can be oxidized to nitrate on a platinum or iridium screen at elevated temperatures such as 912° C. In a further embodiment, the nitrate ion to ammonia reaction can be minimized by decreasing the hydrogen pressure while optimizing the vapor phase catalytic hydrogen shrinkage reaction. In an embodiment, a low pressure of hydrogen atoms can be generated by dissociation of molecular hydrogen on a hot filament or grid **280** of FIG. **7**. A low pressure of molecular hydrogen can be maintained via the hydrogen supply **221**, the hydrogen flow control means **222**, and the hydrogen pressure measurement and vacuum means **223**. The hydrogen pressure can be maintained at a low pressure by adjusting the supply through the inlet with flow controller **222** versus the amount pumped away at the outlet by the pressure measurement and pump means **223**. The pressure can be adjusted to maximize the output power while minimizing the degradation of nitrate. The optimal hydrogen pressure can be less than about one torr. In an embodiment, the source of hydrogen atoms in the gas phase can be a hydrogen dissociation means including a hydrogen gas stream blown over a hot filament or grid **280** such as a hot refractory metal including a filament or grid of Ti, Ni, Fe, W, Au, Pt, or Pd at an elevated temperature such as 1800° C. The hydrogen molecular source can be directed over the filament or grid and onto the gaseous source of energy holes. The pressure and flow of the hydrogen atoms prohibits the collision of the counterion of the source of energy holes (such as the nitrate ion) from contacting the hot filament or grid. Thus, the thermal decomposition or reduction of the anion on the filament or grid can be prevented. In another embodiment, a negative potential can be maintained as a grid electrode **287** surrounding the filament or grid. The grid electrode permits the passage of hydrogen atoms from the filament or grid and repels the anion from contacting the hot filament or grid. Thus, the thermal or chemical breakdown of the anion (couterion) can be prevented.

In an embodiment, the source of energy holes is an electrocatalytic ion or electrocatalytic couple comprising cation-anion pairs in the gas phase wherein the cation-anion pairs are dissociated by external source means **75** of FIG. **5** which includes, for example, a particle source **75***b* and/or photon source **75***a* and/or a source of heat, acoustic energy, electric fields, or magnetic fields. In a preferred embodiment, the cation-anion pairs are thermally dissociated by heat source **230** or photodissociated by photon source **205** of FIG. **7**.

In another embodiment of the gas energy reactor having a gaseous source of energy holes, the source of energy holes is atomized with an atomizer means **295** to provide a gaseous source of energy holes. In a preferred embodiment of the atomizer, atoms are boiled, sublimed, or vaporized by a heating means such as the boat heating means **299**, and the gaseous atoms are ionized to form a source of energy holes including the electrocatalytic ions or electrocatalytic couples of my previous patent applications incorporated herein by reference. In one embodiment, the atoms are thermally ionized by the heating means **230**, by the hydrogen atom source **280** including a hot filament or grid, or by an inductively coupled plasma flow tube. For example, the gas energy cell shown in FIG. **7** comprises rubidium or potassium metal in the boat **290** which has a vapor pressure that can be controlled by controlling the temperature of the boat by heating means **230** and or **299**. Hydrogen molecules are dissociated to atoms on the hot filament or grid **280**. The rubidium (potassium) metal in the gas phase can be ionized to Rb^+ (K^+) by the same or different hot filament or grid **280**. The Rb^+ (K^+/K^+) electrocatalytic ion (couple) serves as a source of energy holes to shrink the hydrogen atoms. In another embodiment, the hot filament or grid **280** comprises a metal(s) or can be electroplated with a metal(s) which boils off as a cation(s) that are a source of energy holes. For example, Mo^{2+} ions (Mo^{2+} electrocatalytic ion) enter the gas phase of the energy cell **200** from the hot molybdenum filament or grid **280**. The hot molybdenum filament or grid **280** also dissociates hydrogen molecules to hydrogen atoms. For a further example, Ni^{2+} and Cu^+ ions (Ni^{2+}/Cu^+ electrocatalytic couple) enter the gas phase of the energy cell **200** from the hot nickel and hot copper or hot nickel-copper alloy filament or grid **280**. In another embodiment, the photon source **75***a* and the particle source **75***b* of FIG. **5**, including an electron beam, ionize species such as atoms in the gas phase to form the source of energy holes including the electrocatalytic ions or electrocatalytic couples of my previous patent applications incorporated herein by reference. In another embodiment, the atoms or ions are ionized chemically by a volatilized reactant such as an ionic species which oxidizes or reduces the atoms or ions to form a source of energy holes.

The power of the gas energy reactor can be controlled by controlling the amount of the source of energy holes (electrocatalytic ion or couple) in the gas phase and/or by controlling the concentration of atomic or lower-energy hydrogen. The concentration of the gaseous source of energy holes (electrocatalytic ion or couple) can be controlled by controlling the initial amount of the volatile source of energy holes (electrocatalytic ion or couple) present in the reactor, and/or by controlling the temperature of the reactor with temperature control means **230** which determines the vapor pressure of the volatile source of energy holes (electrocatalytic ion or couple). The reactor temperature further controls the power by changing the rate of the catalytic hydrogen shrinkage reaction. The concentration of atomic hydrogen can be controlled by controlling the amount of atomic hydrogen provided by the atomic hydrogen source **280**. For example, the amount of hydrogen atoms in the gas phase can be controlled by controlling the flow of hydrogen over or through the hot filament or grid, the tungsten capillary heated by electron bombardment, or the inductively coupled plasma flow tube; by controlling the power dissipated in the inductively coupled plasma flow tube; by controlling the temperature of the hot filament or grid, or the tungsten capillary heated by electron bombardment; by controlling the pressure of the hydrogen and temperature of the hydride maintained under nonequilibrium conditions, and by controlling the rate of removal of recombined hydrogen from the cell by pump means **223**. Another means to control the shrinkage reaction rate can be by controlling the pressure of a non reactive gas with non reactive gas source **299**, non reactive gas flow control means **232**, and pressure measurement and pump means **223**. The non reactive gas such as a noble gas competes with collisions between the source of energy holes (electrocatalytic ion or couple) and hydrogen atoms or competes with collisions that yield lower-energy hydrogen disproportionation reactions. Noble gases include He, Ne, and Ar. Further such reaction non reactive "reaction quenching" gases include carbon dioxide and nitrogen.

The hydrogen partial pressure can be further controlled by throttling hydrogen into the cell by a hydrogen value control means **222** while monitoring the pressure with a pressure measurement means **222** and **223**. In a preferred embodiment, the hydrogen pressure can be controlled by controlling the temperature with heating means **230** of the gas energy reactor which further comprises a hydrogen storage means such as a metal hydride or other hydride including saline hydrides, titanium hydride, vanadium, niobium, and tantalum hydrides, zirconium and hafnium hydrides, rare earth hydrides, yttrium and scandium hydrides, transition element hydrides, intermetalic hydrides, and their alloys known in the art as given by W. M. Mueller, J. P. Blackledge, and G. G. Libowitz, *Metal Hydrides*, Academic Press, New York, (1968), *Hydrogen in Intermetalic Compounds I*, Edited by L. Schlapbach, Springer-Verlag, Berlin, and *Hydrogen in Intermetalic Compounds II*, Edited by L. Schlapbach, Springer-Verlag, Berlin, which are incorporated by reference herein. The temperature of the cell can be controlled by a temperature control and measurement means **230** such that the vapor pressure of the hydrogen in equilibrium with the hydrogen storage material can be the desired pressure. In one embodiment, nonequilibrium conditions of the hydrogen and hydride are maintained by controlling the temperature and hydrogen pressure to provide atomic hydrogen. In several embodiments, the hydrogen storage means can be a rare earth hydride with an operating temperature of about 800° C.; lanthanum hydride with an operating temperature of about 700° C.; gadolinium hydride with an operating temperature of about 750° C.; neodymium hydride with an operating temperature of about 750° C.; yttrium hydride with an operating temperature of about 800° C.; scandium hydride with an operating temperature of about 800° C.; ytterbium hydride with an operating temperature of about 850–900° C.; titanium hydride with an operating temperature of about 450° C.; cerium hydride with an operating temperature of about 950° C.; praseodymium hydride with an operating temperature of about 700° C.; zirconium-titanium (50%/50%) hydride with an operating temperature of about 600° C.; an alkali metal/alkali metal hydride mixture such as Rb/RbH or K/KH with an operating temperature of about 450° C., and an alkaline earth metal/alkaline earth hydride mixture such as Ba/BaH_2 with an operating temperature of about 900–1000° C.

The heat output can be monitored with thermocouples present in at least the vessel **200** and the heat exchanger **60** of FIG. **5**. The rate of the shrinkage reaction rate can be monitored by ultraviolet or electron spectroscopy of the photons or electrons emitted via lower-energy hydrogen transitions, by X-ray photoelectron spectroscopy (XPS) of lower-energy hydrogen, and by mass spectroscopy, Raman or infrared spectroscopy, and gas chromatography of the molecular lower-energy hydrogen (dihydrino). Lower-energy hydrogen atoms and molecules are identified by XPS as higher binding energy species than normal hydrogen. The dihydrino can be identified by mass spectroscopy as a species with a mass to charge ratio of two (m/e=2) that has a higher ionization potential than that of normal hydrogen by recording the ion current as a function of the electron gun energy. The dihydrino can be identified by gas chromatography at low temperature such as gas chromatography with an activated carbon (charcoal) column at liquid nitrogen temperature or with a column that will separate para from ortho hydrogen such as an Rt-Alumina column, or a HayeSep column at liquid nitrogen temperature wherein normal hydrogen can be retained to a greater extent than dihydrino. The dihydrino can be identified by Raman and infrared spectroscopy as a molecule with higher vibrational and rotational energy levels as compared to those of normal hydrogen. The output power can be controlled by a computerized monitoring and control system which monitors the thermistors, spectrometers, and gas chromatograph and controls the means to alter the power output. The (molecular) lower-energy hydrogen can be removed by a means **201** to prevent the exothermic shrinkage reaction from coming to equilibrium.

In another embodiment of the gas energy reactor having a gaseous source of energy holes, hydrogen atoms are produced by a pyrolysis reaction such as the combustion of a hydrocarbon wherein the catalytic source of energy holes can be in the gas phase with the hydrogen atoms. In a preferred mode, the pyrolysis reaction occurs in an internal combustion engine whereby the hydrocarbon or hydrogen containing fuel comprises a source of energy holes that are vaporized (become gaseous) during the combustion. In a preferred mode, the source of energy holes (electrocatalytic ion or couple) is a thermally stable salt of rubidium or potassium such as RbF, RbCl, RbBr, RbI, Rb_2S_2, RbOH, Rb_2SO_4, Rb_2CO_3, Rb_3PO_4, and KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4, K_2CO_3, K_3PO_4, K_2GeF_4. Additional counterions of the electrocatalytic ion or couple include organic anions including wetting or emulsifying agents. In another embodiment, the hydrocarbon or hydrogen containing fuel further comprises water as a mixture and a solvated source of energy holes including emulsified electrocatalytic ions or couples. During the pyrolysis reaction, water serves as a further source of hydrogen atoms which undergo a shrinkage reaction catalyzed by the source of energy holes wherein the water can be dissociated to hydrogen atoms thermally or catalytically on a surface such as the cylinder or piston head which can be comprised of material which dissociates water to hydrogen and oxygen. The water dissociation material includes an element, compound, alloy, or mixture of transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U. activated charcoal (carbon), and intercalated Cs carbon (graphite).

POWER DENSITY OF GAS ENERGY REACTOR (GAS PHASE HYDROGEN SHRINKAGE REACTION)

The equations numbers which follow referred to those given by Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.]. The rate of the disproportionation reaction, $r_{m,m',p}$, to cause resonant shrinkage, Eqs. (5.22–5.30), is dependent on the collision rate between the reactants and the efficiency of resonant energy transfer. It is given by the product of the rate constant, $k_{m,m',p}$, (Eq. (5.47)), the total number of hydrogen or hydrino atoms, N_H, and the efficiency, E (Eq. (6.33)), of the transfer of the resonance shrinkage energy from the donor hydrino atom to the energy hole provided by the acceptor hydrino atom,

$$E = \frac{1}{1 + \left[\frac{r}{R_0}\right]^6} \tag{6.37}$$

$$R_0^6 = (8.8 \times 10^{-25}) J \eta^{-4} \phi_D^0 \kappa^2$$

where r is the distance between the donor and the acceptor, J is the overlap integral between the resonance shrinkage energy distribution of the donor hydrino atom and the distribution of the energy hole provided by the acceptor hydrino atom, η is the dielectric constant, and κ^2 is a function of the mutual orientation of the donor and acceptor transition moments. Electronic transitions of lower-energy hydrogen atoms occur only by nonradiative energy transfer; thus, the quantum yield of the fluorescence of the donor, Φ_D, of Eq. (6.37) is equal to one. The rate of the disproportionation reaction, $r_{m,m',p}$, to cause resonant shrinkage is

$$r_{m,m',p} = E N_H 4\pi \frac{1}{2} \sqrt{2}\, n_H \left(\frac{a_H}{p}\right)^2 \sqrt{\frac{3kT}{m_H}} \tag{6.38}$$

The factor of one half in Eq. (6.38) corrects for double counting of collisions [Levine, I., Physical Chemistry, McGraw-Hill Book Company, New York, (1978), pp. 420–421]. The power, $P_{m,m',p}$, is given by the product of the rate of the transition, Eq. (6.38), and the energy of the disproportination reaction (Eq. (5.27)).

$$P_{m,m',p} = E \frac{N_H^2}{V} 4\pi \frac{1}{\sqrt{2}} \left(\frac{a_H}{p}\right)^2 \sqrt{\frac{3kT}{m_H}} [2pm + m^2 - m'^2 + 1] \times 2.2 \times 10^{-18} \text{ W} \tag{6.39}$$

where V is the volume. For a disproportionation reaction in the gas phase, the energy transfer efficiency is one. The power given by substitution of

$$E=1,\ p=2,\ m=1,\ m'=2,\ V=1\ m^3,\ N=3\times10^{21},\ T=675\ K \tag{6.40}$$

into Eq. (6.39) is

$$P_{m,m',p}=1\text{ GW}(1\text{ kW/cm}^3) \tag{6.41}$$

In the case that the reaction of hydrogen to lower-energy states occurs by the reaction of a catalytic source of energy holes with hydrogen or hydrino atoms, the reaction rate is dependent on the collision rate between the reactants and the efficiency of resonant energy transfer. The hydrogen-or-hydrino-atom/electrocatalytic-ion collision rate per unit volume,

$$Z_{H[\frac{a_H}{p}]Catalyst},$$

for a gas containing n_H hydrogen or hydrino atoms per unit volume, each with radius

$$\frac{a_H}{p}$$

and velocity v_H and n_c electrocatalytic ions per unit volume, each with radius $r_{Catalyst}$ and velocity v_c is given by Levine [Levine, I., Physical Chemistry, McGraw-Hill Book Company, New York, (1978), pp. 420–421].

$$Z_{H[\frac{a_H}{p}]Catalyst} = \pi\left(\frac{a_H}{p} + r_{Catalyst}\right)^2\left[\langle v_H\rangle^2 + \langle v_C\rangle^2\right]^{1/2} n_H n_C \tag{6.42}$$

The average velocity, v_{avg}, can be calculated from the temperature, T, [Bueche, F. J., Introduction to Physics for Scientists and Engineers, McGraw-Hill Book Company, New York, (1986), pp. 261–265].

$$\frac{1}{2}m_H v_{avg}^2 = \frac{3}{2}kT \tag{6.43}$$

where k is Boltzmann's constant. Substitution of Eq. (5.44) into Eq. (5.42) gives the collision rate per unit volume,

$$Z_{H[\frac{a_H}{p}]Catalyst},$$

in terms of the temperature, T.

$$Z_{H[\frac{a_H}{p}]Catalyst} = \pi\left(\frac{a_H}{p} + r_{Catalyst}\right)^2\left[3kT\left(\frac{1}{m_H} + \frac{1}{m_C}\right)\right]^{1/2} n_H n_C \tag{6.44}$$

The rate of the catalytic reaction, $r_{m,p}$, to cause resonant shrinkage is given by the product of the collision rate per unit volume,

$$Z_{H[\frac{a_H}{p}]Catalyst},$$

the volume, V, and the efficiency, E, of resonant energy transfer given by Eq. (6.37).

$$r_{m,p} = E\pi\left(\frac{a_H}{p} + r_{Catalyst}\right)^2\left[3kT\left(\frac{1}{m_H} + \frac{1}{m_C}\right)\right]^{1/2}\frac{N_H N_C}{V} \tag{6.45}$$

The power, $P_{m,p}$, is given by the product of the rate of the transition, Eq. (6.45), and the energy of the transition, Eq. (5.8).

$$P_{m,p} = E\pi\left(\frac{a_H}{p} + r_{Catalyst}\right)^2\left[3kT\left(\frac{1}{m_H} + \frac{1}{m_C}\right)\right]^{1/2}\frac{N_H N_C}{V}[2mp + m^2]\times 2.2\times 10^{-18}\text{ W} \tag{6.46}$$

In the case of a gas phase catalytic shrinkage reaction wherein the source of energy holes is a single cation having an ionization energy of 27.21 eV with hydrogen or hydrino atoms, the energy transfer efficiency is one. Rubidium (Rb^+) is an electrocatalytic ion with a second ionization energy of 27.28 eV. The power for the reaction given by Eqs. (5.9). (5.10), and (5.8) with the substitution of

$$E=1,\ p=1,\ m=1,\ V=1\text{ m}^3,\ N_H=3\times10^{21},\ N_c=3\times10^{21},\ m_c=1.4\times10^{-25}\text{ kg},\ r_c=2.16\times10^{-10}\text{ m},\ T=675\text{ K} \tag{6.47}$$

into Eq. (6.46) is

$$P_{m,p}=55\text{ GW }(55\text{ kW/cm}^3) \tag{6.48}$$

In the case that the catalytic reaction of hydrogen to lower-energy states occurs on a surface, the energy transfer efficiency is less than one due to differential surface interactions of the absorbed hydrogen or hydrino atoms and the electrocatalytic ion. The power given by Eqs. (6.46) and (6.47) with

$$E=0.001 \tag{6.49}$$

is

$$P_{m,p}=55\text{ MW }(55\text{ W/cm}^3) \tag{6.50}$$

Less efficient catalytic systems hinge on the coupling of three resonator cavities. For example, an electron transfer occurs between two cations which comprises an energy hole for a hydrogen or hydrino atom. The reaction rate is dependent on the collision rate between catalytic cations and hydrogen or hydrino atoms and the efficiency of resonant energy transfer with a concomitant electron transfer with each shrinkage reaction. The rate of the catalytic reaction, $r_{m,p}$, to cause resonant shrinkage is given by the product of the collision rate per unit volume,

$$Z_{H[\frac{a_H}{p}]Catalyst},$$

the volume, V, and the efficiency, E_e, of resonant energy transfer given by Eq. (6.37) where r is given by the average distance between cations in the reaction vessel.

$$r_{m,p} = E_c\pi\left(\frac{a_H}{p} + r_{Catalyst}\right)^2\left[3kT\left(\frac{1}{m_H} + \frac{1}{m_C}\right)\right]^{1/2}\frac{N_H N_C}{V} \tag{6.51}$$

The power, $P_{m,p}$, is given by the product of the rate of the transition, Eq. (6.51), and the energy of the transition, Eq. (5.8).

$$P_{m,p} = E_c\pi\left(\frac{a_H}{p} + r_{Catalyst}\right)^2\left[3kT\left(\frac{1}{m_H} + \frac{1}{m_C}\right)\right]^{1/2}\frac{N_H N_C}{V}[2mp + m^2]\times 2.2\times 10^{-18}\text{ W} \tag{6.52}$$

A catalytic system that hinges on the coupling of three resonator cavities involves potassium. For example, the second ionization energy of potassium is 31.63 eV. This energy hole is obviously too high for resonant absorption. However, K^+ releases 4.34 eV when it is reduced to K. The combination of K^+ to K^{2+} and K^+ to K, then, has a net energy change of 27.28 eV. Consider the case of a gas phase catalytic shrinkage reaction of hydrogen or hydrino atoms by potassium ions as the electrocatalytic couple having an energy hole of 27.28 eV. The energy transfer efficiency is given by Eq. (6.37) where r is given by the average distance between cations in the reaction vessel. When the K^+ concentration is

$$3\times10^{22}\frac{K^+}{m^3},$$

r is approximately 5×10^{-9} m. For $J=1$, $\Phi_D=1$, $\kappa^2=1$, $\tau_D=10^{-13}$ sec (based on the vibrational frequency of KH^+), and m=1 in Eq. (5.8), the energy transfer efficiency, E_c, is approximately 0.001. The power for the reaction given by Eqs. (5.13), (5.14), and (5.8) with the substitution of

$$E=0.001,\ p=1,\ m=1,\ V=1\ m^3,\ N_H=3\times10^{22},\ N_c=3\times10^{21},\ m_c=6.5\times10^{-26}\ kg,\ r_c=1.38\times10^{-10}\ m,\ T=675\ K \tag{6.53}$$

into Eq. (6.52) is

$$P_{m,p}=300\ MW\ (300\ W/cm^3) \tag{6.54}$$

Gas Discharge Energy Reactor

A gas discharge energy reactor comprises a hydrogen isotope gas filled glow discharge vacuum chamber **300** of FIG. **8** including an ozonizer-type capacitor, a hydrogen source **322** which supplies hydrogen to the chamber **300** through control valve **325**, and a voltage and current source **330** to cause current to pass between a cathode **305** and an anode **320**. In one embodiment comprising an ozonizer-type capacitor gas discharge cell, one of the electrodes can be shielded by a dielectric barrier such as glass or a ceramic moiety. In a preferred embodiment, the cathode further comprises a source of energy holes of approximately mX27.21 eV to cause atomic hydrogen "shrinkage" and/or approximately mX48.6 eV to cause molecular hydrogen "shrinkage" where m is an integer (including the electrocatalytic ions and couples described in my previous U.S. patent applications entitled "Energy/Matter Conversion Methods and Structures", Ser. No. 08/467,051 filed on Jun. 6, 1995 which is a continuation-in-part application of Ser. No. 08/416,040 filed on Apr. 3, 1995 which is a continuation-in-part application of Ser. No. 08/107,357 filed on Aug. 16, 1993, which is a continuation-in-part application of Ser. No. 08/075,102 (Dkt. 99437) filed on Jun. 11, 1993, which is a continuation-in-part application of Ser. No. 07/626,496 filed on Dec. 12, 1990 which is a continuation-in-part application of Ser. No. 07/345,628 filed Apr. 28, 1989 which is a continuation-in-part application of Ser. No. 07/341,733 filed Apr. 21, 1989 which are incorporated by reference). A preferred cathode **305** for shrinking hydrogen atoms is a palladium cathode whereby a resonant energy hole can be provided by the ionization of electrons from palladium to the discharge current. A second preferred cathode **305** for shrinking hydrogen atoms comprises a source of energy holes via electron transfer to the discharge current including at least one of beryllium, copper, platinum, zinc, and tellurium and a hydrogen dissociating means such as a source of electromagnetic radiation including UV light provided by photon source **350** or a hydrogen dissociating material including the transition elements and inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal (carbon), and intercalated Cs carbon (graphite). The reactor further comprises a means to control the energy dissipated in the discharge current when electrons are transferred from an electron donating species to provide an energy hole for hydrogen atoms (molecules) including pressure controller means **325** and current (voltage) source **330**. The gas discharge energy reactor further comprises a means **301** to remove the (molecular) lower-energy hydrogen such as a selective venting valve to prevent the exothermic shrinkage reaction from coming to equilibrium.

In another embodiment of the gas discharge energy reactor, the source of energy hole can be one of a inelastic photon or particle scattering reaction(s). In a preferred embodiment the photon source **350** supplies the energy holes where the energy hole corresponds to stimulated emission by the photon. In the case of a reactor which shrinks hydrogen atoms, the photon source **350** dissociates hydrogen molecules into hydrogen atoms. The photon source producing photons of at least one energy of approximately mX27.21 eV,

$$\frac{m}{2}\times27.21\text{ eV},$$

or 40.8 eV causes stimulated emission of energy as the hydrogen atoms undergo the shrinkage reaction. In another preferred embodiment, a photon source **350** producing photons of at least one energy of approximately mX48.6 eV, 95.7 eV, or mX31.94 eV causes stimulated emission of energy as the hydrogen molecules undergo the shrinkage reaction.

In another embodiment, a magnetic field can be applied by magnetic field generator **75** of FIG. **5** to produce a magnetized plasma of the gaseous ions which can be a nonlinear media. Coupling of resonator cavities and enhancement of the transfer of energy between them can be increased when the media is nonlinear. Thus, the reaction rate (transfer of the resonance shrinkage energy of the hydrogen atoms to the energy holes, the electrocatalytic ions or couples) can be increased and controlled by providing and adjusting the applied magnetic field strength.

In one embodiment of the method of operation of the gas discharge energy reactor, hydrogen from source **322** can be introduced inside of the chamber **300** through control valve **325**. A current source **330** causes current to pass between a cathode **305** and an anode **320**. The hydrogen contacts the cathode which comprises a source of energy holes of approximately mX27.21 eV to cause atomic hydrogen "shrinkage" and approximately mX48.6 eV to cause molecular hydrogen "shrinkage" where m is an integer. In a preferred embodiment, electrons are transferred from an electron donating species present on the cathode **305** to the discharge current to provide energy holes for hydrogen atoms (molecules). In the case of a reactor which shrinks hydrogen atoms, the molecular hydrogen can be dissociated into atomic hydrogen by a dissociating material on the cathode **305** or by a source of electromagnetic radiation including UV light provided by photon source **350** such that the dissociated hydrogen atoms contact a source of energy holes including a molten, liquid, gaseous, or solid source of the energy holes. The atomic (molecular) hydrogen releases energy as its electrons are stimulated to undergo transitions to lower energy levels by the energy holes. The energy dissipated in the discharge current when electrons are transferred from an electron donating species can be controlled to provide an energy hole equal to the resonance shrinkage energy for hydrogen atoms (molecules) by controlling the gas pressure from source **322** with pressure controller means **325** and the voltage with the current (voltage) source **330**. The heat output can be monitored with thermocouples present in at least the cathode **305**, the anode **320**, and the heat exchanger **60** of FIG. **5**. The output power can be controlled by a computerized monitoring and control system which monitors the thermistors and controls the means to alter the power output. The (molecular) lower-energy hydrogen can be removed by a means **301** to prevent the exothermic shrinkage reaction from coming to equilibrium.

In another embodiment of the gas discharge energy reactor, a preferred cathode **305** comprises the catalytic material including a spillover catalyst described in the Pressurized Gas Energy Reactor Section.

Another embodiment of the gas discharge energy reactor comprises a gaseous source of energy holes wherein the shrinkage reaction occurs in the gas phase, and the gaseous hydrogen atoms are provided by a discharge of molecular hydrogen gas. In a further embodiment the gaseous source of energy holes can be provided by a discharge current which produces the gaseous source of energy holes (electrocatalytic ion or couple) such as a discharge in potassium metal to form K^+/K^+, rubidium metal to form Rb^+, or titanium metal to form Ti^{2+}. The embodiment comprises a hydrogen isotope gas filled glow discharge chamber **300**. The glow discharge cell can be operated at an elevated temperature such this the source of energy holes (electrocatalytic ion or couple) can be sublimed, boiled, or volatilized into the gas phase. In an embodiment, the counterion of the source of energy holes (electrocatalytic ion or couple) can be the hydride anion (H^-) such as rubidium hydride (Rb^+ electrocatalytic ion) and/or potassium hydride (K^+/K^+ electrocatalytic couple).

In an embodiment, the source of energy holes can be an electrocatalytic ion or electrocatalytic couple comprising cation-anion pairs in the gas phase wherein the cation-anion pairs are dissociated by external source means **75** of FIG. **5** which includes, for example, a particle source **75*b*** and/or photon source **75*a*** and/or a source of heat, acoustic energy, electric fields, or magnetic fields. In a preferred embodiment, the cation-anion pairs are thermally dissociated by heat source **75** of FIG. **5** or photodissociated by photon source **350** of FIG. **8**.

Refrigeration Means

A further embodiment of the present invention comprises a refrigeration means which comprises the electrolytic cell of FIG. **6**, the pressurized hydrogen gas cell of FIG. **7**, and the hydrogen gas discharge cell of FIG. **8** of the present invention wherein a source of lower-energy atomic (molecular) hydrogen is supplied rather than a source of normal hydrogen. The lower-energy hydrogen atoms are reacted to a higher energy state with the absorption of heat energy according to the reverse of the catalytic shrinkage reaction such as those given by Eqs. (4–6); (7–9); (10–12); (13–15); (16–18); (48–50); (51–53); (54–56); (57–59); (60–62), (63–65), (66–68), (69–71), (72–74), and (75–77). The lower-energy hydrogen molecules are reacted to a higher energy state with the absorption of heat energy according to the reverse of the catalytic shrinkage reaction such as that given by Eqs. (78–80); (81–83); (84–86); (88–90), and (91–93). In this embodiment, means **101**, **201** and **301** of FIGS. **6**, **7**, and **8**, respectively, serve to remove the normal hydrogen such as a selective venting valves to prevent the endothermic reaction from coming to equilibrium.

Compositions of Matter Comprising at Least Lower-Energy Hydrogen Atom(s) and/or Lower-energy Hydrogen Molecule(s)

The present invention further comprises molecules containing lower-energy hydrogen atoms. Lower-energy hydrogen can be reacted with any atom of the periodic chart or known organic or inorganic molecule or compound or metal, nonmetal, or semiconductor to form an organic or inorganic molecule or compound or metal, nonmetal, or semiconductor containing lower-energy hydrogen atoms and molecules. The reactants with lower-energy hydrogen include neutral atoms, negatively or positively charged atomic and molecular ions, and free radicals. For example, lower-energy hydrogen can be reacted with water or oxygen to form a molecule containing lower-energy hydrogen and oxygen, and lower-energy hydrogen can be reacted with singly ionized helium to form a molecule containing helium and lower-energy hydrogen. Lower-energy hydrogen can be also reacted with metals. In one embodiment of the electrolytic cell energy reactor, lower-energy hydrogen produced during operation at the cathode can be incorporated into the cathode by reacting with it; thus, a metal-lower-energy hydrogen material can be produced. In all such reactions, the reaction rate and product yield are increased by applying heat, and/or pressure.

Lower-energy hydrogen molecules (dihydrinos) are purified from hydrogen gas by combustion of the normal hydrogen. Oxygen can be mixed with the sample to be purified, and the sample can be ignited. In a second embodiment of the method of dihydrino purification, the sample can be flowed over a hydrogen recombiner which reacts with the normal hydrogen in the gas stream to form water. In a third embodiment, lower-energy hydrogen molecules (dihydrinos) are collected in a cathode of an electrolytic energy reactor of the present invention such as a metal cathode including a nickel cathode or a carbon cathode. The cathode can be heated in a vessel to a first temperature which causes normal hydrogen to preferentially off gas by external heating or by flowing a current through the cathode. The normal hydrogen can be pumped off, then the cathode can be heated to a second higher temperature at which dihydrino gas can be released and collected. In a fourth embodiment, the gas sample is purified by cryofiltration including gas chromatography at low temperature such as gas chromatography with an activated carbon (charcoal) column at liquid nitrogen temperature and with a column which will separate para from ortho hydrogen such as an Rt-Alumina column, or a HayeSep column at liquid nitrogen temperature wherein normal hydrogen can be retained to a greater extent than dihydrino. In a fifth embodiment, the gas sample is purified by cryodistillation wherein normal hydrogen can be liquefied and separated from gaseous lower-energy hydrogen (dihydrino). The dihydrino can be concentrated by liquefaction in liquid helium.

EXPERIMENTAL VERIFICATION OF THE PRESENT THEORY

EXAMPLE 1

The article by Mills and Good [Mills, R., Good, W., "Fractional Quantum Energy Levels of Hydrogen", Fusion Technology, Vol. 28, No. 4, November, (1995), pp. 1697–1719] describes the determination of excess heat release during the electrolysis of aqueous potassium carbonate by the very accurate and reliable method of heat measurement, flow calorimetry; describes the experimental identification of hydrogen atoms in fractional quantum energy levels—hydrinos—by X-ray Photoelectron Spectroscopy (XPS); describes the experimental identification of hydrogen atoms in fractional quantum energy levels—hydrinos—by emissions of soft x-rays from dark matter; describes the experimental identification of hydrogen molecules in fractional quantum energy levels—dihydrino molecules by high resolution magnetic sector mass spectroscopy with ionization energy determination, and gives a summary.

In Summary

The complete theory which predicts fractional quantum energy levels of hydrogen and the exothermic reaction whereby lower-energy hydrogen is produced is given elsewhere [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa., provided by HydroCatalysis Power Corporation, Great Valley Corporate Center, 41 Great Valley Parkway, Malvern, Pa., 19355, R. Mills; *Unification of Spacetime, the Forces, Matter, and Energy* (Technomic Publishing Company, Lancaster, Pa., 1992)].

Excess power and heat were observed during the electrolysis of aqueous potassium carbonate. Flow calorimetry of pulsed current electrolysis of aqueous potassium carbonate at a nickel cathode was performed in a single-cell dewar. The average power out of 24.6 watts exceeded the average input power (voltage times current) of 4.73 watts by a factor greater than 5. The total input energy (integration of voltage times current) over the entire duration of the experiment was 5.72 MJ; whereas, the total output energy was 29.8 MJ. No excess heat was observed when the electrolyte was changed from potassium carbonate to sodium carbonate. The source of heat is assigned to the electrocatalytic, exothermic reaction whereby the electrons of hydrogen atoms are induced to undergo transitions to quantized energy levels below the conventional "ground state". These lower energy states correspond to fractional quantum numbers: $n=\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots$. Transitions to these lower energy states are stimulated in the presence of pairs of potassium ions (K^+/K^+ electrocatalytic couple) which provide 27.2 eV energy sinks.

The identification of the $n=\frac{1}{2}$ hydrogen atom , $H(n=\frac{1}{2})$ is reported. Samples of the nickel cathodes of aqueous potassium carbonate electrolytic cells and aqueous sodium carbonate electrolytic cells were analyzed by XPS. A broad peak centered at 54.6 eV was present only in the cases of the potassium carbonate cells. The binding energy (in vacuum) of $H(n=\frac{1}{2})$ is 54.4 eV. Thus, the theoretical and measured binding energies for $H(n=\frac{1}{2})$ are in excellent agreement.

Further experimental identification of hydrinos—down to $H(n=\frac{1}{8})$—can be found in the alternative explanation by Mills et al. for the soft X-ray emissions of the dark interstellar medium observed by Labov and Bowyer [S. Labov and S. Bowyer, Astrophysical Journal, 371 (1991) 810] of the Extreme UV Center of the University of California, Berkeley. The agreement between the experimental spectrum and the energy values predicted for the proposed transitions is remarkable.

The reaction product of two $H(n=\frac{1}{2})$ atoms, the dihydrino molecule, was identified by mass spectroscopy (Shrader Analytical & Consulting Laboratories). The mass spectrum of the cryofiltered gases evolved during the electrolysis of a light water K_2CO_3 electrolyte with a nickel cathode demonstrated that the dihydrino molecule, $H_2(n=\frac{1}{2})$, has a higher ionization energy, about 63 eV, than normal molecular hydrogen, $H_2(n=1)$, 15.46 eV. The high resolution (0.001 AMU) magnetic sector mass spectroscopic analysis of the postcombustion gases indicated the presence of two peaks of nominal mass two at 70 eV and one peak at 25 eV. The same analysis of molecular hydrogen indicates only one peak at 25 eV and one peak at 70 eV. In the case of the postcombustion sample at 70 eV, one peak was assigned as the hydrogen molecular ion peak, $H_2^+(n=1)$, and one peak was assigned as the dihydrino molecular peak, $H_2^+(n=\frac{1}{2})$ which has a slightly larger magnetic moment.

EXAMPLE 2

In the January 1994 edition of Fusion Technology, [Mills, R., Good, W., Shaubach, R., "Dihydrino Molecule Identification", Fusion Technology, 25, 103 (1994)] Mills et al. review and present three sets of data of heat production and "ash" identification including the work of HydroCatalysis Power Corporation (Experiments #1–#3) and Thermacore, Inc. (Experiments #4–#14).

In Summary

Mills et al. report the experimental evidence supporting the Mills theory that an exothermic reaction occurs wherein the electrons of hydrogen atoms and deuterium atoms are stimulated to relax to quantized potential energy levels below that of the "ground state" via electrochemical reactants K^+ and K^+; Pd^{2+} and Li^+, or Pd and O_2 of redox energy resonant with the energy hole which stimulates this transition. Calorimetry of pulsed current and continuous electrolysis of aqueous potassium carbonate (K^+/K^+ electrocatalytic couple) at a nickel cathode was performed. The excess power out of 41 watts exceeded the total input power given by the product of the electrolysis voltage and current by a factor greater than 8. The "ash" of the exothermic reaction is atoms having electrons of energy below the "ground state" which are predicted to form molecules. The predicted molecules were identified by lack of reactivity with oxygen, by separation from molecular deuterium by cryofiltration, and by mass spectroscopic analysis.

The combustion of the gases evolved during the electrolysis of a light water K_2CO_3 electrolyte (K^+/K^+ electrocatalytic couple) with a nickel cathode was incomplete. The mass spectroscopic analysis (Air Products & Chemicals, Inc.) of uncombusted gases demonstrated that the species predominantly giving rise to the m/e=2 peak must have a different m/e=1 to m/e=2 production efficiency than hydrogen. And, the further mass spectroscopic analysis of the m/e=2 peak of the uncombusted gas demonstrated that the dihydrino molecule, $H_2(n=\frac{1}{2})$, has a higher ionization energy than H_2.

According to the analysis by Mills et al. of the raw data, Miles of the China Lake Naval Air Warfare Center Weapons Division observed the dideutrino molecule as a species with a mass to charge ratio of four and having a higher ionization potential than normal molecular deuterium. Miles was using mass spectroscopy to analyze the cryofiltered gases evolved from excess power producing electrolysis cells (palladium cathode and a $LiOD/D_2O$ electrolyte; an electrocatalytic couple of 27.54 eV). [B. F. BUSH, J. J. LAGOWSKI, M. H. MILES, and G. S. OSTROM, "Helium Production During the Electrolysis of D_2O in Cold Fusion Experiments", J. Electroanal. Chem., 304, 271 (1991); M. H. MILES, B. F. BUSH, G. S. OSTROM, and J. J. LAGOWSKI, "Heat and Helium Production in Cold Fusion Experiments", Proc. Conf. The Science of Cold Fusion, Como, Italy, Jun. 29–Jul. 4, 1991, p. 363, T. BRESSANI, E. DEL GIUDICE, and G. PREPARATA, Eds., SIF (1991); M. H. MILES, R. A. HOLLINS, B. F. BUSH, J. J. LAGOWSKI, and R. E. J. MILES, "Correlation of Excess Power and Helium Production During D_2O and H_2O Electrolysis Using Palladium Cathodes", J. Electroanal. Chem., 346, 99 (1993); M. H. MILES and B. F. BUSH, "Search for Anomalous Effects Involving Excess Power and Helium During D_2O Electrolysis Using Palladium Cathodes," Proc. 3rd Int. Conf. Cold Fusion, Nagoya, Japan, Oct. 21–25, 1992, p. 189].

Palladium sheets coated on one side with a hydrogen impermeant gold layer and coated on the other surface with an oxide coat (MnO_x, AlO_x, SiO_x) were deuterium or hydrogen loaded at NTT Laboratories. Heat was observed from light and heavy hydrogen only when the mixed oxide coat was present (Pd/O_2 electrocatalytic couple). The high resolution (0.001 AMU) quadrapole mass spectroscopic analysis of the gases released when a current was applied to a deuterium (99.9%) loaded MnO_x coated palladium sheet indicate the presence of a large shoulder on the D_2 peak which Mills et al. assign to the dideutrino molecule, $D_2(n=\frac{1}{2})$. [E. YAMAGUCHI and T. NISHIOKA, "Direct Evidence for Nuclear Fusion Reactions in Deuterated Palladium," Proc. 3rd Int. Conf. Cold Fusion,, Nagoya, Japan, October 21–25, 1992, p. 179; E. YAMAGUCHI and T. NISHIOKA, "Helium-4 Production from Deuterated Palladium at Low Energies," NTT Basic Research Laboratories and IMRA Europe S. A., Personal Communication (1992)].

EXAMPLE 3

Pennsylvania State University has determined excess heat release from flowing hydrogen in the presence of nickel oxide powder containing strontium niobium oxide (Nb^{3+}/Sr^{2+} electrocatalytic couple) by the very accurate and reliable method of heat measurement, thermopile conversion of heat into an electrical output signal [Phillips, J., "A Calorimetric Investigation of the Reaction of Hydrogen with Sample PSU #1", Sep. 11, 1994, A Confidential Report submitted to HydroCatalysis Power Corporation provided by HydroCatalysis Power Corporation, Great Valley Corporate Center, 41 Great Valley Parkway, Malvern, Pa. 19355]. Excess power and heat were observed with flowing hydrogen over the catalyst which increased with increasing flow rate. However, no excess power was observed with flowing helium over the catalyst/nickel oxide mixture or flowing hydrogen over nickel oxide alone. As shown in FIG. **9**, approximately 10 cc of nickel oxide powder containing strontium niobium oxide immediately produced 0.55 W of steady state output power at 523° K. When the gas was switched from hydrogen to helium, the power immediately dropped. The switch back to hydrogen restored the excess power output which continued to increase until the hydrogen source cylinder emptied at about the 40,000 second time point. With no hydrogen flow the output power fell to zero.

The source of heat is assigned to the electrocatalytic, exothermic reaction whereby the electrons of hydrogen atoms are induced to undergo transitions to quantized energy levels below the conventional "ground state". These lower energy states correspond to fractional quantum numbers: $n=\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots$. Transitions to these lower energy states are stimulated in the presence of pairs of niobium and strontium ions (Nb^{3+}/Sr^{2+} electrocatalytic couple) which provide 27.2 eV energy sinks.

EXAMPLE 4

The article in the Spectral Data of Hydrinos from the Dark Interstellar Medium and from the Sun Section of Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.] describes the experimental identification of hydrogen atoms in fractional quantum energy levels—hydrinos—by emissions of soft X-rays from dark matter and the Sun; provides a resolution to the Solar Neutrino Problem, the Temperature of the Solar Corona Problem, the Broadening of the Hydrogen 911.8 Å Line Problem, the Temperature of the Transition from "Radiation Zone" to "Convection Zone" Problem, the Cool Carbon Monoxide Clouds Problem, the Stellar Age Problem, the Solar Rotation Problem, the Solar Flare Problem, and the problem of the ionizing energy source of hydrogen planets, and describes the experimental identification of hydrogen atoms in fractional quantum energy levels—hydrinos—by spin/nuclear hyperfine structure transition energies obtained by COBE for which no other satisfactory assignment exists.

In Summary

As shown in Table 1 Mills [Mills, R., *The Grand Unified Theory of Classical Quantum Mechanics*, (1995), Technomic Publishing Company, Lancaster, Pa.], hydrogen transitions to electronic energy levels below the "ground" state corresponding to fractional quantum numbers predicted by Mills' theory match the spectral lines of the extreme ultraviolet background of interstellar space. And, hydrogen disproportionation reactions yield ionized hydrogen, energetic electrons, and hydrogen ionizing radiation. This assignment resolves the paradox of the identity of dark matter and accounts for many celestial observations such as: diffuse Hα emission is ubiquitous throughout the Galaxy, and widespread sources of flux shortward of 912 Å are required [Labov, S., Bowyer, S., "Spectral observations of the extreme ultraviolet background", The Astrophysical Journal, 371, (1991), pp. 810–819].

Further experimental identification of hydrinos-down to $H(n=\frac{1}{8})$—can be found in the alternative explanation by Mills for the soft X-ray emissions of the dark interstellar medium observed by Labov and Bowyer [S. Labov and S. Bowyer, Astrophysical Journal, 371 (1991) 810] of the Extreme UV Center of the University of California, Berkeley. The agreement between the experimental spectrum and the energy values predicted for the proposed transitions is remarkable.

The paradox of the paucity of solar neutrinos to account for the solar energy output by the pp chain is resolved by assigning a major portion of the solar output to lower-energy hydrogen transitions. The photosphere of the Sun is 6000 K; whereas, the temperature of the corona based on the assignment of the emitted X-rays to highly ionized heavy elements is in excess of 10^6 K. No satisfactory power transfer mechanism is known which explains the excessive temperature of the corona relative to that of the photosphere. The paradox is resolved by the existence of a power source associated with the corona. The energy which maintains the corona at a temperature in excess of 10^6 K is that released by disproportionation reactions of lower-energy hydrogen as given by Eqs. (13–15). In Table 2 of Mills, the energy released by the transition of the hydrino atom with the initial lower-energy state quantum number p and radius

$$\frac{a_H}{p}$$

to the state with lower-energy state quantum number (p+m) and radius

$$\frac{a_H}{(p+m)}$$

catalyzed by a hydrino atom with the initial lower-energy state quantum number m', initial radius

$$\frac{a_H}{m'},$$

and final radius a_H are given in consecutive order of energy from the 1→½ H transition to the ⅑→⅒ H transition. The agreement between the calculated and the experimental values is remarkable. Furthermore, many of the lines of Table 2 had no previous assignment, or the assignment was unsatisfactory [Thomas, R. J., Neupert. W., M., Astrophysical Journal Supplement Series, Vol. 91, (1994), pp. 461–482; Malinovsky, M., Heroux, L., Astrophysical Journal, Vol. 181, (1973), pp. 1009–1030; Noyes, R., *The Sun, Our Star*, Harvard University Press, Cambridge, Ma., (1982), p. 172; Phillips, J. H., *Guide to the Sun*, Cambridge University Press, Cambridge, Great Britain, (1992), pp. 118–119; 120–121; 144–145]. The calculated power of 4×10^{26} W matches the observed power output of 4×10^{26} W.

The broadening of the solar HI911.8 Å line (911.8 Å to ≈600 Å) is six times that predicted based on the thermal electron energy at the surface of the photosphere (T=6,000 K) where the HI 911.8 Å continuum originates, and based on the relative width of the helium continuum lines, He I 504.3 Å (He I 504.3 Å to ≈530 Å) and He II 227.9 Å (He II 227.9 Å to ≈225 Å) [Thomas, R. J., Neupert, W., M., Astrophysical Journal Supplement Series, Vol. 91, (1994), pp. 461–482; Stix, M., *The Sun*, Springer-Verlag, Berlin, (1991), pp. 351–356; Malinovsky, M., Heroux, L.. Astrophysical Journal, Vol. 181, (1973), pp. 1009–1030; Noyes, R., *The Sun, Our Star*, Harvard University Press, Cambridge, Ma., (1982), p. 172; Phillips, J. H., *Guide to the Sun*, Cambridge University Press, Cambridge, Great Britain, (1992), pp. 118–119; 120–121; 144–145]. The latter lines are proportionally much narrower; yet, the corresponding temperatures of origin must be higher because the transitions are more energetic. Furthermore, the H 911.8 Å continuum line of the spectrum of a prominence is about one half the width of the same line of the quiet Sun spectrum. Yet, the temperature rises to greater than 10,000 K in a prominence. The problem of the anomalous spectral feature of the excessive broadening of the continuum line of hydrogen to higher energies can be resolved by assignment of the broadening mechanism to energetic disproportionation reactions involving hydrogen atoms as reactants.

The reaction product, lower-energy hydrogen, can be reionized as it is diffuses towards the center of the Sun. The abrupt change in the speed of sound and transition from "radiation zone" to "convection zone" at a radius of 0.7 the solar radius, 0.7 R_s, with a temperature of 2×10^6 K matches the ionization temperature of lower-energy hydrogen.

Another spectroscopic mystery concerns an infrared absorption band of the chromosphere at a wavelength of 4.7 μm which was previously assigned to carbon monoxide despite the implausibility of its existence in the observed region which has a temperature above that at which carbon monoxide would break up into its constituent carbon and oxygen atoms. This problem can be resolved by assignment of the broad 4.7 μm feature to a temperature broadened rotational transition of a molecular ion of lower-energy hydrogen. The assignment of the 4.7 μm absorption line to the J=0 to J=1 transition rotational transition of $H_2^*[2c'=3a_o]^+$ provides a resolution of the problem of cool carbon monoxide clouds.

Modeling how stars evolve leads to age estimates for some stars that are greater than the age of the universe. Mills' theory predicts that presently, stars exist which are older than the elapsed time of the present expansion as stellar evolution occurred during the contraction phase.

General Relativity provides a resolution to the problem of the loss of angular momentum of the core which is in agreement with the current Solar models and helioseismology data. The photon transfer of momentum to expanding spacetime mechanism provides a resolution to the solar rotation problem of the slowly rotating Solar core.

Further stellar evidence of disproportionation reactions is the emission of extreme ultraviolet radiation by young stars called A stars. They appear to have energetic, ultraviolet-emitting upper atmospheres, or coronas, even though astronomers believe such stars lack the ability to heat these regions.

Numerous late-type stars, particularly dM stars, are known to flare from time to time at visible and X-ray wavelengths. An extremely pronounced flare was observed by the Extreme Ultraviolet Explorer (EUVE) Deep Survey telescope on the star AU Microscopii at a count of 20 times greater than that at quiescence [Bowyer, S., Science, Vol. 263, (1994), pp. 55–59]. Emission lines in the extreme ultraviolet were observed for which there is no satisfactory assignment. These spectral lines match hydrogen transitions to electronic energy levels below the "ground" state corresponding to fractional quantum numbers as shown in Table 3 of Mills. The lines assigned to lower-energy hydrogen transitions increased significantly in intensity during the flare event. The data is consistent with disproportionation reactions of lower-energy hydrogen as the mechanism of solar flare activity.

Planetary evidence of disproportionation reactions is the emission of energy by Jupiter, Saturn, and Uranus in excess of that absorbed from the Sun. Jupiter is gigantic ball of gaseous hydrogen. Saturn and Uranus are also largely comprised of hydrogen. H_3^+ is detected from all three planets by infrared emission spectroscopy [J. Tennyson, Physics World, July, (1995), pp. 33–36]. Disproportionation reactions of hydrogen yield ionizing electrons, energy, and ionized hydrogen atoms. Ionizing electrons and protons can both react with molecular hydrogen to produce H_3^+.

The spin/nuclear hyperfine structure transition energies of lower-energy hydrogen match closely certain spectral lines obtained by COBE [E. L. Wright, et. al., The Astrophysical Journal, 381, (1991), pp. 200–209; J. C. Mather, et. al., The Astrophysical Journal, 420, (1994), pp. 439–444] for which no other satisfactory assignment exists.

EXAMPLE 5

Pennsylvania State University has determined excess heat release from flowing hydrogen in the presence of ionic hydrogen spillover catalytic material: 40% by weight potassium nitrate (KNO_3) on graphitic carbon powder with 5% by weight 1%-Pd-on-graphitic carbon (K^+/K^+ electrocatalytic couple) by the very accurate and reliable method of heat measurement, thermopile conversion of heat into an electrical output signal [Phillips, J., Shim, H., "Additional Calorimetric Examples of Anomalous Heat from Physical Mixtures of K/Carbon and Pd/Carbon", Jan. 1, 1996, A Confidential Report submitted to HydroCatalysis Power Corporation provided by HydroCatalysis Power Corporation, Great Valley Corporate Center, 41 Great Valley Parkway, Malvern, Pa. 19355]. Excess power and heat were observed with flowing hydrogen over the catalyst. However, no excess power was observed with flowing helium over the catalyst mixture. Rates of heat production were reproducibly observed which were higher than that expected from the conversion of all the hydrogen entering the cell to water, and the total energy observed was over four times larger than that expected if all the catalytic material in the cell were converted to the lowest energy state by "known" chemical reactions. Thus, "anomalous" heat, heat of a magnitude and duration which could not be explained by conventional chemistry, was reproducibly observed.

EXAMPLE 6

Excess heat from a pressurized gas energy cell having a gaseous source of energy holes has been observed by HydroCatalysis Power Corporation [manuscript in progress] with low pressure hydrogen in the presence of molybdenum iodide (MoI_2) (Mo^{2+} electrocatalytic ion) which was volatilized at the operating temperature of the cell, 210° C. The calorimeter was placed inside a large convection oven that maintained the ambient temperature of the cell at the operating temperature. The cell comprised a 40 cc stainless steel pressure vessel that was surrounded by a 2 inch thick molded ceramic thermal insulator. The cell was sealed with a vacuum tight flange that had a two hole Buffalo gland for a tungsten wire to dissociate molecular hydrogen, a perforation for a Type K thermocouple, a 1/16 inch inlet for hydrogen which was connected to a 1/4 inch stainless steel tube which connected to the hydrogen supply. The flange was sealed with a copper gasket. The bottom of the vessel had a 1/4" vacuum port connected to a stainless steel tube with a valve between the cell and a vacuum pump and vacuum gauge. Less than one gram of MoI_2 catalyst was placed in a ceramic boat inside the vessel. The vapor pressure of the catalyst was estimated to be about 50 millitorr at the operating temperature 210° C. The hydrogen pressure of about 200 to 250 millitorr was controlled manually by adjusting the supply through the inlet versus the amount pumped away at the outlet where the pressure was monitored in the outlet tube by the vacuum gauge. For each run, the total pressure was made (including the MoI_2 pressue in the case of the experimental run) precisely 250 millitorr.

The output power was determined by measuring difference between the cell temperature and the ambient oven temperature and comparing the result to a calibration curve generated by applying power to the inside of the cell with the tungsten filament. Excess power of 0.3 watts was observed from the 40 cc stainless steel reaction vessel containing less than 1 g of MoI_2 when hydrogen was flowed over the hot tungsten wire (≈2000° C.). However, no excess power was observed when helium was flowed over the hot tungsten wire or when hydrogen was flowed over the hot tungsten wire with no MoI_2 present in the cell. Rates of heat production were reproducibly observed which were higher than that expected from the conversion of all the hydrogen inside the cell to water, and the total energy observed was over 30 times larger than that expected if all the catalytic material in the cell were converted to the lowest energy state by "known" chemical reactions. Thus, "anomalous" heat, heat of a magnitude and duration which could not be explained by conventional chemistry, was reproducibly observed.

The gaseous contents of the reactor were monitored with a mass spectrometer. At the time that excess energy was produced corresponding to the case wherein hydrogen was flowed over the hot filament, a higher ionizing mass two species was observable; whereas, during the control run wherein hydrogen was flowed over the hot tungsten wire with no MoI_2 present in the cell, a higher ionizing mass two species was not observed. The higher ionizing mass two species is was assigned to the dihydrino molecule,

$$2\mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow \mathrm{H}_2^*\left[2c' = \frac{\sqrt{2}\,a_o}{p}\right].$$

We claim:

1. A cell for extracting energy from hydrogen atoms comprising:

a reaction vessel containing

gaseous hydrogen atoms; and

a gaseous catalyst having a net enthalpy of reaction of about 27*(p/2) eV, where p is an integer greater than 1.

2. A cell according to claim **1**, wherein said gaseous catalyst comprises hydrogen atoms having a binding energy of about $E_b = 13.6/n^2$ eV, where n is a fraction whose numerator is **1** and denominator is an integer greater than 1.

3. A cell according to claim **1**, wherein said cell is constructed and arranged to be capable of maintaining the reaction,

$$m \times 27.21\ \mathrm{eV} + \mathrm{H}\left[\frac{a_H}{m'}\right] + \mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow$$

$$\mathrm{H}^+ + e^- + \mathrm{H}\left[\frac{a_H}{(p+m)}\right] + [(p+m)^2 - p^2 - (m'^2 - 2m)] \times 13.6\ \mathrm{eV}$$

$$\mathrm{H}^+ + e^- \rightarrow \mathrm{H}\left[\frac{a_H}{1}\right] + 13.6\ \mathrm{eV}$$

$$\mathrm{H}\left[\frac{a_H}{m'}\right] + \mathrm{H}\left[\frac{a_H}{p}\right] \rightarrow$$

$$\mathrm{H}\left[\frac{a_H}{1}\right] + \mathrm{H}\left[\frac{a_H}{(p+m)}\right] + [2pm + m^2 - m'^2] \times 13.6\ \mathrm{eV} + 13.6\ \mathrm{eV}$$

where m and p are positive non-zero integers, m' is an integer greater than 1, and a_H is the radius of the hydrogen atom (n=1).

4. A cell according to claim **1**, further comprising a source of hydrogen atoms including molecules containing hydrogen atoms, and a second catalyst for disassociating said molecules to produce hydrogen atoms.

5. A cell according to claim **4**, wherein said second catalyst comprises at least one element selected from the group consisting of transition elements, inner transition elements, precious metals, refractory metals, lanthanides, actinides, and activated charcoal.

6. A cell according to claim **4**, wherein said second catalyst is at least one element selected from the group consisting of the refractory metals, activated charcoal, platinum, palladium, gold, rhenium and iridium.

7. A cell according to claim **4**, further comprising a valve for controlling the flow of said molecules over said second catalyst.

8. A cell according to claim **1**, wherein said gaseous catalyst is formed from a source of gaseous catalyst which is adapted to sublime, boil, or volatize when heated.

9. A cell according to claim **1**, wherein said gaseous catalyst is formed from a salt.

10. A cell according to claim **9**, wherein said salt is selected from the group consisting of halides, sulfates, phosphates, carbonates, hydroxides, and sulfides.

11. A cell according to claim **9**, wherein said gaseous catalyst is formed from a salt of rubidium or potassium.

12. A cell according to claim **11**, wherein said salt of potassium is selected from the group consisting of KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4, K_2CO_3, K_2PO_4, and K_2GeF_4.

13. A cell according to claim **11**, wherein said salt of rubidium is selected from the group consisting of RbF, RbCl, RbBr, RbI, Rb_2S_2, RbOH, Rb_2SO_4, Rb_2CO_3, and Rb_3PO_4.

14. A cell according to claim **1**, wherein said gaseous catalyst comprises a cation having a vapor pressure greater than zero when said gaseous catalyst is heated, said cation being selected from the group consisting of (K^+), (Rb^+), (Mo^{2+}), and (Ti^{2+}).

15. A cell according to claim **1**, wherein said gaseous catalyst comprises a pair of cations having a vapor pressure greater than zero when said gaseous catalyst is heated, said pair of cations being selected from the group consisting of: (Sn^{4+}, Si^{4+}), (Pr^{3+}, Ca^{2+}), (Sr^{2+}, Cr^{2+}), (Cr^{3+}, Tb^{3+}), (Sb^{3+}, Co^{2+}), (Bi^{3+}, Ni^{2+}), (Pd^{2+}, In^+), (La^{3+}, Dy^{3+}), (La^{3+}, Ho^{3+}), (K^+, K^+), (V^{3+}, Pd^{2+}), (Lu^{3+}, Zn^{2+}), (As^{3+}, Ho^{3+}), (Mo^{5+}, Sn^{4+}), (Sb^{3+}, Cd^{2+}), (Ag^{2+}, Ag^+), (La^{3+}, Er^{3+}), (V^{4+}, B^{3+}), (Fe^{3+}, Ti^{3+}), (Co^{2+}, Ti^+), (Bi^{3+}, Zn^{2+}), (As^{3+}, Dy^{3+}), (Ho^{3+}, Mg^{2+}), (K^+, Rb^+), (Cr^{3+}, Pr^{3+}), (Sr^{2+}, Fe^{2+}), (Ni^{2+}, Cu^+), (Sr^{2+}, Mo^{2+}), (Y^{3+}, Zr^{4+}), (Cd^{2+}, Ba^{2+}), (Ho^{3+}, Pb^{2+}), (Pd^{2+}, Li^+), $Eu^{3+}, Mg^{2+})$, (Er^{3+}, Mg^{2+}), (Bi^{4+}, Al^{3+}), (Ca^{2+}, Sm^{3+}), (V^{3+}, La^{3+}), (Gd^{3+}, Cr^{2+}), (Mn^{2+}, Tl^+), (Yb^{3+}, Fe^{2+}), (Ni^{2+}, Ag^+), (Zn^{2+}, Yb^{2+}), (Se^{4+}, Sn^{4+}), (Sb^{3+}, Bi^{2+}), and (Eu^{3+}, Pb^{2+}).

16. A cell according to claim **1**, wherein said gaseous catalyst comprises an ionic compound resistant to reduction by hydrogen atoms.

17. A cell according to claim **1**, wherein said gaseous catalyst is adapted to provide ions.

18. A cell according to claim **1**, wherein said vessel includes temperature controlling structure capable of maintaining an atomic hydrogen partial pressure of less than about 1 torr.

19. A cell according to claim **1**, wherein said vessel includes temperature controlling structure capable of maintaining said catalyst in molten form.

20. A cell according to claim **1**, wherein said vessel includes temperature controlling structure capable of maintaining the temperature of said vessel at about 50° C. above the melting point of said gaseous catalyst.

21. A cell according to claim **1**, wherein said vessel is constructed and arranged to be capable of maintaining the hydrogen partial pressure in said vessel at about 200 millitorr.

22. A cell according to claim **15**, wherein said vessel includes temperature controlling structure capable of maintaining the temperature of said vessel at about 500° C. above the melting point of the compound having the highest melting point of a plurality of compounds which comprise a source of said gaseous catalyst.

23. A cell according to claim **1**, further comprising a valve for releasing said catalyst from said vessel.

24. A cell according to claim **1**, further comprising a valve for releasing said hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1.

25. A cell according to claim **1**, wherein said vessel includes temperature controlling structure to control a temperature of said vessel.

26. A cell according to claim **1**, further comprising a heater for heating said vessel.

27. A cell according to claim **1**, further comprising a catalyst reservoir communicating with said reaction vessel, said catalyst reservoir containing said gaseous catalyst or a source of gaseous catalyst.

28. A cell according to claim **27**, further comprising a heater for heating said catalyst.

29. A cell according to claim **27**, wherein said catalyst reservoir is external to said reaction vessel.

30. A cell according to claim **29**, further comprising a flow control valve for controlling the flow of said catalyst from said catalyst reservoir into said vessel.

31. A cell according to claim **1**, further comprising a chamber for containing hydrogen atoms or a source of hydrogen atoms communicating with said reaction vessel.

32. A cell according to claim **31**, further comprising a flow control valve for controlling the flow of hydrogen atoms from said chamber into said vessel.

33. A cell according to claim **31** wherein said source of hydrogen atoms comprises an internal combustion engine.

34. A cell according to claim **31**, wherein said source of hydrogen atoms comprises a tungsten capillary constructed and arranged to be heated for dissociating molecules containing hydrogen atoms to produce said gaseous hydrogen atoms.

35. A cell according to claim **34**, further comprising a valve for controlling the flow of said molecules over said tungsten capillary.

36. A cell according to claim **31**, wherein said source of hydrogen atoms comprises an inductively coupled plasma flow tube for dissociating molecules containing hydrogen atoms to produce hydrogen atoms.

37. A cell according to claim **36**, further comprising a valve for controlling the flow of said molecules into said inductively coupled plasma flow tube.

38. A cell according to claim **36**, further comprising a power controller for controlling the power dissipated in said inductively coupled plasma flow tube.

39. A cell according to claim **1**, further comprising a heat exchanger for removing said extracted power from said cell.

40. A cell according to claim **1**, further comprising a power gauge for measuring the amount of extracted power in said cell.

41. A cell according to claim **1**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to hydrogen reduction and which is adapted to sublime, boil or become volatile when heated.

42. A cell according to claim **1**, wherein said source of gaseous catalyst comprises an ionic compound which is adapted to sublime, boil or become volatile when heated.

43. A cell according to claim **1**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to thermal degradation.

44. A cell according to claim **1**, wherein said gaseous catalyst is formed from at least one metal selected from the group consisting of Mo, Ti, and Rb.

45. A cell according to claim **1**, wherein said gaseous catalyst is formed from at least one salt selected from the group consisting of Mol_2, $TiCl_2$, $TiCl_4$, $SnCl_4$, $SiCl_4$, $PrBr_3$, $CaBr_2$, $SrCl_2$, Crl_2, Tbl_3, $SbCl_3$, CrF_3, $CoCl_2$, $BiCl_3$, $NiCl_2$, PdF_2, InCl, $LaCl_3$, $DyCl_3$, Lal_3, Hol_3, VF_3, PbF_2, VOCl, Pbl_2, $LuCl_3$, $PbCl_2$, Asl_3, Hol_3, $MoCl_5$, $SnCl_4$, Sbl_3, Cdl_2, AgF_2, AgF, Lal_3, Erl_3, VCl_4, BCl_3, $FeCl_3$, $TiCl_3$, Col_2, CoF_2, Tll, TlF, $BiBr_3$, $ZnBr_2$, Asl_3, Dyl_3, $HOCl_3$, $MgCl_2$, $CrCl_3$, $PrCl_3$, $SrCl_2$, $FeCl_2$, $NiCl_2$, CuCl, $SrCl_2$, $MoCl_2$, YCl_3, $ZrCl_4$, Cdl_2, Bal_2, Hol_3, Pbl_2, PdF_2, LiF, $EuCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $BiCl_4$, $AlCl_3$, $CaBr_2$, $SmBr_3$, VaF_3, $LaCl_3$, Gdl_3, Crl_2, Mnl_2, $YbBr_3$, $FeBr_2$, $NiCl_2$, AgCl, $ZnCl_2$, $YbCl_2$, SeF_4, $SnCl_4$, SnF_4, Sbl_3, Bil_2, EuF_3, and $PbCl_2$.

46. A cell according to claim **1**, wherein said catalyst comprises potassium and has a net enthalpy of reaction of 27.28 eV.

47. A cell according to claim **1**, wherein said catalyst has a net enthalpy of reaction of about 27.2 eV.

48. A cell according to claim **1**, wherein said cell comprises a source of said gaseous catalyst combined with at least one of a hydrocarbon or water disposed such that said gaseous catalyst and said gaseous hydrogen atoms are capable being formed during combustion.

49. A cell according to claim **1**, further comprising a means for converting a source of catalyst to said gaseous catalyst.

50. A cell according to claim **49**, wherein said means for converting said source of catalyst to said gaseous catalyst comprises at least one of heat, electron-beam energy, photon energy, acoustic energy, electric field, or magnetic field.

51. A cell according to claim **1**, further comprising a filament coated with a source of gaseous catalyst.

52. A cell according to claim **1**, further comprising a source of gaseous hydrogen atoms is selected from the group consisting of hydrogen gas, water, hydrides, metal-hydrogen solutions, and hydrocarbons.

53. A cell according to claim **52**, further comprising means to disassociate water to form gaseous hydrogen atoms.

54. A cell according to claim **1**, further comprising a hot filament and a hydrogen containing gas stream.

55. A cell according to claim **1**, further comprising a hot grid and a hydrogen containing gas stream.

56. A cell according to claim **1**, further comprising a heated tungsten capillary and a hydrogen containing gas stream.

57. A cell according to claim **1**, further comprising a hydride maintained under nonequilibrium conditions.

58. A cell according to claim **1**, further comprising an inductively coupled plasma flow tube and a hydrogen gas containing stream.

59. A cell according to claim **1**, further comprising means to reform hydrocarbons to at least one of gaseous molecular and gaseous atomic hydrogen.

60. A cell according to claim **4**, wherein said second catalyst is treated with an aqueous solution of K_2CO_3 and H_2O_2.

61. A cell according to claim **4**, further comprising a temperature controlling structure capable of maintaining a selected atomic hydrogen partial pressure by controlling the temperature of said second catalyst.

62. A cell according to claim **61**, wherein said temperature controlling structure is at least one selected from the group consisting of an internal heater, an external heater, the catalysis of hydrogen, and a heat exchanger which removes energy from the cell.

63. A cell according to claim **1**, further comprising a source of UV light for disassociating hydrogen containing molecules to form said gaseous hydrogen atoms.

64. A cell according to claim **1**, further comprising a means for pyrolysis of hydrocarbons or water to form said gaseous hydrogen atoms.

65. A cell according to claim **4**, wherein said second catalyst comprises at least one selected from the group consisting of an element, compound, alloy or mixture of transition elements, inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal, and intercalated Cs carbon.

66. A cell according to claim **4**, further comprising a heater to heat said second catalyst.

67. A cell according to claim **4**, further comprising a filament or grid constructed and arranged to dissociate hydrogen and to heat said second catalyst.

68. A cell according to claim **4**, further comprising means for controlling the power output of said cell.

69. A cell according to claim **68**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of said second catalyst.

70. A cell according to claim **69**, wherein said means for controlling the temperature of said second catalyst comprises a filament or grid.

71. A cell according to claim **31**, further comprising a flow control means for controlling the flow of a source of gaseous hydrogen atoms or said gaseous hydrogen atoms from said chamber to said reaction vessel.

72. A cell according to claim **1**, further comprising a flow control means for controlling the flow of hydrogen from said reaction vessel.

73. A cell according to claim **71**, wherein said flow control means comprises a valve.

74. A cell according to claim **1**, further comprising a vacuum pump constructed and arranged for controlling the flow of hydrogen from said reaction vessel.

75. A cell according to claim **27**, further comprising a flow control means for controlling the flow of catalyst from said catalyst reservoir to said reaction vessel.

76. A cell according claim **1**, further comprising means for controlling the flow of said gaseous catalyst from said reaction vessel.

77. A cell according to claim **76**, wherein said means for controlling the flow of said gaseous catalyst from said reaction vessel comprises a valve.

78. A cell according to claim **1**, further comprising a vacuum pump constructed and arranged for controlling the flow of said gaseous catalyst from said reaction vessel.

79. A cell according to claim **1**, further comprising a nonreactive gas.

80. A cell according to claim **1**, further comprising a means for controlling the amount of a nonreactive gas in said reaction vessel.

81. A cell according to claim **1**, further comprising flow control means for controlling the flow of a nonreactive gas into said reaction vessel.

82. A cell according to claim **81**, wherein said means for controlling the amount of nonreactive gas in said vessel comprises a valve constructed and arranged to regulate the flow of said nonreactive gas into said reaction vessel.

83. A cell according to claim **1**, further comprising at least one of a valve or pump constructed and arranged for controlling the flow of a nonreactive gas from said reaction vessel.

84. A cell according to claim **1**, further comprising a pump in communication with said reaction vessel.

85. A cell according to claim **1**, further comprising structure for controlling the vapor pressure of said catalyst.

86. A cell according to claim **85**, wherein said structure for controlling the vapor pressure of said catalyst comprises a heater constructed and arranged to control the temperature of said reaction vessel.

87. A cell according to claim **1**, further comprising structure for maintaining a selected vapor pressure of said gaseous catalyst or source of said gaseous catalyst.

88. A cell according to claim **1**, further comprising structure for maintaining a selected vapor pressure of said gaseous catalyst or source of gaseous catalyst.

89. A cell according to claim **88**, wherein said structure for maintaining a selected vapor pressure of said gaseous catalyst or source of gaseous catalyst comprises a valve constructed and arranged for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir and a valve constructed and arranged for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said reaction vessel.

90. A cell according to claim **88**, wherein said structure for maintaining a selected vapor pressure of said source of gaseous catalyst or said gaseous catalyst comprises a valve constructed and arranged for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said reaction vessel.

91. A cell according to claim **1**, further comprising a valve for releasing hydrogen atoms having a binding energy of about E_b=13.6/n^2 eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1 or a compound containing said hydrogen atoms from said reaction vessel.

92. A cell according to claim **1**, further comprising means for adsorbing energy released from said hydrogen atom.

93. A cell according to claim **1**, wherein said vessel comprises an internal combustion chamber.

94. A cell according to claim **93**, wherein said internal combustion chamber is an engine cylinder.

95. A cell according to claim **1**, further comprising means for controlling the power output of said cell.

96. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the amount of said gaseous catalyst.

97. A cell according to claim **96**, wherein said means for controlling the amount of gaseous catalyst comprises means for controlling the temperature of said vessel and said gaseous catalyst is selected to have a vapor pressure dependent upon the temperature of said reaction vessel.

98. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the flow of a source of gaseous catalyst or gaseous catalyst from said reaction vessel.

99. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of a source of catalyst.

100. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the amount of said gaseous hydrogen atoms or a source of gaseous hydrogen atoms in said vessel.

101. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the flow of gaseous hydrogen atoms or source of said hydrogen atoms into said reaction vessel.

102. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the flow of gaseous hydrogen atoms or source of said hydrogen atoms from said reaction vessel.

103. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises controlling the amount of said nonreactive gas present in said reaction vessel.

104. A cell according to claim **103**, wherein said means for controlling the amount of nonreactive gas comprises means for controlling the flow of said nonreactive gas into said reaction vessel.

105. A cell according to claim **103**, wherein said means for controlling the amount of nonreactive gas comprises means for controlling the flow of said nonreactive gas from said reaction vessel.

106. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the flow of a hydrogen containing gas over at least one of a hot filament, a tungsten capillary heated by electron bombardment, or an inductively coupled plasma flow.

107. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the power dissipated in an inductively coupled plasma flow tube.

108. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the power dissipated in a hot filament, grid, or tungsten capillary heated by electron bombardment.

109. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of a hot filament, grid or tungsten capillary heated by electron bombardment over which a hydrogen containing gas flows.

110. A cell according to claim **95**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of a hydride maintained under nonequilibrium conditions.

111. A cell according to claim **27**, further comprising means for controlling the power output of said cell.

112. A cell according to claim **111**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of said catalyst reservoir and said gaseous catalyst is selected to have a vapor pressure dependent upon the temperature of said catalyst reservoir.

113. A cell according to claim **111**, wherein said means for controlling the power output of said cell comprises means for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir into said reaction vessel.

114. A cell according to claim **1**, further comprising a boat contained within said reaction chamber, said boat containing a source of gaseous catalyst or said gaseous catalyst.

115. A cell according to claim **114**, further comprising a means for controlling the power of said cell.

116. A cell according to claim **114**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of said boat and said gaseous catalyst is selected to have a vapor pressure dependent upon the temperature of said boat.

117. A cell according to claim **27**, further comprising means for measuring the temperature of said catalyst reservoir.

118. A cell according to claim **114**, further comprising means for measuring the temperature of said boat.

119. A cell according to claim **27**, further comprising a means for measuring the temperature of said source of said gaseous catalyst contained in said catalyst reservoir.

120. A cell according to claim **114**, further comprising a means for measuring the temperature of said source of said gaseous catalyst contained in said boat.

121. A cell according to claim **1**, further comprising means for measuring the temperature of said reaction vessel.

122. A cell according to claim **1**, further comprising means for measuring the temperature of a source of said gaseous hydrogen atoms.

123. A cell according to claim **4**, further comprising means for measuring the temperature said second catalyst.

124. A cell according to claim **1**, further comprising means to measure the cell temperature.

125. A cell according to claim **124**, further comprising temperature controlling structure constructed and arranged to maintain a temperature in said reaction vessel greater than a temperature in said catalyst reservoir.

126. A cell according to claim **114**, further comprising temperature controlling structure constructed and arranged to maintain a temperature in said reaction vessel greater than a temperature in said boat.

127. A cell according to claim **1**, further comprising temperature controlling structure for maintaining a selected temperature of said reaction vessel.

128. A cell according to claim **1**, further comprising a nebulizer or atomizer.

129. A cell according to claim **1**, further comprising means to measure the pressure in said reaction vessel.

130. A cell according to claim **1**, further comprising means to measure the hydrogen pressure in said reaction vessel.

131. A cell according to claim **1**, further comprising means to measure the gaseous catalyst pressure in said reaction vessel.

132. A cell according to claim **1**, wherein said vessel is capable of containing a pressure within the range of 10^{-3} atmospheres to 100 atmospheres.

133. A cell according to claim **1**, further comprising a vacuum pump in communication with said vessel and said vessel being constructed and arranged to contain pressures less than atmospheric.

134. A cell according to claim **27**, further comprising a temperature controlling structure capable of maintaining a temperature in the said reaction vessel that is greater than a temperature of said catalyst reservoir.

135. A cell according to claim **27**, further comprising temperature controlling structure capable of maintaining said source of gaseous catalyst in a molten form.

136. A cell according to claim **114**, further comprising temperature controlling structure capable of maintaining said source of gaseous catalyst in a molten form.

137. A cell according to claim **27**, further comprising temperature controlling structure capable of maintaining the temperature of said catalyst reservoir at about 50° C. above the melting point of said gaseous catalyst.

138. A cell according to claim **1**, further comprising temperature controlling structure capable of maintaining the temperature of said reaction vessel at about 50° C. above the melting point of a source of gaseous catalyst.

139. A cell according to claim **114**, further comprising temperature controlling structure capable of maintaining the temperature of said boat at about 50° C. above the melting point of said gaseous catalyst.

140. A cell according to claim **15**, further comprising a catalyst reservoir in communication with said reaction vessel and temperature controlling structure capable of maintaining the temperature of said catalyst reservoir at about 50° C. above the melting point of the compound having the highest melting point of a plurality of compounds which comprise said source of gaseous catalyst.

141. A cell according to claim **15**, further comprising a boat contained in said reaction vessel and temperature controlling structure capable of maintaining the temperature of said boat at about 50° C. above the melting point of the compound having the highest melting point of a plurality of compounds which comprise said source of gaseous catalyst.

142. A cell according to claim **27**, further comprising temperature controlling structure capable of maintaining the temperature of said reaction vessel at about 50° C. above the melting point of said gaseous catalyst.

143. A cell according to claim **15**, further comprising a catalyst reservoir containing said source of gaseous catalyst and being in communication with said reaction vessel, and temperature controlling structure capable of maintaining the temperature of said reaction vessel at about 50° C. above the melting point of the compound having the highest melting point of a plurality of compounds which comprise said source of gaseous catalyst.

144. A cell according to claim **15**, further comprising a boat containing said source of gaseous catalyst and being disposed in said reaction vessel, and temperature controlling structure capable of maintaining the temperature of said reaction vessel at about 50° C. above the melting point of the compound having the highest melting point of a plurality of compounds which comprise said source of gaseous catalyst.

145. A method for extracting energy from hydrogen atoms comprising the steps of:

providing a gaseous catalyst having a net enthalpy of reaction of about 27*(p/2) eV, where p is an integer greater than 1;

providing gaseous hydrogen atoms; and

reacting said gaseous catalyst with said gaseous hydrogen atoms, thereby releasing energy from said gaseous hydrogen atoms.

146. A method according to claim **145**, wherein said gaseous hydrogen atoms are provided by disassociating molecules containing hydrogen atoms.

147. A method according to claim **145**, wherein gaseous hydrogen atoms are

provided by contacting molecules containing hydrogen atoms with a second catalyst for disassociating said molecules to produce hydrogen atoms in the gas phase.

148. A method according to claim **145**, wherein said gaseous catalyst comprises gaseous hydrogen atoms having a binding energy of about E_b=13.6/n^2 eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1.

149. A method according to claim **145**, wherein said gaseous catalyst is provided according to the reaction,

$$m \times 27.21\text{ eV} + \mathrm{H}\left[\frac{a_H}{m'}\right] + \mathrm{H}\left[\frac{a_H}{p}\right] \to$$

$$\mathrm{H}^+ + e^- + \mathrm{H}\left[\frac{a_H}{(p+m)}\right] + [(p+m)^2 - p^2 - (m'^2 - 2m)] \times 13.6\text{ eV}$$

$$\mathrm{H}^+ + e^- \to \mathrm{H}\left[\frac{a_H}{1}\right] + 13.6\text{ eV}$$

$$\mathrm{H}\left[\frac{a_H}{m'}\right] + \mathrm{H}\left[\frac{a_H}{p}\right] \to$$

$$\mathrm{H}\left[\frac{a_H}{1}\right] + \mathrm{H}\left[\frac{a_H}{(p+m)}\right] + [2pm + m^2 - m'^2] \times 13.6\text{ eV} + 13.6\text{ eV}$$

where m and p are positive non-zero integers, m' is an integer greater than 1, and a_H is the radius of the hydrogen atom (n=1).

150. A method according to claim **145**, wherein said gaseous catalyst is provided by volatizing a material to a gaseous state and ionizing said gaseous material.

151. A method according to claim **145**, wherein said hydrogen atoms are provided by flowing gaseous molecules containing hydrogen atoms over a hot refractory metal, transition metal, platinum, palladium, gold, rhenium, or iridium.

152. A method according to claim **145**, wherein said hydrogen atoms are provided by flowing gaseous molecules containing hydrogen atoms over a tungsten capillary heated by electron bombardment to between 1800 and 2000 K.

153. A method according to claim **145**, wherein said hydrogen atoms are provided by flowing gaseous molecules containing hydrogen atoms in an inductively coupled plasma flow tube.

154. A method according to claim **145**, wherein said reaction occurs at a pressure less than about one torr.

155. A method according to claim **145**, wherein the partial pressure of hydrogen atoms in the reaction is less than about one torr.

156. A method according to claim **145**, wherein the partial pressure of hydrogen atoms in the reaction is about 200 millitorr.

157. A method according to claim **145**, wherein said reaction occurs at a temperature of about 50° C. above the melting point of said gaseous catalyst.

158. A method according to claim **145**, wherein the vapor partial pressure of said gaseous catalyst is controlled by varying the temperature of said gaseous catalyst.

159. A method according to claim **145**, further comprising a step of isolating produced hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1.

160. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising an ionic compound which is resistant to hydrogen reduction.

161. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising an ionic compound which is resistant to hydrogen reduction and which is adapted to sublime, boil or become volatile when heated.

162. A method according to claim **145**, further comprising the step of forming said gaseous compound from a source of gaseous catalyst comprising an ionic compound which is adapted to sublime, boil or become volatile when heated.

163. A method according to claim **145**, further comprising the step of forming said gaseous compound from a source of gaseous catalyst comprising an ionic compound which is resistant to thermal degradation.

164. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising a salt of rubidium or potassium.

165. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising a salt that can form a vapor comprising ions when heated.

166. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising a salt of rubidium selected from the group consisting of RbF, RbCl, RbBr, RbI, Rb_2S_2, RbOH, Rb_2SO_4, Rb_2CO_3, and Rb_3PO_4.

167. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising a salt of potassium selected from the group consisting of KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4, K_2CO_3, K_3PO_4, and K_2GeF_4.

168. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising at least one metal selected from the group consisting of Mo, Ti, and Rb.

169. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from a source of gaseous catalyst comprising at least one salt selected from the group consisting of MoI_2, $TiCl_2$, $TiCl_4$, $SnCl_4$, $SiCl_4$, $PrBr_3$, $CaBr_2$, $SrCl_2$, CrI_2, TbI_3, $SbCl_3$, CrF_3, $CoCl_2$, $BiCl_3$, $NiCl_2$, PdF_2, InCl, $LaCl_3$, $DyCl_3$, LaI_3, HoI_3, KNO_3, VF_3, PbF_2, VOCl, PbI_2, $LuCl_3$, $PbCl_2$, AsI_3, HoI_3, $MoCl_5$, $SnCl_4$, SbI_3, CdI_2, AgF_2, AgF, LaI_3, ErI_3, VCl_4, BCl_3, $FeCl_3$, $TiCl_3$, CoI_2, CoF_2, TlI, TlF, $BiBr_3$, $ZnBr_2$, AsI_3, DyI_3, $HoCl_3$, $MgCl_2$, $CrCl_3$, $PrCl_3$, $SrCl_2$, $FeCl_2$, $NiCl_2$, CuCl, $SrCl_2$, $MoCl_2$, YCl_3, $ZrCl_4$, CdI_2, BaI_2, HoI_3, PbI_2, PdF_2, LiF, $EuCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $BiCl_4$, $AlCl_3$, $CaBr_2$, $SmBr_3$, VaF_3, $LaCl_3$, GdI_3, CrI_2, MnI_2, $YbBr_3$, $FeBr_2$, $NiCl_2$, AgCl, $ZnCl_2$, $YbCl_2$, SeF_4, $SnCl_4$, SnF_4, SbI_3, BiI_2, EuF_3, and $PbCl_2$.

170. A method according to claim **145**, wherein said gaseous catalyst comprises at least one ion selected from the group consisting of Mo^{2+}, Ti^{2+}, and Rb^+.

171. A method according to claim **145**, wherein said gaseous catalyst comprises at least one pair of ions selected from the group consisting of: (Sn^{4+}, Si^{4+}), (Pr^{3+}, Ca^{2+}), (Sr^{2+}, Cr^{2+}), (Cr^{3+}, Tb^{3+}), (Sb^{3+}, Co^{2+}), (Bi^{3+}, Ni^{2+}), (Pd^{2+}, In^+), (La^{3+}, Dy^{3+}), (La^{3+}, Ho^{3+}), (K^+, K^+), (V^{3+}, Pd^{2+}), (Lu^{3+}, Zn^{2+}), (As^{3+}, Ho^{3+}), (Mo^{5+}, Sn^{4+}), (Sb^{3+}, Cd^{2+}), (Ag^{2+}, Ag^+), (La^{3+}, Er^{3+}), (V^{4+}, B^{3+}), (Fe^{3+}, Ti^{3+}), (Co^{2+}, Ti^+), (Bi^{3+}, Zn^{2+}), (As^{3+}, Dy^{3+}), (Ho^{3+}, Mg^{2+}), (K^+, Rb^+), (Cr^{3+}, Pr^+), (Sr^{2+}, Fe^{2+}), (Ni^{2+}, Cu^+), (Sr^{2+}, Mo^{2+}), (Y^{3+}, Zr^{4+}), (Cd^{2+}, Ba^{2+}), (Ho^{3+}, Pb^{2+}), (Pb^{2+}, Li^+), (Eu^{3+}, Mg^{2+}), (Er^{3+}, Mg^{2+}), (Bi^{4+}, Al^{3+}), (Ca^{2+}, Sm^{3+}), (V^{3+}, La^{3+}), (Gd^{3+}, Cr^{2+}), (Mn^{2+}, Ti^+), (Yb^{3+}, Fe^{2+}), (Ni^{2+}, Ag^+), (Zn^{2+}, Yb^{2+}), (Se^{4+}, Sn^{4+}), (Sb^{3+}, Bi^{2+}), and (Eu^{3+}, Pb^{2+}).

172. A method according to claim **145**, further comprising the step of forming said gaseous catalyst from a source of gaseous catalyst comprising a salt of one or more cations and at least one anion selected from the group consisting of halides, sulfates, phosphates, carbonates, hydroxide and sulfides.

173. A method according to claim **145**, wherein said gaseous catalyst is selected to have a resonant adsorption with the energy released from said gaseous hydrogen atoms undergoing a transition to a lower energy state.

174. A method according to claim **145**, wherein said gaseous catalyst comprises potassium and has a net enthalpy of reaction of 27.28 eV.

175. A method according to claim **145**, wherein said gaseous catalyst has a net enthalpy of reaction of about 27.2 eV.

176. A method according to claim **145**, further comprising the step of combining a source of gaseous catalyst with a source of gaseous hydrogen atoms comprising at least one of a hydrocarbon or water, and providing combustion which volatizes said source of gaseous catalyst to form said gaseous catalyst and provide said gaseous hydrogen atoms.

177. A method according to claim **145**, further comprising the step of forming a source of gaseous catalyst or said gaseous catalyst in situ.

178. A method according to claim **177**, wherein said step of forming said source of gaseous catalyst or said gaseous catalyst in situ comprises the ionization of a reactant.

179. A method according to claim **178**, wherein said step of ionization comprises thermal ionization of said reactant.

180. A method according to claim **178**, wherein said step of ionization comprises chemical ionization of said reactant.

181. A method according to claim **180**, wherein said step of chemical ionization comprises oxidation or reduction of said reactant.

182. A method according to claim **145**, further comprising the step of volatizing a source of catalyst to form said gaseous catalyst utilizing energy from at least one of heat, electron-beam energy, photon energy, acoustic energy, electric field, or magnetic field.

183. A method according to claim **145**, wherein said the step of volatizing a source of catalyst comprises the step of heating a filament coated with said source of gaseous catalyst.

184. A method according to claim **145**, further comprising adding a source of catalyst to said reaction vessel and heating said source of catalyst to form said gaseous catalyst.

185. A method according to claim **145**, further comprising the step of providing a source of catalyst in a catalyst reservoir comprising a container separate from said vessel and said container communicates with said reaction vessel.

186. A method according to claim **145**, further comprising the step of providing a source of catalyst in a boat contained within said reaction vessel.

187. A method according to claim **145**, wherein said step of providing hydrogen atoms comprises the steps of disassociating a hydrogen containing compound into hydrogen atoms.

188. A method according to claim **145**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas over a hot filament.

189. A method according to claim **145**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas over a hot grid.

190. A method according to claim **145**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas through a tungsten capillary heated by electron bombardment.

191. A method according to claim **145**, wherein said step of providing hydrogen atoms comprises the steps of maintaining a hydride under nonequilibrium conditions.

192. A method according to claim **147**, wherein said second catalyst comprises at least one element selected from the group consisting of transition elements, inner transition elements, precious metals, refractory metals, lanthanides, actinides and activated charcoal.

193. A method according to claim **147**, wherein said second catalyst is selected from the group consisting of an element, compound, alloy or mixture of transition elements, inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal, and intercalated Cs carbon.

194. A method according to claim **147**, further comprising the step of utilizing a hot filament or hot grid to disassociate a hydrogen containing gas into gaseous hydrogen atoms and to heat said second catalyst.

195. A method according to claim **147**, further comprising the step of controlling the power output of said cell.

196. A method according to claim **147**, wherein said step of controlling the power output of said cell comprises controlling the temperature of said second catalyst.

197. A method according to claim **196**, wherein said step of controlling the temperature of said second catalyst comprises utilizing a heated filament or grid.

198. A method according to claim **145**, further comprising the step of forming said gaseous hydrogen atoms from at least one source of gaseous hydrogen atoms selected from the group consisting of hydrogen gas, water, hydrides, metal-hydrogen solutions, and hydrocarbons.

199. A method according to claim **145**, wherein said step of providing gaseous hydrogen atoms comprises pyrolyzing hydrocarbons or water.

200. A method according to claim **145**, further comprising the step of reforming hydrocarbons to at least one of gaseous molecular and gaseous atomic hydrogen.

201. A method according to claim **145**, further comprising the step of disassociating hydrogen containing molecules using UV light to form said gaseous hydrogen atoms.

202. A method according to claim **145**, further comprising the step of controlling the amount of gaseous hydrogen provided in said reaction vessel.

203. A method according to claim **145**, further comprising the step of controlling the flow of a source of gaseous hydrogen atoms or said gaseous hydrogen atoms from a chamber to said reaction vessel.

204. A method according to claim **145**, further comprising the step of utilizing a valve for controlling the flow of gaseous hydrogen or source of gaseous hydrogen from said reaction vessel.

205. A method according to claim **145**, further comprising the step of controlling the flow of gaseous hydrogen from said reaction vessel.

206. A method according to claim **145**, further comprising the step of utilizing a vacuum pump for controlling the flow of gaseous hydrogen from said reaction vessel.

207. A method according to claim **145**, further comprising the step of utilizing a valve for controlling the flow of gaseous hydrogen from a chamber into said reaction vessel.

208. A method according to claim **145**, further comprising controlling the partial pressure of said gaseous hydrogen atoms.

209. A method according to claim **145**, wherein a partial pressure of said gaseous hydrogen atoms or source of gaseous hydrogen atoms in said reaction vessel is maintained within the range of 10^{-3} atmospheres to 100 atmospheres.

210. A method according to claim **145**, further comprising controlling the amount of gaseous catalyst or a source of gaseous catalyst introduced into said reaction vessel.

211. A method according to claim **145**, further comprising controlling the flow of gaseous catalyst or a source of gaseous catalyst from a catalyst reservoir containing gaseous catalyst or a source of gaseous catalyst to said reaction vessel.

212. A method according to claim **145**, further comprising controlling the flow of gaseous catalyst or a source of gaseous catalyst from a boat containing gaseous catalyst or a source of gaseous catalyst.

213. A method according to claim **145**, further comprising the step of controlling the flow of said gaseous catalyst or a source of gaseous catalyst from said reaction vessel.

214. A method according to claim **145**, further comprising the step of controlling the vapor pressure of said gaseous catalyst or a source of gaseous catalyst in said reaction vessel.

215. A method according to claim **145**, wherein a vapor pressure of said gaseous catalyst or a source of gaseous catalyst is maintained at about 50 to 210 millitorr.

216. A method according to claim **145**, further comprising using a vacuum pump to control the flow of said gaseous catalyst or a source of gaseous catalyst from said reaction vessel.

217. A method according to claim **145**, further comprising using a valve to control the flow of a source of gaseous catalyst or a source of gaseous catalyst from a catalyst reservoir into said reaction vessel.

218. A method according to claim **145**, further comprising using a valve to control the flow of a source of gaseous catalyst or said catalyst from said reaction vessel.

219. A method according to claim **145**, further comprising the step of supplying a nonreactive gas to said reaction vessel.

220. A method according to claim **219**, further comprising the step of controlling the vapor pressure of said nonreactive gas in said reaction vessel.

221. A method according to claim **219**, further comprising the step of controlling the flow of said nonreactive gas supplied to said reaction vessel.

222. A method according to claim **219**, further comprising the step of controlling the amount of said nonreactive gas released from said reaction vessel.

223. A method according to claim **219**, further comprising utilizing a vacuum pump for controlling the flow of said nonreactive gas from said reaction vessel.

224. A method according to claim **219**, further comprising the step of utilizing a valve for controlling the flow of said nonreactive gas from said reaction vessel.

225. A method according to claim **219**, further comprising the step of utilizing a valve for controlling the flow of said nonreactive gas into said reaction vessel.

226. A method according to claim **145**, further comprising the step of controlling the vapor pressure of said gaseous catalyst in said reaction vessel.

227. A method according to claim **226**, wherein said step of controlling the vapor pressure of said gaseous catalyst comprises controlling the temperature in a catalyst reservoir containing a source of gaseous catalyst or said gaseous catalyst and being in communication with said reaction vessel, and controlling the flow of gaseous catalyst from said catalyst reservoir.

228. A method according to claim **226**, wherein said step of controlling the vapor pressure of said gaseous catalyst comprises controlling the temperature in a boat containing a source of gaseous catalyst or said gaseous catalyst and being contained in said reaction vessel, and controlling the flow of gaseous catalyst from said boat.

229. A method according to claim **145**, further comprising the step of controlling the temperature in a catalyst reservoir containing a source of gaseous catalyst or said gaseous catalyst and being in communication with said reaction vessel.

230. A method according to claim **145**, further comprising the step of controlling the temperature in a boat containing a source of gaseous catalyst or said gaseous catalyst and being contained in said reaction vessel.

231. A method according to claim **145**, wherein the reaction to provide a net enthalpy of about 27 (p/2) eV, where p is a positive integer greater than 1, comprises an electrochemical, chemical, photochemical, thermal, free radical, sonic, nuclear, inelastic photon, or particle scattering reaction, or mixtures thereof.

232. A method according to claim **145**, wherein a pressure in said reaction vessel is maintained within the range of 10^{-3} atmospheres to 100 atmospheres.

233. A method according to claim **145**, wherein said reaction occurring at a pressure less than atmospheric pressure.

234. A method according to claim **145**, further comprising the step of releasing hydrogen atoms from said reaction vessel having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1 or a compound containing said hydrogen atoms.

235. A method according to claim **145**, further comprising the step of adsorbing said released energy.

236. A method according to claim **145**, further comprising the step of converting energy released from said hydrogen atom into electrical energy.

237. A method according to claim **145**, wherein said reaction step is conducted in an internal combustion chamber.

238. A method according to claim **145**, wherein said internal combustion chamber is an engine cylinder.

239. A method according to claim **145**, further comprising the step of controlling the power output of said cell.

240. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the amount of said gaseous catalyst present in said reaction vessel.

241. A method according to claim **240**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the temperature of said reaction vessel and selecting said gaseous catalyst or source of gaseous catalyst to have a vapor pressure dependent upon the temperature of said reaction vessel.

242. A method according to claim **240**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the temperature of a catalyst reservoir containing a source of gaseous catalyst or said gaseous catalyst and being in communication with said reaction vessel, and selecting said gaseous catalyst to have a vapor pressure dependent upon the temperature of said catalyst reservoir.

243. A method according to claim **240**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir into said reaction vessel.

244. A method according to claim **240**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the flow of said source of gaseous catalyst or gaseous catalyst from said reaction vessel.

245. A method according to claim **240**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the temperature of a boat containing a source of gaseous catalyst or said gaseous catalyst and being contained in said reaction vessel, and selecting said gaseous catalyst to have a vapor pressure dependent upon the temperature of said boat.

246. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the amount of said gaseous hydrogen atoms present in said reaction vessel.

247. A method according to claim **246**, wherein said step of controlling the amount of said gaseous hydrogen atoms comprises controlling the flow of gaseous hydrogen atoms or source of gaseous hydrogen atoms into said reaction vessel.

248. A method according to claim **246**, wherein said step of controlling the amount of said source of gaseous hydrogen atoms or gaseous hydrogen atoms comprises controlling the flow of said source of gaseous hydrogen atoms or gaseous hydrogen atoms from said reaction vessel.

249. A method according to claim **246**, wherein said step of controlling the amount of said source of gaseous hydrogen atoms or gaseous hydrogen atoms comprises controlling the temperature of a second catalyst for dissociating a hydrogen containing compound into gaseous hydrogen atoms.

250. A method according to claim **249**, wherein said step of controlling the temperature of a second catalyst for dissociating a hydrogen containing compound into gaseous hydrogen atoms comprises controlling the power dissipated in a second catalyst heater.

251. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the amount of nonreactive gas in said reaction vessel.

252. A method according to claim **251**, wherein said step of controlling the amount of nonreactive gas in said reaction vessel comprises controlling the flow of nonreactive gas into said reaction vessel.

253. A method according to claim **252**, wherein said step of controlling the amount of nonreactive gas in said reaction vessel comprises controlling the flow of nonreactive gas from said reaction vessel.

254. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the temperature of a source of gaseous catalyst.

255. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the flow of a hydrogen containing gas over at least one of a hot filament, a tungsten capillary heated by electron bombardment, or an inductively coupled plasma flow.

256. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the power dissipated in an inductively coupled plasma flow tube, hot filament or grid, or tungsten capillary heated by electron bombardment.

257. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the temperature of a hot filament or tungsten capillary heated by electron bombardment over which a hydrogen containing gas flows.

258. A method according to claim **239**, wherein said step of controlling the power output of said cell comprises controlling the temperature of a hydride maintained under nonequilibrium conditions.

259. A method according to claim **145**, wherein a temperature in said reaction vessel is maintained at a higher temperature than in a catalyst reservoir in communication with said reaction vessel or a boat contained within said reaction vessel.

260. A method according to claim **145**, further comprising the step of measuring the temperature of a catalyst reservoir in communication with said reaction vessel or a boat contained in said reaction vessel.

261. A method according to claim **145**, further comprising the step of measuring the temperature of a source of said gaseous catalyst contained in a catalyst reservoir in communication with said reaction vessel or a boat contained within said reaction vessel.

262. A method according to claim **145**, further comprising the step of measuring the temperature of a chamber containing a source of said hydrogen atoms in communication with said reaction vessel.

263. A method according to claim **145**, further comprising the step of measuring the temperature of a source of said gaseous hydrogen atoms.

264. A method according to claim **147**, further comprising the step of measuring the temperature of said second catalyst.

265. A method according to claim **145**, further comprising the step of controlling the temperature of said reaction vessel.

266. A method according to claim **145**, further comprising utilizing a nebulizer or atomizer to form said gaseous catalyst.

267. A method according to claim **145**, further comprising the step of measuring the pressure in said reaction vessel.

268. A method according to claim **145**, further comprising the step of controlling the pressure in said reaction vessel.

269. A method according to claim **145**, further comprising the step of measuring the hydrogen pressure in said reaction vessel.

270. A method according to claim **145**, further comprising the step of measuring the gaseous catalyst pressure in said reaction vessel.

271. A method according to claim **145**, further comprising the step of converting energy released from said gaseous hydrogen atoms into electrical energy.

272. A method according to claim **145**, further comprising controlling the pressure of said gaseous catalyst by controlling the amount of said source of catalyst being added to said reaction vessel.

273. A cell for extracting energy from hydrogen atoms comprising:

a reaction vessel;

a source of gaseous hydrogen atoms; and

a source of a gaseous catalyst having a net enthalpy of reaction of about 27(p/2) eV, where p is an integer greater than 1.

274. A cell for extracting energy from hydrogen atoms comprising:

a reaction vessel;

a chamber communicating with said vessel, said chamber containing gaseous hydrogen atoms or a source of said hydrogen atoms; and

a catalyst reservoir communicating with said reaction vessel or a boat contained in said reaction vessel, said catalyst reservoir or boat containing a gaseous catalyst having a net enthalpy of reaction of about 27*(p/2) eV, where p is an integer greater than 1, or a source of said gaseous catalyst.

275. A cell according to claim **274**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to hydrogen reduction.

276. A cell according to claim **274**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to hydrogen reduction and which is adapted to sublime, boil or become volatile when heated.

277. A cell according to claim **274**, wherein said source of gaseous catalyst comprises an ionic compound which is adapted to sublime, boil or become volatile when heated.

278. A cell according to claim **274**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to thermal degradation.

279. A cell according to claim **274**, wherein said source of gaseous catalyst comprises a salt of rubidium or potassium.

280. A cell according to claim **274**, wherein said source of gaseous catalyst comprises a salt that can form a vapor comprising ions when heated.

281. A cell according to claim **274**, wherein said source of gaseous catalyst comprises a salt of rubidium selected from the group consisting of RbF, $RbCl$, $RbBr$, Rbl, Rb_2S_2, $RbOH$, Rb_2SO_4, Rb_2CO_3, and Rb_3PO_4.

282. A cell according to claim **274**, wherein said source of gaseous catalyst comprises a salt of potassium selected from the group consisting of KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4, K_2CO_3, K_3PO_4, and K_2GeF_4.

283. A cell according to claim **274**, wherein said source of gaseous catalyst comprises at least one metal selected from the group consisting of Mo, Ti, and Rb.

284. A cell according to claim **274**, wherein said source of gaseous catalyst comprises at least one salt selected from the group consisting of Mol_2, $TiCl_2$, $TiCl_4$, $SnCl_4$, $SiCl_4$, $PrBr_3$, $CaBr_2$, $SrCl_2$, Crl_2, Tbl_3, $SbCl_3$, CrF_3, $CoCl_2$, $BiCl_3$, $NiCl_2$, PdF_2, $InCl$, $LaCl_3$, $DyCl_3$, Lal_3, Hol_3, KNO_3, VF_3, PbF_2, $VOCl$, Pbl_2, $LuCl_3$, $PbCl_2$, Asl_3, Hol_3, $MoCl_5$, $SnCl_4$, Sbl_3, Cdl_2, AgF_2, AgF, Lal_3, Erl_3, VCl_4, BCl_3, $FeCl_3$, $TiCl_3$, Col_2, CoF_2, Tll, TlF, $BiBr_3$, $ZnBr_2$, Asl_3, Dyl_3, $HoCl_3$, $MgCl_2$, $CrCl_3$, $PrCl_3$, $SrCl_2$, $FeCl_2$, $NiCl_2$, $CuCl$, $SrCl_2$, $MoCl_2$, YCl_3, $ZrCl_4$, Cdl_2, Bal_2, Hol_3, Pbl_2, PdF_2, LiF, $EuCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $BiCl_4$, $AlCl_3$, $CaBr_2$, $SmBr_3$, VaF_3, $LaCl_3$, Gdl_3, Crl_2, Mnl_2, $YbBr_3$, $FeBr_2$, $NiCl_2$, $AgCl$, $ZnCl_2$, $YbCl_2$, SeF_4, $SnCl_4$, SnF_4, Sbl_3, Bil_2, EuF_3, and $PbCl_2$.

285. A cell according to claim **274**, wherein said gaseous catalyst comprises at least one ion selected from the group consisting of Mo^{2+}, Ti^{2+}, and Rb^{+}.

286. A cell according to claim **274**, wherein said gaseous catalyst comprises at least one pair of ions selected from the group consisting of: (Sn^{4+}, Si^{4+}), (Pr^{3+}, Ca^{2+}), (Sr^{2+}, Cr^{2+}), (Cr^{3+}, Tb^{3+}), (Sb^{3+},Co^{2+}), (Bi^{3+}, Ni^{2+}), (Pd^{2+}, In^{+}), (La^{3+}, Dy^{3+}, Ho^{3+}), K^{+}, K^{+}) , (V^{3+}, Pd^{2+}), (Lu^{3+}, Zn^{2+}), (As^{3+}, Ho^{3+}), (Mo^{5+}, Sn^{4+}), (Sb^{3+}, Cd^{2+}), (Ag^{2+}, Ag^{+}), (La^{3+}, Er^{3+}), (V^{4+}, B^{3+}), (Fe^{3+}, Ti^{3+}), (Co^{2+}, Ti^{+}), (Bi^{3+}, Zn^{2+}), (As^{3+}, Dy^{3+}), (Ho^{3+}, Mg^{2+}), (K^{+}, Rb^{+}), (Cr^{3+}, Pr^{3+}), (Sr^{2+}, Fe^{2+}), (Ni^{2+}, Cu^{+}), (Sr^{2+}, Mo^{2+}), (Y^{3+}, Zr^{4+}), (Cd^{2+}, Ba^{2+}),

(Ho^{3+}, Pb^{2+}), (Pb^{2+}, Li^{+}), (Eu^{3+}, Mg^{2+}), (Er^{3+}, Mg^{2+}), (Bi^{4+}, Al^{3+}), (Ca^{2+}, Sm^{3+}), (V^{3+}, La^{3+}), (Gd^{3+}, Cr^{2+}), (Mn^{2+}, Ti^{+}), (Yb^{3+}, Fe^{2+}), (Ni^{2+}, Ag^{+}), (Zn^{2+}, Yb^{2+}), $(Se^{4+}Sn^{4+})$, (Sb^{3+}, Bi^{2+}), and (Eu^{3+}, Pb^{2+}).

287. A cell according to claim **274**, wherein said source of gaseous catalyst comprises a salt of one or more cations and at least one anion selected from the group consisting of halides, sulfates, phosphates, carbonates, hydroxide and sulfides.

288. A cell according to claim **274**, wherein said gaseous catalyst comprises hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1.

289. A cell according to claim **274**, wherein said gaseous catalyst comprises potassium and has a net enthalpy of reaction of 27.28 eV.

290. A cell according to claim **274**, wherein said gaseous catalyst has a net enthalpy of reaction of about 27.2 eV.

291. A cell according to claim **274**, wherein said cell comprises said source of said gaseous catalyst combined with at least one of a hydrocarbon or water disposed such that said gaseous catalyst and said gaseous hydrogen atoms are capable being formed during combustion.

292. A cell according to claim **274**, further comprising a means for converting said source of catalyst to said gaseous catalyst.

293. A cell according to claim **292**, wherein said means for converting said source of catalyst to said gaseous catalyst comprises at least one of heat, electron-beam energy, photon energy, acoustic energy, electric field, or magnetic field.

294. A cell according to claim **274**, further comprising a filament coated with said source of gaseous catalyst.

295. A cell according to claim **274**, wherein said source of gaseous hydrogen atoms is selected from the group consisting of hydrogen gas, water, hydrides, metal-hydrogen solutions, and hydrocarbons.

296. A cell according to claim **274**, wherein said source of hydrogen atoms comprises a hot filament and a hydrogen containing gas stream.

297. A cell according to claim **274**, wherein said source of hydrogen atoms comprises a hot grid and a hydrogen containing gas stream.

298. A cell according to claim **274**, wherein said source of hydrogen atoms comprises a heated tungsten capillary and a hydrogen containing gas stream.

299. A cell according to claim **274**, wherein said source of hydrogen atoms comprises a hydride maintained under nonequilibrium conditions.

300. A cell according to claim **274**, wherein said source of hydrogen atoms comprises an inductively coupled plasma flow tube and a hydrogen gas containing stream.

301. A cell according to claim **274**, wherein said source of hydrogen atoms comprises a hydrogen containing gas stream and a second catalyst for disassociating said hydrogen containing gas stream into free hydrogen atoms.

302. A cell according to claim **274**, wherein said source of hydrogen atoms comprises an internal combustion engine.

303. A cell according to claim **301**, wherein said second catalyst comprises at least one element selected from the group consisting of transition elements, inner transition elements, precious metals, refractory metals, lanthanides, actinides, and activated charcoal.

304. A cell according to claim **301**, wherein said second catalyst comprises at least one selected from the group consisting of an element, compound, alloy or mixture of transition elements, inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal, and intercalated Cs carbon.

305. A cell according to claim **301**, wherein said second catalyst is treated with an aqueous solution of K_2CO_3 and H_2O_2.

306. A cell according to claim **301**, further comprising a heater to heat said second catalyst.

307. A cell according to claim **301**, further comprising a filament or grid constructed and arranged to dissociate hydrogen and to heat said second catalyst.

308. A cell according to claim **301**, further comprising means for controlling the power output of said cell.

309. A cell according to claim **308**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of said second catalyst.

310. A cell according to claim **309**, wherein said means for controlling the temperature of said second catalyst comprises a filament or grid.

311. A cell according to claim **301**, further comprising a temperature controlling structure capable of maintaining a selected atomic hydrogen partial pressure by controlling the temperature of said second catalyst.

312. A cell according to claim **311**, wherein said temperature controlling structure is at least one selected from the group consisting of an internal heater, an external heater, the catalysis of hydrogen, and a heat exchanger which removes energy from the cell.

313. A cell according to claim **274**, wherein said source of hydrogen atoms comprises a means for pyrolysis of hydrocarbons or water.

314. A cell according to claim **274**, further comprising means to reform hydrocarbons to at least one of gaseous molecular and gaseous atomic hydrogen.

315. A cell according to claim **274**, further comprising a source of UV light for disassociating hydrogen containing molecules to form said gaseous hydrogen atoms.

316. A cell according to claim **274**, further comprising a flow control means for controlling the flow of said source of gaseous hydrogen atoms or said gaseous hydrogen atoms from said chamber to said reaction vessel.

317. A cell according to claim **316**, wherein said flow control means comprises a valve.

318. A cell according to claim **274**, further comprising a flow control means for controlling the flow of hydrogen from said reaction vessel.

319. A cell according to claim **318**, wherein said flow control means comprises a valve.

320. A cell according to claim **274**, further comprising a vacuum pump constructed and arranged for controlling the flow of hydrogen from said reaction vessel.

321. A cell according to claim **274**, further comprising a flow control means for controlling the flow of said gaseous catalyst or a source of gaseous catalyst from said catalyst reservoir to said reaction vessel.

322. A cell according to claim **321**, wherein said flow control means comprises a valve.

323. A cell according claim **274**, further comprising means for controlling the flow of catalyst from said reaction vessel.

324. A cell according to claim **274**, further comprising a valve constructed and arranged for controlling the flow of said catalyst from said reaction vessel.

325. A cell according to claim **274**, further comprising a vacuum pump constructed and arranged for controlling the flow of said gaseous catalyst or source of gaseous catalyst from said reaction vessel.

326. A cell according to claim **274**, further comprising a nonreactive gas.

327. A cell according to claim **274**, further comprising a means for controlling the amount of a nonreactive gas in said vessel.

328. A cell according to claim **274**, further comprising flow control means for controlling the flow of a nonreactive gas into said reaction vessel.

329. A cell according to claim **328**, wherein said means for controlling the amount of nonreactive gas in said vessel comprises a valve constructed and arranged to regulate the release of said nonreactive gas from said reaction vessel.

330. A cell according to claim **274**, further comprising a valve constructed and arranged for controlling the flow of a nonreactive gas from said reaction vessel.

331. A cell according to claim **274**, further comprising a vacuum pump constructed and arranged for controlling the flow of a nonreactive gas from said reaction vessel.

332. A cell according to claim **274**, further comprising a pump in communication with said reaction vessel.

333. A cell according to claim **274**, further comprising structure for controlling the vapor pressure of said catalyst.

334. A cell according to claim **333**, wherein said structure for controlling the vapor pressure of said catalyst comprises a heater constructed and arranged to control the temperature of said catalyst reservoir or said boat.

335. A cell according to claim **333**, wherein said structure for controlling the vapor pressure of said catalyst comprises a heater constructed and arranged to control the temperature of said reaction chamber.

336. A cell according to claim **274**, further comprising structure for maintaining a selected vapor pressure of said gaseous catalyst.

337. A cell according to claim **336**, wherein said structure for maintaining a selected vapor pressure of said gaseous catalyst comprises a valve constructed and arranged for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir and a valve constructed and arranged for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said reaction vessel.

338. A cell according to claim **336**, wherein said structure for maintaining a selected vapor pressure of said source of gaseous catalyst or said gaseous catalyst comprises a valve constructed and arranged for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said reaction vessel.

339. A cell according to claim **274**, further comprising a valve for releasing hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1 or a compound containing said hydrogen atoms.

340. A cell according to claim **274**, further comprising means for adsorbing energy released from said hydrogen atom.

341. A cell according to claim **274**, wherein said vessel comprises an internal combustion chamber.

342. A cell according to claim **341**, wherein said internal combustion chamber is an engine cylinder.

343. A cell according to claim **274**, further comprising means for controlling the power output of said cell.

344. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the amount of said gaseous catalyst.

345. A cell according to claim **344**, wherein said means for controlling the amount of gaseous catalyst comprises means for controlling the temperature of said vessel and said gaseous catalyst is selected to have a vapor pressure dependent upon the temperature of said reaction vessel.

346. A cell according to claim **344**, wherein said means for controlling the amount of gaseous catalyst comprises means for controlling the temperature of said catalyst reservoir and said gaseous catalyst is selected to have a vapor pressure dependent upon the temperature of said catalyst reservoir.

347. A cell according to claim **344**, wherein said means for controlling the amount of gaseous catalyst comprises means for controlling the temperature of said boat and said gaseous catalyst is selected to have a vapor pressure dependent upon the temperature of said boat.

348. A cell according to claim **344**, wherein said means for controlling the amount of gaseous catalyst comprises means for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir into said reaction vessel.

349. A cell according to claim **344**, wherein said means for controlling the amount of gaseous catalyst comprises means for controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir from said reaction vessel.

350. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the amount of said gaseous hydrogen atoms or said source of gaseous hydrogen atoms in said vessel.

351. A cell according to claim **350**, wherein said means for controlling the amount of said gaseous hydrogen atoms or said source of gaseous hydrogen atoms comprises means for controlling the flow of gaseous hydrogen atoms or source of said hydrogen atoms into said vessel.

352. A cell according to claim **350**, wherein said means for controlling the amount of said gaseous hydrogen atoms or said source of gaseous hydrogen atoms comprises means for controlling the flow of gaseous hydrogen atoms or source of said hydrogen atoms from said vessel.

353. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises controlling the amount of said nonreactive gas present in said reaction vessel.

354. A cell according to claim **353**, wherein said means for controlling the amount of nonreactive gas comprises means for controlling the flow of said nonreactive gas into said reaction vessel.

355. A cell according to claim **354**, wherein said means for controlling the amount of nonreactive gas comprises means for controlling the flow of said nonreactive gas from said reaction vessel.

356. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of said source of catalyst.

357. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the flow of a hydrogen containing gas over at least one of a hot filament, a tungsten capillary heated by electron bombardment, or an inductively coupled plasma flow.

358. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the power dissipated in an inductively coupled plasma flow tube.

359. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of a hot filament or tungsten capillary heated by electron bombardment over which a hydrogen containing gas flows.

360. A cell according to claim **343**, wherein said means for controlling the power output of said cell comprises means for controlling the temperature of a hydride maintained under nonequilibrium conditions.

361. A cell according to claim **274**, further comprising means for measuring the temperature of said catalyst reservoir or said boat.

362. A cell according to claim **274**, further comprising a means for measuring the temperature of said source of said gaseous catalyst contained in said catalyst reservoir or said boat.

363. A cell according to claim **274**, further comprising means for measuring the temperature of said reaction vessel.

364. A cell according to claim **274**, further comprising means for measuring the temperature of said source of said gaseous hydrogen atoms.

365. A cell according to claim **301**, further comprising means for measuring the temperature said second catalyst.

366. A cell according to claim **274**, further comprising means to measure the cell temperature.

367. A cell according to claim **274**, further comprising temperature controlling structure constructed and arranged to maintain a temperature in said reaction vessel greater than a temperature in said catalyst reservoir.

368. A cell according to claim **274**, further comprising temperature controlling structure constructed and arranged to maintain a temperature in said reaction vessel greater than a temperature in said boat.

369. A cell according to claim **274**, further comprising temperature controlling structure for maintaining a selected temperature of said reaction vessel.

370. A cell according to claim **274**, further comprising a nebulizer or atomizer.

371. A cell according to claim **274**, further comprising means to measure the pressure in said reaction vessel.

372. A cell according to claim **274**, further comprising means to measure the hydrogen pressure in said reaction vessel.

373. A cell according to claim **274**, further comprising means to measure the gaseous catalyst pressure in said reaction vessel.

374. A cell according to claim **274**, wherein said vessel is capable of containing a pressure within the range of 10^{-3} atmospheres to 100 atmospheres.

375. A method for extracting energy from hydrogen atoms comprising the steps of:

volatizing a source of gaseous catalyst to form a gaseous catalyst having a net enthalpy of reaction of about 27*(p/2) eV, where p is an integer greater than 1;

providing gaseous hydrogen atoms; and

reacting said gaseous catalyst with said gaseous hydrogen atoms, thereby releasing energy from said gaseous hydrogen atoms and producing hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and a denominator is an integer greater than 1.

376. A method according to claim **375**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to hydrogen reduction.

377. A method according to claim **375**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to hydrogen reduction and which is adapted to sublime, boil or become volatile when heated.

378. A method according to claim **375**, wherein said source of gaseous catalyst comprises an ionic compound which is adapted to sublime, boil or become volatile when heated.

379. A method according to claim **375**, wherein said source of gaseous catalyst comprises an ionic compound which is resistant to thermal degradation.

380. A method according to claim **375**, wherein said source of gaseous catalyst comprises a salt of rubidium or potassium.

381. A method according to claim **375**, wherein said source of gaseous catalyst comprises a salt that can form a vapor comprising ions when heated.

382. A method according to claim **375**, wherein said source of gaseous catalyst comprises a salt of rubidium selected from the group consisting of RbF, RbCl, RbBr, RbI, Rb_2S_2, RbOH, Rb_2SO_4, Rb_2CO_3, and Rb_3PO_4.

383. A method according to claim **375**, wherein said source of gaseous catalyst comprises a salt of potassium selected from the group consisting of KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4, K_2CO_3, K_3PO_4, and K_2GeF_4.

384. A method according to claim **375**, wherein said source of gaseous catalyst comprises at least one metal selected from the group consisting of Mo, Ti, and Rb.

385. A method according to claim **375**, wherein said source of gaseous catalyst comprises at least one salt selected from the group consisting of MoI_2, $TiCl_2$, $TiCl_4$, $SnCl_4$, $SiCl_4$, $PrBr_3$, $CaBr_2$, $SrCl_2$, CrI_2, TbI_3, $SbCl_3$, CrF_3, $CoCl_2$, $BiCl_3$, $NiCl_2$, PdF_2, InCl, $LaCl_3$, $DyCl_3$, LaI_3, HoI_3, KNO_3, VF_3, PbF_2, VOCl, PbI_2, $LuCl_3$, $PbCl_2$, AsI_3, HoI_3, $MoCl_5$, $SnCl_4$, SbI_3, CdI_2, AgF_2, AgF, LaI_3, ErI_3, VCl_4, BCl_3, $FeCl_3$, $TiCl_3$, CoI_2, CoF_2, TlI, TlF, $BiBr_3$, $ZnBr_2$, AsI_3, DyI_3, $HoCl_3$, $MgCl_2$, $CrCl_3$, $PrCl_3$, $SrCl_2$, $FeCl_2$, $NiCl_2$, CuCl, $SrCl_2$, $MoCl_2$, YCl_3, $ZrCl_4$, CdI_2, BaI_2, HoI_3, PbI_2, PdF_2, LiF, $EuCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $BiCl_4$, $AlCl_3$, $CaBr_2$, $SmBr_3$, VaF_3, $LaCl_3$, GdI_3, CrI_2, MnI_2, $YbBr_3$, $FeBr_2$, $NiCl_2$, AgCl, $ZnCl_2$, $YbCl_2$, SeF_4, $SnCl_4$, SnF_4, SbI_3, BiI_2, EuF_3, and $PbCl_2$.

386. A method according to claim **375**, wherein said gaseous catalyst comprises at least one ion selected from the group consisting of Mo^{2+}, Ti^{2+}, and Rb^{+}.

387. A method according to claim **375**, wherein said gaseous catalyst comprises at least one pair of ions selected from the group consisting of: (Sn^{4+}, Si^{4+}), (Pr^{3+}, Ca^{2+}), (Sr^{2+}, Cr^{2+}), (Cr^{3+}, Tb^{3+}), (Sb^{3+},Co^{2+}), (Bi^{3+}, Ni^{2+}), (Pd^{2+}, In^{+}), (La^{3+}, Dy^{3+}), (La^{3+}, Ho^{3+}), (K^{+}, K^{+}), (V^{3+}, Pd^{2+}), (Lu^{3+}, Zn^{2+}), (As^{3+}, Ho^{3+}), (Mo^{5+}, Sn^{4+}), (Sb^{3+}, Cd^{2+}, (Ag^{2+},Ag^{+}), (La^{3+}, Er^{3+}), (V^{4+}, B^{3+}), (Fe^{3+}, Ti^{3+}), (Co^{2+}, Ti^{+}), (Bi^{3+}, Zn^{2+}), (As^{3+}, Dy^{3+}), (Ho^{3+}, Mg^{2+}), (K^{+}, Rb^{+}), (Cr^{3+}, Pr^{3+}), (Sr^{2+}, Fe^{2+}), (Ni^{2+}, Cu^{+}), (Sr^{2+}, Mo^{2+}), (Y^{3+}, Zr^{4+}), (Cd^{2+}, Ba^{2+}), (Ho^{3+}, Pb^{2+}), (Pb^{2+}, Li^{+}), (Eu^{3+}, Mg^{2+}), (Er^{3+}, Mg^{2+}), (Bi^{4+},Al^{3+}), (Ca^{2+}, Sm^{3+}), (V^{3+}, La^{3+}), (Gd^{3+}, Cr^{2+}), (Mn^{2+}, Ti^{+}), (Yb^{3+}, Fe^{2+}), (Ni^{2+}, Ag^{+}), (Zn^{2+}, Yb^{2+}), (Se^{4+}, Sn^{4+}), (Sb^{3+}, Bi^{2+}), and (Eu^{3+}, Pb^{2+}).

388. A method according to claim **375**, wherein said source of gaseous catalyst comprises a salt of one or more cations and at least one anion selected from the group consisting of halides, sulfates, phosphates, carbonates, hydroxide and sulfides.

389. A method according to claim **375**, wherein said gaseous catalyst comprises hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1.

390. A method according to claim **375**, wherein said catalyst is selected to have a resonant adsorption with the energy released from said gaseous hydrogen atoms undergoing a transition to a lower energy state.

391. A method according to claim **375**, wherein said gaseous catalyst comprises potassium and has a net enthalpy of reaction of 27.28 eV.

392. A method according to claim **375**, wherein said gaseous catalyst has a net enthalpy of reaction of about 27.2 eV.

393. A method according to claim **375**, further comprising the step of combining a source of gaseous catalyst with a source of gaseous hydrogen atoms comprising at least one of a hydrocarbon or water, and providing combustion which volatizes said source of gaseous catalyst to form said gaseous catalyst and provide said gaseous hydrogen atoms.

394. A method according to claim **375**, further comprising the step of forming said source of gaseous catalyst or said gaseous catalyst in situ.

395. A method according to claim **344**, wherein said step of forming said source of gaseous catalyst or said gaseous catalyst in situ comprises the ionization of a reactant.

396. A method according to claim **345**, wherein said step of ionization comprises thermal ionization of said reactant.

397. A method according to claim **395**, wherein said step of ionization comprises chemical ionization of said reactant.

398. A method according to claim **397**, wherein said step of chemical ionization comprises oxidation or reduction of said reactant.

399. A method according to claim **375**, wherein said step of volatizing said source of catalyst to form said gaseous catalyst utilizes energy from at least one of heat, electron-beam energy, photon energy, acoustic energy, electric field, or magnetic field.

400. A method according to claim **375**, wherein said step of volatizing said source of catalyst comprises the step of heating a filament coated with said source of said gaseous catalyst.

401. A method according to claim **375**, wherein said step of volatizing said source of gaseous catalyst to form said gaseous catalyst comprises the steps of volatizing said material to form gaseous atoms and ionizing said gaseous atoms to form ions.

402. A method according to claim **375**, further comprising adding a source of catalyst to said reaction vessel and heating said source of catalyst to form said gaseous catalyst.

403. A method according to claim **375**, wherein said source of catalyst is provided in a catalyst reservoir comprising a container separate from said reaction vessel and said container communicates with said reaction vessel.

404. A method according to claim **375**, wherein said source of catalyst is provided in a boat contained within said reaction vessel.

405. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of disassociating a hydrogen containing compound into hydrogen atoms.

406. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas over a hot filament.

407. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas over a hot grid.

408. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas through a tungsten capillary heated by electron bombardment.

409. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of maintaining a hydride under nonequilibrium conditions.

410. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of passing a hydrogen containing gas through an inductively coupled plasma flow tube.

411. A method according to claim **375**, wherein said step of providing hydrogen atoms comprises the steps of contacting a hydrogen containing gas with a second catalyst for disassociating said hydrogen containing gas into free hydrogen atoms.

412. A method according to claim **411**, wherein said second catalyst comprises at least one element selected from the group consisting of transition elements, inner transition elements, precious metals, refractory metals, lanthanides, actinides and activated charcoal.

413. A method according to claim **411**, wherein said second catalyst is selected from the group consisting of an element, compound, alloy or mixture of transition elements, inner transition elements, iron, platinum, palladium, zirconium, vanadium, nickel, titanium, Sc, Cr, Mn, Co, Cu, Zn, Y, Nb, Mo, Tc, Ru, Rh, Ag, Cd, La, Hf, Ta, W, Re, Os, Ir, Au, Hg, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Vb, Lu, Th, Pa, U, activated charcoal, and intercalated Cs carbon.

414. A method according to claim **411**, further comprising the step of utilizing a hot filament or hot grid to disassociate a hydrogen containing gas into gaseous hydrogen atoms and to heat said second catalyst.

415. A method according to claim **411**, further comprising the step of controlling the power output of said cell.

416. A method according to claim **415**, wherein said step of controlling the power output of said cell comprises controlling the temperature of said second catalyst.

417. A method according to claim **416**, wherein said step of controlling the temperature of said second catalyst comprises utilizing a heated filament or grid.

418. A method according to claim **375**, wherein said source of gaseous hydrogen atoms is selected from the group consisting of hydrogen gas, water, hydrides, metal-hydrogen solutions, and hydrocarbons.

419. A method according to claim **375**, wherein said step of providing gaseous hydrogen atoms comprises pyrolyzing hydrocarbons or water.

420. A method according to claim **375**, further comprising the step of reforming hydrocarbons to at least one of gaseous molecular and gaseous atomic hydrogen.

421. A method according to claim **375**, further comprising the step of disassociating hydrogen containing molecules using UV light to form said gaseous hydrogen atoms.

422. A method according to claim **375**, further comprising the step of controlling the amount of gaseous hydrogen provided in said reaction vessel.

423. A method according to claim **375**, further comprising the step of controlling the flow of a source of gaseous hydrogen atoms or said gaseous hydrogen atoms from a chamber to said reaction vessel.

424. A method according to claim **375**, further comprising the step of utilizing a valve for controlling the flow of gaseous hydrogen or source of gaseous hydrogen from said reaction vessel.

425. A method according to claim **375**, further comprising the step of controlling the flow of gaseous hydrogen or source of gaseous hydrogen from said reaction vessel.

426. A method according to claim **375**, further comprising the step of utilizing a vacuum pump for controlling the flow of gaseous hydrogen or source of gaseous hydrogen from said reaction vessel.

427. A method according to claim **375**, further comprising the step of utilizing a valve for controlling the flow of gaseous hydrogen or source of gaseous hydrogen from a chamber into said reaction vessel.

428. A method according to claim **375**, further comprising controlling the partial pressure of said gaseous hydrogen atoms.

429. A method according to claim **375**, wherein a partial pressure of said gaseous hydrogen atoms or source of gaseous hydrogen atoms in said reaction vessel is maintained within the range of 10^{-3} atmospheres to 100 atmospheres.

430. A method according to claim **375**, further comprising controlling the amount of gaseous catalyst or source of gaseous catalyst introduced into said reaction vessel.

431. A method according to claim **375**, further comprising controlling the flow of gaseous catalyst or source of gaseous catalyst from a catalyst reservoir containing gaseous catalyst or a source of gaseous catalyst to said reaction vessel.

432. A method according to claim **375**, further comprising controlling the flow of gaseous catalyst or source of gaseous catalyst from a boat containing gaseous catalyst or a source of gaseous catalyst.

433. A method according to claim **375**, further comprising the step of controlling the flow of said gaseous catalyst or said source of gaseous catalyst from said reaction vessel.

434. A method according to claim **375**, further comprising the step of controlling the vapor pressure of said gaseous catalyst or source of gaseous catalyst in said reaction vessel.

435. A method according to claim **375**, wherein a vapor pressure of said gaseous catalyst or said source of gaseous catalyst is maintained at about 50 to 210 millitorr.

436. A method according to claim **375**, further comprising using a vacuum pump to control the flow of said catalyst or said source of gaseous catalyst from said reaction vessel.

437. A method according to claim **375**, further comprising using a valve to control the flow of said source of gaseous catalyst or said catalyst from a catalyst reservoir into said reaction vessel.

438. A method according to claim **375**, further comprising using a valve to control the flow of said source of gaseous catalyst or said catalyst from said reaction vessel.

439. A method according to claim **375**, further comprising the step of supplying a nonreactive gas to said reaction vessel.

440. A method according to claim **375**, further comprising the step of controlling the vapor pressure of said nonreactive gas in said reaction vessel.

441. A method according to claim **440**, further comprising the step of controlling the flow of said nonreactive gas supplied to said reaction vessel.

442. A method according to claim **440**, further comprising the step of controlling the amount of said nonreactive gas released from said reaction vessel.

443. A method according to claim **440**, further comprising utilizing a vacuum pump for controlling the flow of said nonreactive gas from said reaction vessel.

444. A method according to claim **440**, further comprising the step of utilizing a valve for controlling the flow of said nonreactive gas from said reaction vessel.

445. A method according to claim **440**, further comprising the step of utilizing a valve for controlling the flow of said nonreactive gas into said reaction vessel.

446. A method according to claim **375**, further comprising the step of controlling the vapor pressure of said gaseous catalyst in said reaction vessel.

447. A method according to claim **446**, wherein said step of controlling the vapor pressure of said gaseous catalyst comprises controlling the temperature in a catalyst reservoir containing a source of gaseous catalyst or said gaseous catalyst and being in communication with said reaction vessel, and controlling the flow of gaseous catalyst from said catalyst reservoir.

448. A method according to claim **446**, wherein said step of controlling the vapor pressure of said gaseous catalyst comprises controlling the temperature in a boat containing a source of gaseous catalyst or said gaseous catalyst and being contained in said reaction vessel, and controlling the flow of gaseous catalyst from said boat.

449. A method according to claim **375**, further comprising the step of controlling the temperature in a catalyst reservoir containing a source of gaseous catalyst or said gaseous catalyst and being in communication with said reaction vessel.

450. A method according to claim **375**, further comprising the step of controlling the temperature in a boat containing a source of gaseous catalyst or said gaseous catalyst and being contained in said reaction vessel.

451. A method according to claim **375**, wherein the reaction to provide a net enthalpy of about 27 (p/2) eV, where p is a positive integer greater than 1, comprises an electrochemical, chemical, photochemical, thermal, free radical, sonic, nuclear, inelastic photon, or particle scattering reaction, or mixtures thereof.

452. A method according to claim **375**, wherein a pressure in said reaction vessel is maintained within the range of 10^{-3} atmospheres to 100 atmospheres.

453. A method according to claim **375**, wherein said reaction occurring at a pressure less than atmospheric pressure.

454. A method according to claim **375**, further comprising the step of releasing hydrogen atoms from said reaction vessel having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1 or a compound containing said hydrogen atoms.

455. A method according to claim **375**, further comprising the step of adsorbing said released energy.

456. A method according to claim **375**, further comprising the step of converting energy released from said hydrogen atom into electrical energy.

457. A method according to claim **375**, wherein said reaction step is conducted in an internal combustion chamber.

458. A method according to claim **457**, wherein said internal combustion chamber is an engine cylinder.

459. A method according to claim **375**, further comprising the step of controlling the power output of said cell.

460. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the amount of said gaseous catalyst present in said reaction vessel.

461. A method according to claim **460**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the temperature of said reaction vessel and selecting said gaseous catalyst to have a vapor pressure dependent upon the temperature of said reaction vessel.

462. A method according to claim **460**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the temperature of a catalyst reservoir containing a source of gaseous catalyst or said gaseous and being in communication with said reaction vessel, and selecting said gaseous catalyst to have a vapor pressure dependent upon the temperature of said catalyst reservoir.

463. A method according to claim **460**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the flow of said source of gaseous catalyst or gaseous catalyst from said catalyst reservoir into said reaction vessel.

464. A method according to claim **460**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the flow of said source of gaseous catalyst or gaseous catalyst from said reaction vessel.

465. A method according to claim **460**, wherein said step of controlling the amount of gaseous catalyst comprises controlling the temperature of a boat containing a source of gaseous catalyst or said gaseous and being contained in said reaction vessel, and selecting said gaseous catalyst to have a vapor pressure dependent upon the temperature of said boat.

466. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the amount of said gaseous hydrogen atoms or source of gaseous hydrogen atoms present in said reaction vessel.

467. A method according to claim **466**, wherein said step of controlling the amount of said gaseous hydrogen atoms or source of gaseous hydrogen atoms comprises controlling the flow of gaseous hydrogen atoms or source of gaseous hydrogen atoms into said reaction vessel.

468. A method according to claim **466**, wherein said step of controlling the amount of said source of gaseous hydrogen atoms or gaseous hydrogen atoms comprises controlling the flow of said source of gaseous hydrogen atoms or gaseous hydrogen atoms from said reaction vessel.

469. A method according to claim **466**, wherein said step of controlling the amount of said source of gaseous hydrogen atoms or gaseous hydrogen atoms comprises controlling the temperature of a second catalyst for dissociating a hydrogen containing compound into gaseous hydrogen atoms.

470. A method according to claim **469**, wherein said step of controlling the temperature of a second catalyst for dissociating a hydrogen containing compound into gaseous hydrogen atoms comprises controlling the power dissipated in a second catalyst heater.

471. A method according to claim **459** wherein said step of controlling the power output of said cell comprises controlling the amount of nonreactive gas in said reaction vessel.

472. A method according to claim **471**, wherein said step of controlling the amount of nonreactive gas in said reaction vessel comprises controlling the flow of nonreactive gas into said reaction vessel.

473. A method according to claim **472**, wherein said step of controlling the amount of nonreactive gas in said reaction vessel comprises controlling the flow of nonreactive gas from said reaction vessel.

474. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the temperature of a source of gaseous catalyst.

475. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the flow of a hydrogen containing gas over at least one of a hot filament, a tungsten capillary heated by electron bombardment, or an inductively coupled plasma flow.

476. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the power dissipated in an inductively coupled plasma flow tube, hot filament or grid, or tungsten capillary heated by electron bombardment.

477. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the temperature of a hot filament or tungsten capillary heated by electron bombardment over which a hydrogen containing gas flows.

478. A method according to claim **459**, wherein said step of controlling the power output of said cell comprises controlling the temperature of a hydride maintained under nonequilibrium conditions.

479. A method according to claim **375**, wherein a temperature in said reaction vessel is maintained at a higher temperature than in a catalyst reservoir in communication with said reaction vessel or a boat contained within said reaction vessel.

480. A method according to claim **375**, further comprising the step of measuring the temperature of a catalyst reservoir in communication with said reaction vessel or a boat contained in said reaction vessel.

481. A method according to claim **375**, further comprising the step of measuring the temperature of a source of said gaseous catalyst contained in a catalyst reservoir in communication with said reaction vessel or a boat contained within said reservoir.

482. A method according to claim **375**, further comprising the step of measuring the temperature of a chamber containing a source of said hydrogen atoms in communication with said reaction vessel.

483. A method according to claim **375**, further comprising the step of measuring the temperature of a source of said gaseous hydrogen atoms.

484. A method according to claim **411**, further comprising the step of measuring the temperature of said second catalyst.

485. A method according to claim **375**, further comprising the step of controlling the temperature of said reaction vessel.

486. A method according to claim **375**, further comprising utilizing a nebulizer or atomizer to form said gaseous catalyst.

487. A method according to claim **375**, further comprising the step of measuring the pressure in said reaction vessel.

488. A method according to claim **375**, further comprising the step of controlling the pressure in said reaction vessel.

489. A method according to claim **375**, further comprising the step of measuring the hydrogen pressure in said reaction vessel.

490. A method according to claim **375**, further comprising the step of measuring the gaseous catalyst pressure in said reaction vessel.

491. A method according to claim **375**, further comprising the step of converting energy released from said gaseous hydrogen atoms into electrical energy.

492. A method according to claim **375**, further comprising controlling the pressure of said gaseous catalyst by controlling the amount of said source of catalyst being added to said reaction vessel.

493. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen.

494. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen and releasing energy from said hydrogen atom, wherein said gaseous catalyst comprises hydrogen atoms having a binding energy of about $E_b=13.6/n^2$ eV, where n is a fraction whose numerator is 1 and denominator is an integer greater than 1.

495. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen and releasing energy from said hydrogen atom, wherein said source of gaseous catalyst comprises at least one salt selected from the group consisting of RbF, RbCl, RbBr, RbI, Rb_2S_2, RbOH, Rb_2SO_4, Rb_2CO_3, Rb_3PO_4, KF, KCl, KBr, KI, K_2S_2, KOH, K_2SO_4, K_2CO_3, K_3PO_4, and K_2GeF_4.

496. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen and releasing energy from said hydrogen atom, wherein said gaseous catalyst comprises at least one ion selected from the group consisting of Mo^{2+}, Ti^{2+}, and Rb^+.

497. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen and releasing energy from said hydrogen atom, wherein said source of gaseous catalyst comprises at least one metal selected from the group consisting of Mo, Ti, and Rb.

498. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen and releasing energy from said hydrogen atom, wherein said source of gaseous catalyst comprises at least one salt selected from the group consisting of MoI_2, $TiCl_2$, $TiCl_4$, $SnCl_4$, $SiCl_4$, $PrBr_3$, $CaBr_2$, $SrCl_2$, CrI_2, TbI_3, $SbCl_3$, CrF_3, $CoCl_2$, $BiCl_3$, $NiCl_2$, PdF_2, InCl, $LaCl_3$, $DyCl_3$, LaI_3, HoI_3, KNO_3, VF_3, PbF_2, VOCl, PbI_2, $LuCl_3$, $PbCl_2$, AsI_3, HoI_3, $MoCl_5$, $SnCl_4$, SbI_3, CdI_2, AgF_2, AgF, LaI_3, ErI_3, VCl_4, BCl_3, $FeCl_3$, $TiCl_3$, CoI_2, CoF_2, TlI, TlF, $BiBr_3$, $ZnBr_2$, AsI_3, DyI_3, $HoCl_3$, $MgCl_2$, $CrCl_3$, $PrCl_3$, $SrCl_2$, $FeCl_2$, $NiCl_2$, CuCl, $SrCl_2$, $MoCl_2$, YCl_3, $ZrCl_4$, CdI_2, BaI_2, HoI_3, PbI_2, PdF_2, LiF, $EuCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $ErCl_3$, $MgCl_2$, $BiCl_4$, $AlCl_3$, $CaBr_2$, $SmBr_3$, VaF_3, $LaCl_3$, GdI_3, CrI_2, MnI_2, $YbBr_3$, $FeBr_2$, $NiCl_2$, AgCl, $ZnCl_2$, $YbCl_2$, SeF_4, $SnCl_4$, SnF_4, SbI_3, BiI_2, EuF_3, and $PbCl_2$.

499. A cell comprising:

a reaction vessel capable of containing a vacuum or pressures greater than atmospheric;

a source of hydrogen atoms; and

a source of a gaseous catalyst or a gaseous catalyst capable of accepting energy from atomic hydrogen thereby catalyzing a transition of the electron of atomic hydrogen to a state lower than that of uncatalyzed hydrogen and releasing energy from said hydrogen atom, wherein said gaseous catalyst comprises at least one pair of ions selected from the group consisting of: (Sn^{4+}, Si^{4+}), (Pr^{3+}, Ca^{2+}), (Sr^{2+}, Cr^{2+}), (Cr^{3+}, Tb^{3+}), (Sb^{3+}, Co^{2+}), (Bi^{3+}, Ni^{2+}), (Pd^{2+}, In^+), (La^{3+}, Dy^{3+}), (La^{3+}, Ho^{3+}), (K^+, K^+), (V^{3+}, Pd^{2+}), (Lu^{3+}, Zn^{2+}), (As^{3+}, Ho^{3+}), (Mo^{5+}, Sn^{4+}), (Sb^{3+}, Cd^{2+}), (Ag^{2+},Ag^+), (La^{3+}, Er^{3+}), (V^{4+}, B^{3+}), (Fe^{3+}, Ti^{3+}), (Co^{2+}, Ti^+), (Bi^{3+}, Zn^{2+}), (As^{3+}, Dy^{3+}), (Ho^{3+}, Mg^{2+}), (K^+, Rb^+), (Cr^{3+}, Pr^{3+}), (Sr^{2+}, Fe^{2+}), (Ni^{2+}, Cu^+), (Sr^{2+}, Mo^{2+}), (Y^{3+}, Zr^{4+}), (Cd^{2+}, Ba^{2+}), (Ho^{3+}, Pb^{2+}), (Pb^{2+}, Li^+), (Eu^{3+}, Mg^{2+}), (Er^{3+}, Mg^{2+}), (Bi^{4+}, Al^{3+}), (Ca^{2+}, Sm^{3+}), (V^{3+}, La^{3+}), (Gd^{3+}, Cr^{2+}), (Mn^{2+}, Ti^+), (Yb^{3+}, Fe^{2+}), (Ni^{2+}, Ag^+), (Zn^{2+}, Yb^{2+}), (Se^{4+}, Sn^{4+}), (Sb^{3+}, Bi^{2+}), and (Eu^{3+}, Pb^{2+}).

CLASSIFICATIONS: PROGRAM MANAGER & SENIOR SCIENTIST
(TOP SECRET CLEARANCE)

EXPERIENCE:

Lockheed Martin Aeronautics Company, 1986 to 2000 (and present consultant), Mr. Bushman has participated in Advanced Aircraft Concepts as a member of the technical team. He has conducted European Theater Tactical Fighter performance analysis, coordinated customer interface and development performance concepts. He developed laser, electro-optical sensor, and power systems. He developed and taught analysis courses. Several million-dollar contracts were obtained directly from him. Bushman holds 26 US Patents and classified Patents.

Texas Instruments, 1979-1987, Mr. Bushman worked on the development of laser guided smart bombs, Tank Mounted Infrared FLIR systems, focal plane arrays and GPS Systems all of which are currently deployed as major components of Tactical Land Air and Sea systems.

From 1976 to 1979 Mr. Bushman was a Manager at Parsons International of Iran, Mexico and then Louisiana with the U.S. department of Energy's Strategic Oil Reserve Program. He managed a division of Trans Universal Finance Company in Southern California. Funding was obtained for high multimillion dollar projects.

At Hughes Aircraft (Now Ratheon), 1968-1976, Mr. Bushman was the Manager/Technical Liaison officer to the Infrared Sensor Division (SBRC Santa Barbara Research Center). He was involved in technical description and financial disbursement. Systems were deployed to aircraft and satellite systems.

At Electro-Optical Systems (Now Ratheon), 1966-1968 as Program manager, he developed and produced Night Vision Image Intensifier Systems for military night operations. These are similar to night vision goggles used by pilots. Mr. Bushman achieved sustained production of hundreds of units per month.

1963-1966, General Dynamics (Pomona), he coordinated the analysis, test and development producing the Redeye (Now Stinger Missile). The development and testing was achieved in concert with Sidewinder Missile Development team at China Lake Test Facility in California. Mr. Bushman coordinated the computer based operations analysis and system performance analysis for missile development and manufacture.

Magnetic Beam Amplifier

Here's more info about Bushman's Magnetic Beam Amplifier. It's interesting that it can provide a conductive channel in the air to produce 5-foot long sparks from high voltage. A long time ago I made and tested the unbalanced capacitor (It consists of parallel conducting plates, with a plurality of pins or points on one set of plates, facing the opposite plate, and separated by a dielectric, and air gap.). It didn't work, but I've just found that I connected it incorrectly, so I'll be testing it again.

http://web.archive.org/web/20040602192943/http://www.hometown.aol.com/dmboss1021/Page300.html

"An interesting effect he mentions is to have two such devices aimed at each other, and separated by up to five feet, with one having all south poles inward, and the other all north poles inward. And place a high voltage source adjacent to one beam source (such as a Van De Graff generator - set to cause sparks to jump 3/4" - meaning approx 7,500 volts in standard air) that there will be an arc extending along this beam for the entire five feet, to the other beam device!

I find this claim to very interesting, as the PE theory, indicates this energy is responsible for matter formation, and gravity, and that there is implied in the theory a method to generate electrical power directly from a "gravity beam".

This is due to the Tendency for nuclei and electrons to remain in their respective nodes and antinodes of this PE, and a preferential drift of these nodes/antinodes results in what we observe as the attraction of gravity. If you have some free electrons in a conductor or in a semi or quasi conductor - they would be influenced by this anti nodal drift.

If the mass of this material (either conductor or quasi conductor) is not free to move under the influence of this nodal/anitnodal drift (gravity), there would then be a tendency to produce an electric charge separation, as the free electrons would be induced to drift. This charge separation would result in an excess negative charge in the direction of the gravity - for example: the preferential drift near the earth is towards the planet, and thus one should expect that free electrons in the atmosphere (a quasi conductor and dielectric) would drift towards the planet under this influence.

The bulk mass of the atmosphere is pushed towards the planet, but reaches an equilibrium from the "pressure" of the air molecules against each other. The free electrons are not necessarily subject to this same equilibrium, and would continue to drift towards the planet. This results in the natural (and not fully explained by conventional science) electric field in the atmosphere!

This mechanism may explain the natural electric field of the atmosphere, as being due to gravity. And it follows that if one can create an isolated gravity beam of this nodal drift - that if you fix a conductor, or quasi conductor in this beam, that a charge separation will occur. You could then harness this energy directly as electrical current.

So if this magnetic beam amplifier is actually a concentrated PE beam, then perhaps this anomalous arcing effect is due to the gravitic nature of the "beam", in a similar manner as noted above. "

Jaro

December 09, 2012

Boyd Bushman Formerly of the SKUNK Works

Seriously do you really need to know a sixty year old secret? I think it is time for us to know the truth. We flew out first anti gravity craft in the fifties a decade after the Roswell crash. Yeah it was tethered to a power cable but we are way beyond that first working model today in 2012. Boyd Bushman has built the Apparatus and Method for amplifying a magnetic beam – US Patent Issued on July 27, 1999. The technology involves the careful spinning of the liquid metal Mercury. In this video Boyd Bushman demonstrates the spinning CELT I think he called it. Its about the three thirty minute mark. It is an incredible display of energy and when you couple that with mercury you are able to generate huge magnetic forces and propulsion. His experiments on the Hutchinson effect show that magnetism can cancel gravity. Basically he took two rocks one with a pair of super magnets bolted together inside the rock and the other without the magnets. The one with bolted super magnets produced a three foot radius magnetic field around the rock. that is the increases the repulsive force. The result of dropping these two items from some height within the gravitational pull of the earth was that the rock with the magnets arrived later. This is incredibly significant in the world pf physics and shows the link between magnetic and gravity. An incredibly important step in finding the unified field theories that Relativity have somewhat led us away from. Boyd Bushman was a major leading player in the work done at the SKUNK Works over the last few decades. This is another high ranking official trying to release the skepticism in Americans so we can open our borders and our minds to the Visitors. Boyd Bushman confirms that we have nuclear powered magnetic propulsion craft that can reach heights of 60,000 feet and operate with distance specifications in the thousands of miles. Once again there are no Aliens because America does not believe in them and the true Exo-Political party in charge is not yet ready to take a step forward. Sixty years of darkness is too long already. Most Americans are UFO skeptics, have not really researched what is going on and don't want to be laughed at. I must be crazy but I think this is the scientist who created the craft and is describing parts of the technological road map from finding the craft, to measuring the craft dynamics, duplicating the dynamics and prototyping working models. Less than 10K hits on youtube for a man who built the magnetic propulsion technology. Then again I am not a skeptic anymore.

FIG. 2

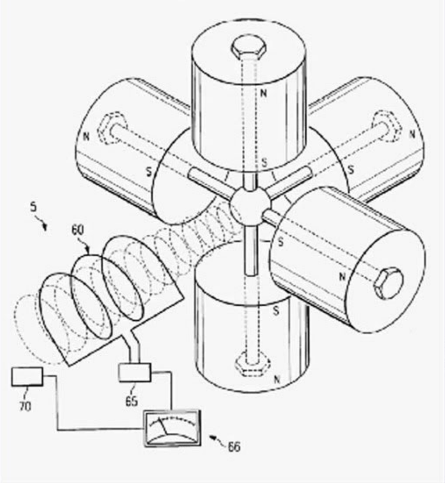

FIG. 3

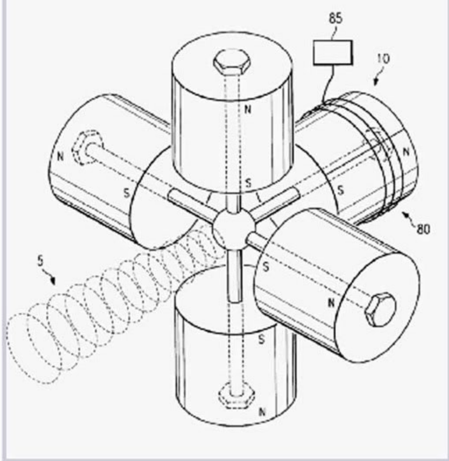
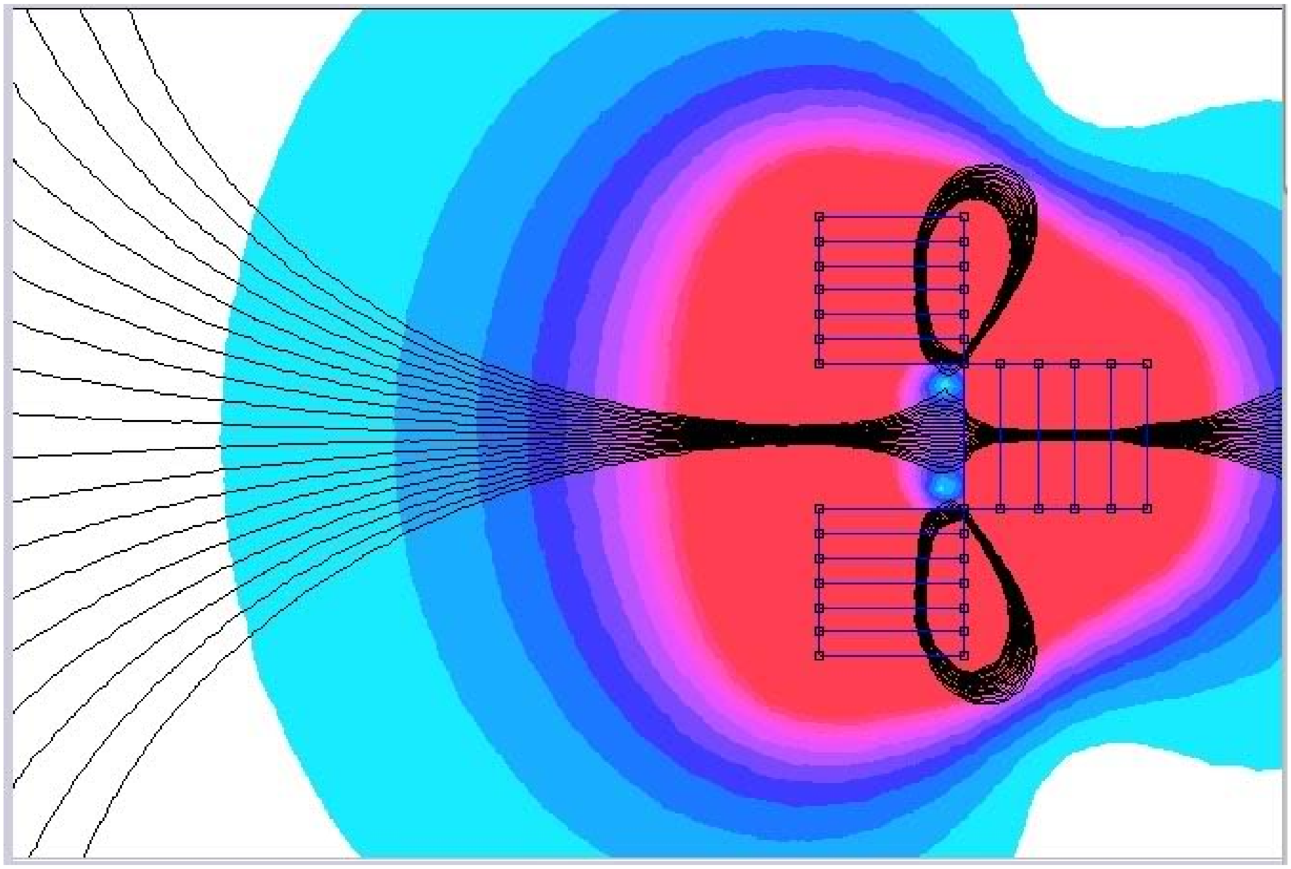


This is the Beamer Patent Drawing

According to the patent, this configuration creates a beam of some kind, represented by the series of dotted line circles extending out from the device. The author claims it is magnetic energy, but my own magnetic field analysis, and experiments show the magnetic field, while enhanced in this direction, does not appear to extend out to five feet as is claimed in the patent. (the magnetic flux does not appear to go this far at any appreciable strength, but a subtle energy effect does!)



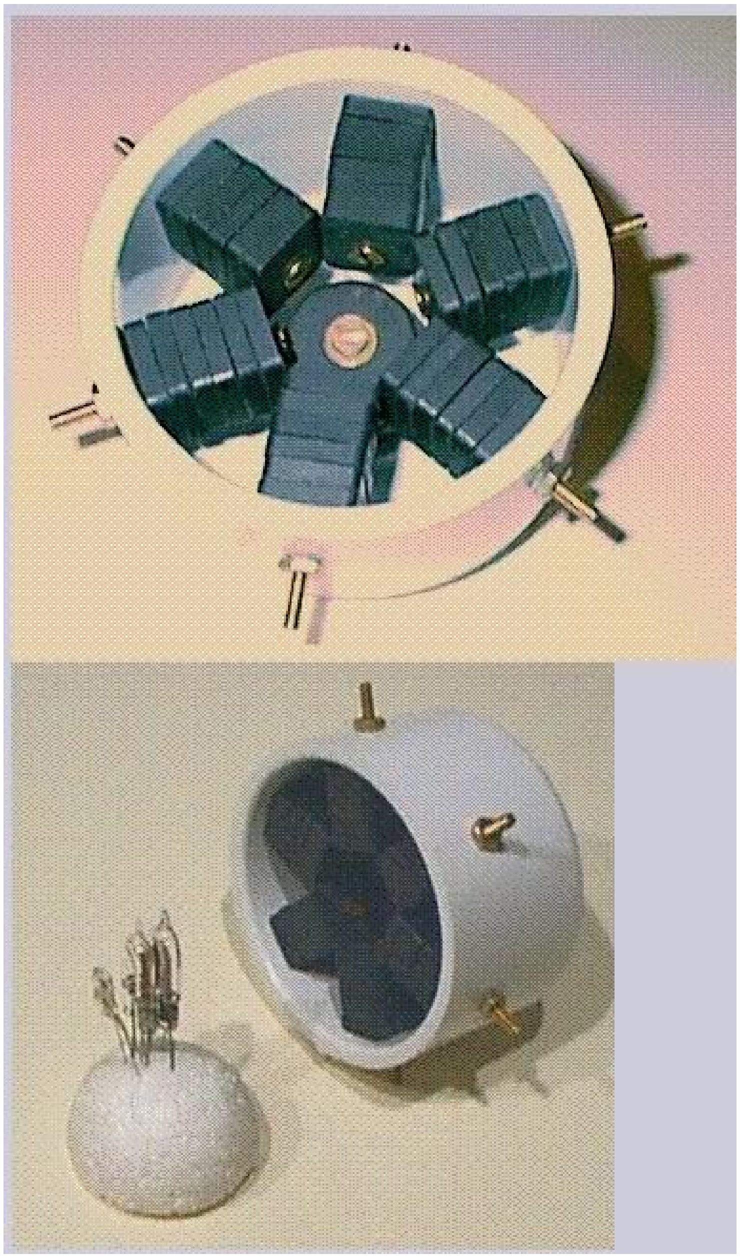
This is a plot of the magnetic field given off by a Beamer

The unusual properties of this beam, as described by the author, are very similar to the properties of a Primary Energy beam. And as the inert gases do exist as natural components of air, perhaps this beam he speaks of is a concentrated PE beam? (note in the next chapter a more powerful "Beamer" device is constructed, and it has a PE emanation all the time - and more so when you insert inert gas tubes into the "beam" area.)

He further claims that if you place a conductive coil (60) in the beam, and connected in series with a special unbalanced capacitor (65), and a voltmeter; that a voltage is produced which will vary if any object is in the beam, or any movement occurs in the beam. (yet to be tested)

Alternatively, if you place just the special capacitor in the beam (70),it will register a voltage if any movement occurs in the beam.

He further claims that if you place a coil over the unopposed magnet (80), and apply an ac current at various frequencies, you can modulate this beam, causing various effects at a distance.



This is an experimental Beamer

I hope this will be interesting and of some use perhaps

Neil

Replicating the Boyd Bushman Gravitational Experiment
by William Alek and Michael Ellegion

"Could gravity be related to its cousin magnetism?" Boyd Bushman's experiment is performed by others with similar results :

(SNNS) Opposing magnets inside the rock cause it to fall slower.

(NSNS) Attracting magnets inside the rock cause it to fall faster.

US5929732
Apparatus and method for amplifying a magnetic beam

Inventor(s): BUSHMAN BOYD B

An apparatus and method for creating a magnetic beam wherein a focusing magnet assembly (45) is comprised of a first opposing magnet pair (20) and a second opposing magnet pair (30) disposed in a focusing plane, each magnet of the respective opposing magnet pairs having a like pole directed towards the geometric center of the focusing magnet assembly (45) to form an alignment path, two like magnetic beams extending from the alignment path on each side of the focusing magnet assembly (45), each beam being generally perpendicular to the focusing plane. A like pole of an unopposed magnet (10) can be directed down the alignment path from one side of the focusing magnet assembly (45) to produce a single magnetic beam extending generally perpendicular from the focusing magnet assembly opposite unopposed magnet (10). **This beam is a magnetic monopole which emits pulses, levitates, degausses, stops electronics and separates materials.**

TECHNICAL FIELD OF THE INVENTION

The present invention relates generally to the field of magnetic devices, and more particularly to focusing a magnetic field to increase the efficiency of a magnet.

BACKGROUND OF THE INVENTION

Magnets have a variety of commercial uses. For instance, magnets perform a variety of physical tasks by attracting ferric materials, and magnets also perform a variety of electrical tasks, such as creating an electric current in a generator or alternator or enhancing the performance of electromagnetic devices such as inductors. However, the creation of a strong magnetic field to perform these functions generally entails the use of a large permanent magnet or a powerful electromagnet. Such magnets are often physically large and heavy, and tend to produce wide magnetic fields which can interfere with equipment near the magnet. Thus, commercial devices that include magnets must be designed around the physical size of the magnet needed to produce a desired magnetic field and around the width of the magnetic field produced.

SUMMARY OF THE INVENTION

Therefore, a need has arisen for an apparatus and method for manipulating and focusing the magnetic field of a magnet to reduce the size and strength required for a given magnet to perform a function.

In accordance with the present invention, an apparatus and method is provided that substantially eliminates or reduces disadvantages and problems associated with previously used unfocused magnets. The present invention uses opposing magnetic pairs to direct a magnetic field along an alignment axis.

More specifically, the present invention focuses a magnetic beam along an alignment axis by providing a focusing magnet assembly having at least three opposing magnets spaced apart in a focusing plane, the space between the opposing magnets forming an alignment path, and by further providing an unopposed magnet generally directed along the alignment axis towards the alignment path. Each opposing magnet has a like pole facing across the alignment path. The alignment axis corresponds to the alignment path formed by the spacing between the focusing assembly of magnets. In one alternative embodiment, the unopposed magnet can be placed in the focusing plane to form opposing magnet pairs which direct a magnetic beam from the alignment path along the alignment axis from each side of the focusing assembly.

In one alternative embodiment, a coil of conducting material is disposed in the magnetic beam near the exit of the beam from the focusing magnet assembly. An unbalanced capacitor and a voltmeter connected in series with the coil allow the detection of movement through the magnetic beam by measuring variations in the AC voltage of the coil. Alternatively, AC voltage can be measured from a pin array disposed in the beam as a substitute for the coil and unbalanced capacitor. In yet another embodiment, electric power, such as an alternating current, can be passed through coils arranged around one or more of the magnets of the assembly to allow the generation of a magnetic pulse.

The focused magnetic beam or beams produced by the present invention provides important technical advantages by focusing a magnetic field. The focused field may perform functions using less total magnetic force than is generally used by an unfocused magnet. This allows for the use of smaller permanent magnets, or alternatively, electromagnets that use lower amounts of electric power. Thus, a commercial device built with magnets according to the present invention **can be built smaller and with less of a need for power consumption** than devices using standard magnets. For instance, the present invention **can be used to more effectively separate ferric materials from non-ferric materials**, and can more effectively **induce propulsion or levitation** in systems that use magnetic fields, such as electric motors or levitating trains that use opposing magnetic fields. The present invention can also interact with electromagnetic devices such as computers by **stopping the operation of analog circuits from a distance, degaussing and otherwise interfering with digital circuits and memories, and emitting high powered electromagnetic pulses (EMP) at such circuits when induction coils are energized around the magnets with an alternating current. The present invention can also direct or transport electromagnetic charges through a distance.**

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete understanding of the present invention and advantages thereof may be acquired by referring to the following description taken in conjunction with the accompanying drawings in which like reference numbers indicate like features and wherein:

FIG. 1 depicts an assembly of five magnets to produce a magnetic beam;

FIG. 2 depicts a magnetic beam adapted to detect motion; and

FIG. 3 depicts an electronic coil disposed around an opposing magnet for producing a magnetic pulse beam.

FIG. 1

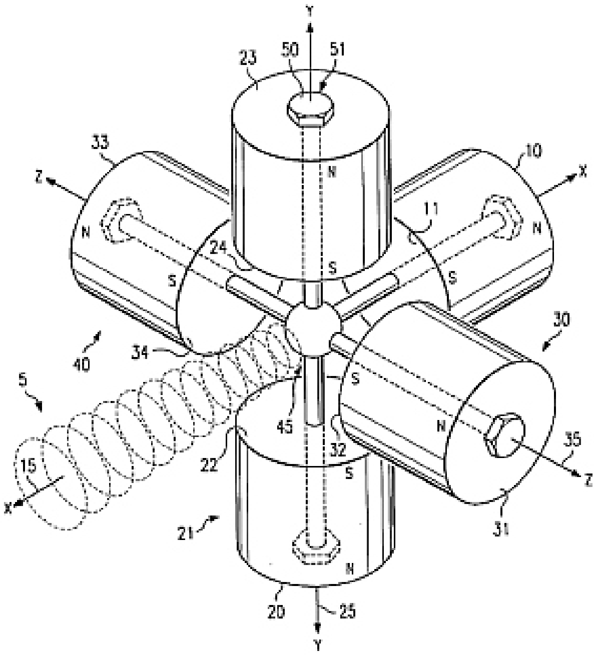

FIG. 2

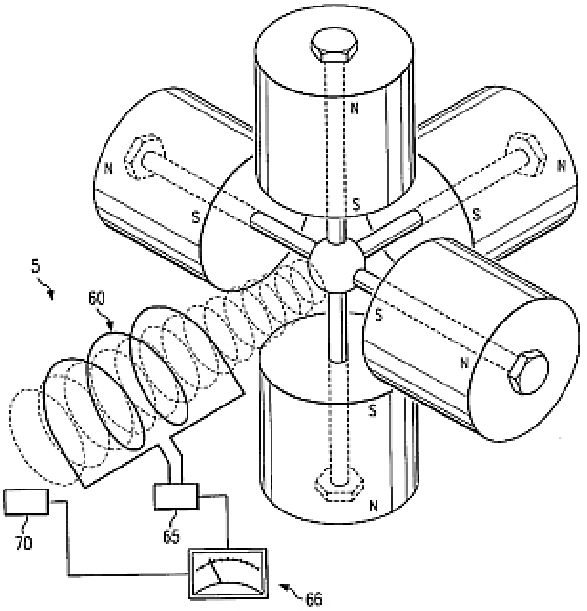

FIG. 3

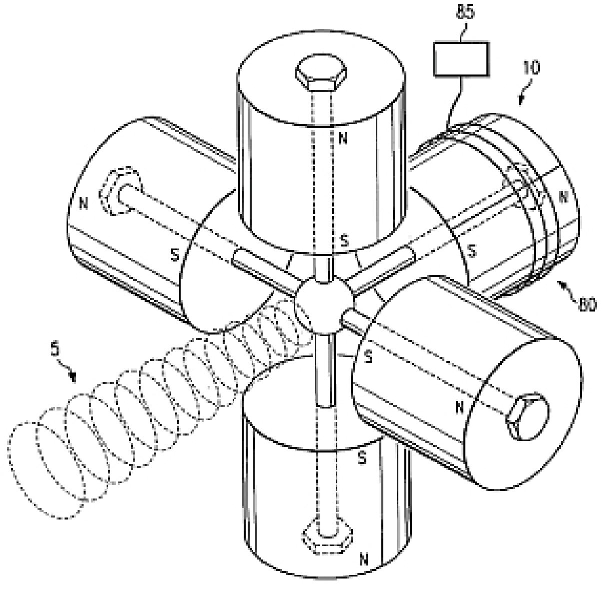

DETAILED DESCRIPTION OF THE INVENTION

Preferred embodiments of the present invention are illustrated in the figures, like numerals being used to refer to like and corresponding parts of the various drawings.

Referring now to FIG. 1, one embodiment of the present invention is depicted creating a south magnetic beam 5. A single unopposed magnet 10 is aligned along an alignment axis 15 so that the south pole 11 of magnet 10 points substantially in the direction of the intended magnetic beam. The alignment axis 15 in FIG. 1 is labeled as the "X" axis. A first opposing magnet pair 20 is disposed along a first or "Y" axis 25 substantially perpendicular to the alignment axis 15. Opposing magnet pair 20 is comprised of two magnets, 21 and 23, substantially aligned along the "Y" axis 25 so that the south pole 22 of magnet 21 and the south pole 24 of magnet 23 face each other. Magnets 21 and 23 are arranged to have a space between them which coincides with the path of alignment axis 15.

A second opposing magnet pair 30 is disposed along a second or "Z" axis 35, which is substantially perpendicular to the alignment axis 15 and also substantially perpendicular to the "Y" axis 25, the first and second magnet pairs forming a focusing magnet assembly 40. Second opposing magnet pair 30 is comprised of two opposing magnets, 31 and 33, each substantially aligned along the "Z" axis 35 so that the south pole 32 of magnet 31 faces the south pole 34 of magnet 33. Magnets 31 and 33 are arranged with a space between them, the space coinciding with the path of the alignment axis 15. The spaces of first and second opposing magnet pairs 20 and 30 coincide to form an alignment path 45 through which the alignment axis 15 is disposed. The first axis 25 and second axis 35 intercept within alignment path 45 at the approximate geometric center of the magnet assembly to form a focusing plane.

In the embodiment depicted by FIG. 1, each magnet has approximately the same magnetic force, and each magnet is a niosyum magnet constructed in the form of a cylinder with a hole 50 down its center. Nonferric bolts 51 are inserted through each hole and intersect at the geographic center of the magnetic pairs, where the Nonferric bolts can be coupled to hold the magnets in place. In alternative embodiments, any other convenient means of coupling the magnets in place can be used, and alternative means of producing a magnetic force, such as electromagnets, can be used. In another embodiment, unopposed magnet 10 can be removed so that a magnetic beam extends along the alignment axis 15 from each side of the focusing plane.

The embodiment of FIG. 1 depicts a like pole of each magnet directed towards the geographic center of the focusing magnet assembly 40. In FIG. 1, the south pole of each magnet is depicted as directed at the alignment path 45 and at the geographic center of the focusing magnet assembly 40. In other embodiments, the north pole of each magnet can be directed at the geographic center. In either case, the coupling of like poles in a plane and the introduction of a like pole perpendicular to the plane acts to focus the magnetic fields of each magnet into a beam extending perpendicular from the focusing plane along the alignment axis 15 of the single unopposed magnet 10. Thus, an unopposed magnet that would ordinarily have a measurable magnetic field of four to six inches extending outward from a pole can have a beam extending five to seven feet outward from the pole. The focused magnetic beam 5 extends along the alignment axis 15 beyond the magnetic field that would occur if each magnetic field of the beam assembly were combined into a single magnetic field, such as would happen if each of the magnets were combined end-to-end. The direction and intensity of the beam can be altered by changing the alignment of the single opposing magnet 10, or by changing the position or strength of the magnets in the focusing magnet assembly relative to the focusing plane, or by changing the shape or configuration of individual magnets. Thus, for instance, the beam could be made to rotate around alignment axis 15 by sequentially altering the strength of each magnet in the focusing magnet assembly.

The increased magnetic field of the embodiment depicted in FIG. 1 can be demonstrated by its physical effects. For instance, an unopposed magnet 10 that can lift a ferric object at a distance of approximately one inch can lift the same ferric object through a distance of approximately six inches when coupled to a magnetic assembly comprised of two pairs of opposing magnets as is depicted in FIG. 1. The same assembly **can cause cathode tube distortions at a distance of approximately two feet, can make electronic systems inoperable at a distance of approximately six inches, and can double the performance of an inductor at a distance of approximately eight inches.**

In another example of the physical effects of an embodiment such as that depicted in FIG. 1, a VanDeGraaff generator with a spark potential of approximately three quarters of an inch from its bell can be placed between an assembly of north opposing magnets and an assembly of south opposing magnets, the north opposing magnets located eight inches from the bell, and the south opposing magnets located five feet from the bell, with the bell located one foot from its base. This configuration will produce a large spark from the VanDeGraaff to the south opposing magnets, indicating the **potential for the present invention to perform electron transfer through a distance.**

In alternative embodiments, various numbers of magnets or opposing magnet pairs can be arranged around the alignment axis 15 to focus the magnetic beam 5. For instance, three opposing magnets could be used instead of the four opposing magnets depicted in FIG. 1. Alternatively, a greater number of magnets or magnet pairs can be arranged offset to the focusing plane to alter the focus or strength of the magnetic beam 5. In yet another embodiment, a plurality of focusing magnet assemblies can be disposed along the alignment axis in a plurality of focusing planes.

Referring now to FIG. 2, two alternative embodiments of the present invention are depicted. First, a coil 60 comprised of a conducting material, such as copper, is disposed within a magnetic beam 5. An unbalanced capacitor 65 is coupled in series with the coil 60 and a voltmeter 66. Unbalanced capacitor 65 can be an electrical device such as the electrical device disclosed in U.S. patent application Ser. No. 08/144,814, by Boyd Bushman, abandoned, now issued as a continuation-in-part as **U.S. Pat. No. 5,637,946**, which is incorporated herein by reference. Voltmeter 66 is any conventional voltmeter capable of measuring an electric current, such as an alternating current. Movement, and even just the presence of objects, through the beam produces an AC voltage in coil 60 which can be detected by unbalanced capacitor 65 and measured by voltmeter 66.

Alternatively, a pin array 70 disposed in the magnetic beam 5 can also be used to measure disturbances, such as movement through the magnetic beam, which cause an AC voltage in pin array 70 that can be measured by voltmeter 66. Pin array 70 is any device such as the device disclosed in U.S. patent application Ser. No. 08/144,814, by Boyd Bushman, abandoned, now issued as a continuation-in-part as U.S. Pat. No. 5,637,946, which is incorporated herein by reference. Alternatively, any other means of measuring a disturbance through a magnetic field can be used.

Referring now to FIG. 3, a coil 80 comprised of a conducting material, such as copper, is depicted disposed around single unopposed magnet 10. An electric power source, such as an AC generator 85 supplies an alternating current to coil 80 at a variety of frequencies. The strength of the magnetic beam 5 varies according to the frequency of the alternating current through coil 80 due to the magnetic field created by coil 80. Thus, a magnetic pulse beam is generated according to the frequency of the current passing through coil 80. When the frequency of the AC current is high, such as ten to the fifteenth power hertz, the magnetic pulse emitted simulates the effect of a destructive electromagnetic pulse. In alternative embodiments, coils can be disposed around each magnet or around the magnet assembly as a whole to create a magnetic field and pulse according to the frequency of a current applied to the coil.

The present invention provides several technical advantages related to the application of a magnetic field. For instance, by focusing a magnetic field, the present invention allows for a decrease in the size of magnets used in commercial devices. Thus, in commercial applications such as where a magnet is used to increase the efficiency of an inductor, the present invention allows for greater miniaturization with smaller magnets than would be allowed with the magnetic field of an unfocused magnet. Where the present invention is used with electromagnets, such as for the lifting of ferric materials, a smaller electric power source can be used to create a lifting magnetic force.

US5982180

Metal detection system and process using a high voltage to produce a visible electrical discharge

The apparatus includes an electrical circuit for producing a high voltage at a high frequency with very little current and an elongated and electrically insulated electrical conductive member coupled to the circuit for producing an electrical discharge when in close proximity to a metal object in the ground. The electrical circuit is capable of producing 50,000 volts and higher. In using the apparatus, the electrical conductive member may be moved to scan the ground over a metal object to obtain an image of the shape of the metal object.

US5420588
Wave Attenuation

A radar cross-section reduction system utilizes a charging device for creating a high positive DC static potential on an object such as an aircraft. The charging system is mounted to the object so that this DC potential would be applied to the outer skin or surface of the object. The charging system includes Van de Graaf generators located in housings attached to the object. Each Van de Graaf generator has two pulleys about which a belt is rotated. One of the pulleys and the belt are nonconductors, while the other pulley is a conductor. This results in a buildup of positive charges at one end of the belt and negative charges at the other end. The negative charges are picked off and applied to a ground section. The positive charges are picked off and applied to a collector. The collector is in electrical continuity with the outer structure of the object. Negative dissipators attached to the ground section dissipate the excess negative charges during flight. Positive dissipators may be selectively switched into engagement with the skin to dissipate the positive charge on the skin prior to landing.

US5542247
Apparatus Powered Using Laser Supplied Energy

A method and apparatus are providing for converting energy into thrust, and directing the thrust to move an object. The apparatus includes a chamber having air disposed therein, a pulsed laser for converting an energy source into light pulses, and a lens for receiving the light pulses and directing the light pulses toward a focal point within the chamber. Each light pulse converges in a region which is proximate to the focal point and causes molecules within the air which are at the region to disassociate. Disassociation of the molecules generates pressure waves which provide thrust for powering the object to move.

US5680135
Radiation Communication System

An aircraft has an exhaust flame or plume which can be modulated to communicate. A sound emitter is mounted to the aircraft for emitting acoustic waves into the exhaust plume. An encoder will control the emitter at selected digital sequence to provide a digital message. The flame or plume will radiate at a frequency range of interest depending on the type of aircraft. The sound waves cause the frequencies to change from a continuous spectrum to a spectrum which has a much lower amplitude. A detector remotely located from the aircraft will detect radiation. It filters frequencies outside of the frequency range of interest. It will discriminate between the modulated pattern and the continuous pattern. This output provides the digital code that was encoded by the encoder. A decoder will decode the message for the recipient.

US5637946
Thermally Energized Electrical Power Source

An electrical device functions as a thermally energized DC power source. The device has a base plate of conductive metal. A number of electrode points protrude upward from the base plate, terminating in a sharp edge. A collection plate of conductive metal is positioned above the sharp upper edges of the electrode points. The gap between the electrode points and between the collection plate and the electrode points is electrically insulated. An electrical potential exists between the base plate and the upper collection plate while the device is at and above room temperature. The potential difference increases as the temperature increases.

Build a Crystal Shortwave Radio

This project combines two popular themes from radio history—crystal radios and shortwave (SW) listening. It's designed from scratch by our non-resident engineer Walter Heskes.

Despite all of the advances in modern electronics, there are thousands of crystal sets in daily use throughout the world. The fidelity of tone and clarity of crystal rectification are hard to beat. What's more, crystal sets are absolutely free! A crystal receiver is powered solely by the radio waves that it pulls from the air.

We dubbed this inexpensive radio the "EconOceanic" in honor of the legendary Zenith TransOceanic family of shortwave radios. It tunes the AM broadcast band, from .5 MHz to 1.6 MHz, and most of the shortwave band, from 1.7 MHz up to about 17 MHz.

There's plenty of SW activity in these bands, so you'll hear lots of different voices, a mix of languages, and even music. In addition to powerhouse stations such as the BBC, you'll also hear non-commercial amateurs, some of whom broadcast using the dits and dahs of International Morse Code. And don't forget to set your wristwatch by the precise WWV time signals. They appear at exact multiples of 5.0 MHz across the SW bands. Listen for the calibration beeps and periodic time announcements.

We hope you enjoy this project. If you build an EconOceanic, send some email to let us know how it worked out. Walter can be reached at walterh@interworld.com.

Building Instructions

You're eager to start assembly, but a few minutes of preparation will help this project go smoothly. Here's how to get started.

Printing Instructions

Before you lay hands on any parts, print out this page and all of the diagrams in the following table.

Cabinet Decal	Component Layout
Coil Selector Circuit	Tuner/Detector Circuit
Coil Winding Diagram	Antenna Bracket Assembly

The large diagrams are designed to print on a standard 8.5 x 11-inch sheet of paper. Most of them are oriented horizontally for easier reading online. Choose your printer's "landscape" mode for the horizontal diagrams, to make sure they'll print on one sheet.

Be sure that your printer is set to print at a 1-to-1 ratio, so that the cabinet decal and layout diagram are the correct size.

Parts and Tools

We recommend getting *all* of the parts you need before you start assembly. Nothing is more frustrating than getting halfway through a project, then having to wait several days for some missing part to arrive in the mail.

The following parts list gives part numbers and sources for all major parts, plus some notes on particular items.

Most of the parts you need to build the EconOceanic Crystal Shortwave Receiver are available through Radio Shack. Two exceptions are the big tuning capacitor and the little trimmer capacitor. The big tuning capacitor can be obtained from Antique Electronic Supply. Or, you may be lucky enough to have a spare tuning capacitor in your junkbox. The small trimmer capacitor is available from All Electronics, allcorp@allcorp.com, 1-800-826-5432. Some notes on specific parts appear after this list.

Quantity	Component	Type	Part No.	Price
1	Diode	1N34A [1]	Radio Shack 276-1123	$ 1.19 pkg 10
1	Variable capacitor [2]	Dual-range: 40-460 pF/30-156 pF	AES CV300-145	$3.50
1	Trimmer capacitor	6-40pF	All Elect. VCAP-14	$1.50
1	Ceramic capacitors [3]	10 pF, 22 pF, 50 pF	Radio Shack 272-801	$2.49 pkg 100
2	Phone jacks	1/8-inch diameter	Radio Shack 274-251	$2.49 pkg 3
1	Speaker terminal strip [4]	Spring-loaded	Radio Shack 274-315	$ 1.29
4	Rotary switches	2-pole, 6-circuit	Radio Shack 275-1386	$1.69
1	Slide switch	DPDT	Radio Shack 275-407	$ 1.29 pkg 2
1	Enameled wire [5]	#22 and #26	Radio Shack 278-1345	$3.99 pkg 3
3	Knobs	1.0-inch diameter	Radio Shack 274-416	$2.29 pkg 4
2	Knobs	0.75-inch diameter	Radio Shack 274-415	$ 1.89 pkg 4
1	Project box	7.5" x 4.33" x 2.22" plastic	Radio Shack 270-224	$ 3.49
1	Cardboard tube	From paper towel roll		
1	Epoxy glue [6]	JB Weld or similar		
1	Household glue [7]	Elmer's Glueall or similar		
1	Rubber feet [8]	Heavy-duty self-stick	Radio Shack 64-2342	$ 1.49 pkg 8
Optional				
1		Battery powered	Radio Shack 277-	$11.99

	Amplified speaker [9]		1008	
1	Headphones	2,000-ohm	AES P-A466	$14.50
1	Antenna	6-foot telescoping	Radio Shack 270-1408B	$4.99
1	Fuse holder clips [10]	(for antenna swivel)	Radio Shack 270-739A	$ 1.19 pkg 2

Notes

[1] Any type of germanium diode will work.

[2] A variable air capacitor can be scrounged from any old AC/DC superheterodyne AM radio. Use the RF section for the wide range (40-460 pF) and the oscillator section for the narrow range (30-156 pF)

[3] Bags of ceramic capacitors are available in large quantities from Antique Electronic Supply and Radio Shack. These capacitors will work fine, but if you buy them in bulk, you may need to identify them using their markings or by reading them with a capacitor meter.

[4] The speaker terminal strip is used for the ground and antenna connections, as explained in the building instructions.

[5] Enamel-coated wire is available from Radio Shack and other suppliers. Radio Shack part no. 278-1345 is a package of three spools of enameled wire in the following sizes: #22 (gold enamel), #26 (green enamel), and #30 (red enamel), all for $3.99. If you don't see it on display, find it in the catalog and point it out to the clerks so they will order it for you.

[6] It's not critical which type of glue you use to fasten the metal frame of the tuning capacitor to the plastic surface of the instrument panel. Epoxy glue (JB weld or similar) will work, and so will silicon-based glues and perhaps others.

[7] Elmer's Glueall will work to coat the coils as you wind them. Or, you can use polyurethane varnish to seal the coils.

[8] Use four rubber feet to support the cabinet and two rubber feet to fasten the coil to the inside panel of the cabinet.

[9] If you choose to use an amplified speaker (highly recommended), use a short coaxial cable terminated with 1/8" plugs on both ends to connect the EconOceanic output to the speaker.

[10] One of the fuse holder clips is modified to form a swiveling support for the antenna mast, as explained in the building instructions. To fasten the antenna mast assembly to the cabinet, you'll also need a small screw, rubber washer, metal washer, lockwasher, and nut. If you don't have those items lying around somewhere, your house is cleaner than ours!

The tools that you'll need are pretty simple—a soldering iron, drill, wire stripper (or knife), screwdriver, and pliers or crescent wrench.

Preparing the Cabinet

Let's go! The first major step is to drill mounting holes for the controls in the plastic cabinet. The entire radio is mounted to the front panel, making it easy to remove for modifications or simply for showing a friend your handiwork.

The Component Layout Diagram and Cabinet Decal show you where to drill holes in the cabinet front panel for the components. Carefully trim the decal to fit the cabinet, then punch or cut holes in the decal where indicated. Glue on the decal. Don't put any glue under the places where you'll be drilling holes. Using a scribe or sharp knife, and guided by the scribe marks on the decal, make a little guide hole in the exact center of each place to drill. Using a sharp knife, carefully trim away the paper from each hole, so the drill won't tear the paper.

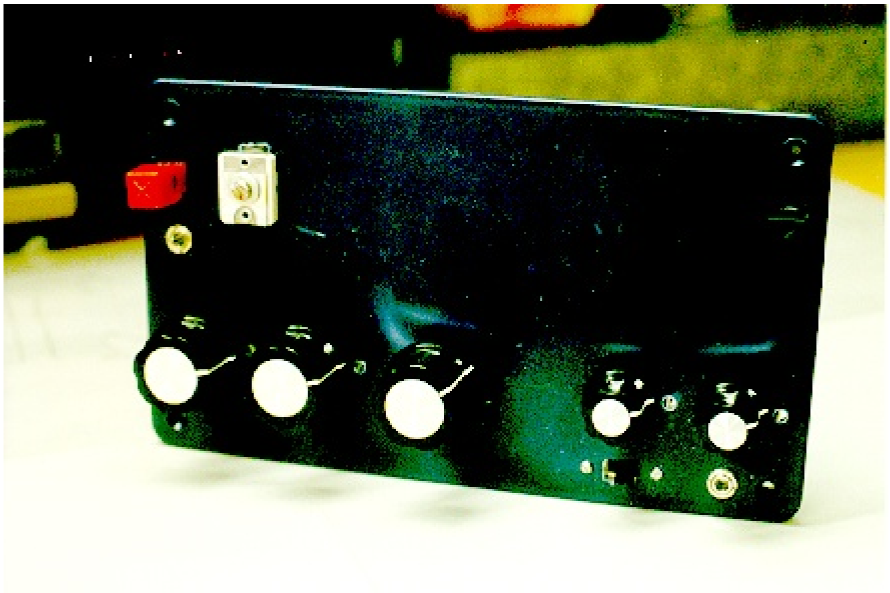
Regarding the decal, not all printers are created equal, so make sure it's printed at the right size before gluing it on. At the correct size, the decal measures 7.5 inches wide (horizontally) at the trim lines. If you can't get it to print correctly, you can try loading the image into a graphics program such as Photoshop or Paintshop Pro and resizing it for a new printout. The component layout diagram gives exact measurements for the holes, in any case.

Before you drill any holes, check clearances by placing the actual knobs in place atop the diagram. Now drill the holes. Drilling plastic is fast and easy. Wear protective eyegear to guard against flying fragments of plastic.

If you'd like to protect the paper decal against dirt and wear, spray on a thin coat of clear lacquer or poly finish, then set it aside to dry. A more permanent solution would be to have it laminated beforehand at a local copy shop.

Finally, mount the components in the positions shown in the component layout diagram. Pop the front panel into the case and admire your work. From the outside, this project looks almost finished—all that's left is to build the radio that goes inside!

Below are front and rear views of the author's prototype, after mounting the controls on the front panel. (This prototype did not have a decal.)



Building the Switchable Coils

Switchable coils are a unique feature of the EconOceanic. With many old shortwave radios, changing bands required you to unplug one coil and plug in another. With the EconOceanic, you simply turn switches to change coils in or out. That's more convenient, and it reduces wear and tear on the coils.

Making a Rigid Coil Form

In the EconOceanic, all of the BC and SW coils will be wound on a single core. The first step is to get something to wind your coils on. A standard roll of paper towels comes on a 1 5/8-inch diameter cardboard tube, which is just right.

Although you can wind the coils on a single tube, it's a good idea to reinforce the tube with a second stiffening layer, to help resist the tension of the wire as you wind the coils. To create the reinforcement, get an extra cardboard tube, slice it down its length, and remove a 3/8-inch wide strip along the cut, thus reducing its diameter. (Remember that this inner tube has to fit inside another tube of the same original diameter.) Apply a thin layer of Elmer's Glueall to the entire outer surface of the inner tube and insert it through the outer tube. Let it expand and gently press the tubes together to spread the glue. Hold them together for a couple of minutes, then set them aside for the glue to dry. Now you have a single, thick core.

Marking Eight Sections on the Coil Form

This design requires precise winding, which will be easier if you take a moment to mark your core with lines along its length to indicate its halves, quadrants, and eighth-sections. (In other words, draw eight equally-spaced straight lines, each one going the entire length of the tube.) When you need to wind a coil of 22 3/4 turns, you'll know exactly where to stop during the 23rd turn.

The more accurate your coils, the better they'll work. A coil with the wrong number of turns provides the wrong inductance and will not tune the desired range of frequencies.

Winding Your Coils

It's time to start winding, a task that requires care. Here's a little trick that simplifies the process. As you wind each coil, it helps to apply a thin layer of Elmer's Glueall to hold the most recently wound section together. Otherwise, the wires tend to spring apart (if that happens, you have to rewind the coil from scratch.) Wind about 10 turns, hold them tightly in place with your thumb, apply a pea-sized glob of glue to the wound section, and spread it with the middle finger of your other hand. Work the glue between the coils to encapsulate them. The thin layer dries in a few seconds and you can quickly continue winding. It's a technique you can develop pretty quickly. By the time you've wound all 101.5 turns of the big broadcast (BC) band coil, you'll feel like an expert!

Wind one coil at a time, following the Coil Winding Diagram. Use a full spool of wire when you start winding the big BC coil. It can be heartbreaking to run out of wire just before you reach the end.

Leave 10 inches of extra wire at each end of each coil. It is better to have extra length now which can be trimmed away later. These ends are the leads that you'll connect to the other components. Mark each lead wires using a little flag of masking tape (for instance, "250 uH Antenna" and "250 uH Ground"). The markers will simplify hookup later on.

The chart below lists the number of turns and size of wire to use for each coil. This radio tunes five bands. Each band requires a pair of windings: a small primary and a larger secondary.

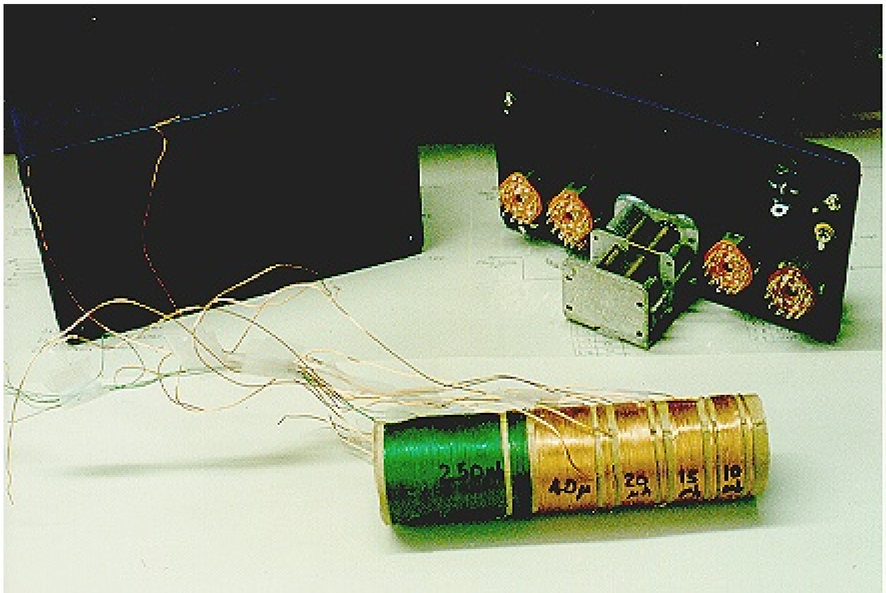
Coil Section	Number of Turns	Wire gauge
250uH primary	17	26
250uH secondary	102	26
40uH primary	5.6	22
40uH secondary	33.5	22
20 uH primary	3.3	22
20 uH secondary	19.7	22
15 uH primary	2.3	22
15 uH secondary	14.5	22
10 uH primary	2.2	22
10 uH secondary	11.1	22

Each winding must be separated by a small gap from the next. Leave a 1/8-inch gap between windings for the 250uH, 40 uH, and 20 uH coils. Leave a 1/16-inch gap between the 15 uH and 10 uH coils.

Winding can be tedious, but it doesn't pay to rush. If you do this part correctly, you'll have a good-performing radio that performs virtually maintenance-free for many years.

When all the winding is done, check your work to make sure that everything is tight and secure. If necessary, apply more glue where needed. You can also apply a thin coat of clear varnish, if desired, for a more finished appearance.

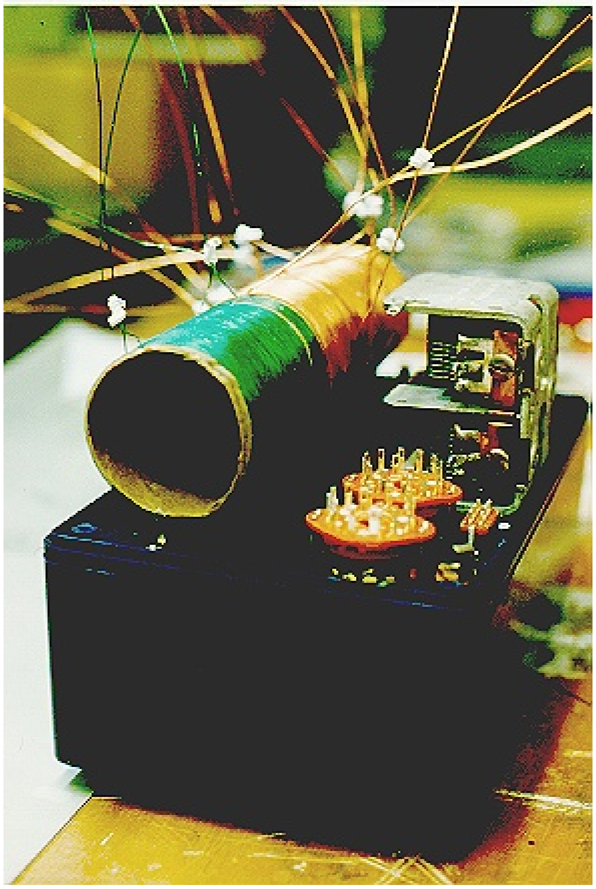
This photo shows the author's prototype coil, ready for mounting.



Mounting the Coils

Mount the coil assembly to the inside surface of the front panel. Check for adequate clearance when the tuning capacitor is fully open. Leave about 1/8-inch minimum clearance between the open rotor and the coil assembly. The rotor and coil must not touch. Mark the center of the coil form and mount self-sticking rubber feet to the centerline of the coil form. The feet serve as standoffs from the front panel, providing some clearance under the coil through which you can pass wires.

This photo shows the author's prototype coil mounted inside the front panel, which was placed upside down on the cabinet for the photo. Note the little plastic ties used to keep related leads together.



Wiring the chassis

Before you start hooking up components, take a few moments to study the schematic diagrams carefully. The ones you'll be using are the Coil Selector Circuit and Tuner/Detector Circuit.

Connecting Wires for Antenna and Ground

Let's start by attaching lead wires to the antenna and ground connections. These are shown in the Coil Selector Circuit. Connect wires to both antenna input jacks, the antenna trimmer, and the ground input jack. Check your connections for correctness and solder them.

Connecting Coils to the Coil Selector Switch

Identify the pinouts of the rotary switches. Use an ohmmeter to check continuity across the switch circuits and note the position of the switch pointer as each circuit is made. When you are certain you understand how the switch circuits are opened and closed, start wiring the antenna coils to the antenna coil selector switch.

Measure the length of wire needed to span the distance from the coil to the lug at the rotary selector switch. Straight runs are fine. Minimize the number of right angle bends, since those can reduce circuit sensitivity. Trim the coil takeoff leads to approximately 10 inches.

Using a razor blade or fine sandpaper, carefully scrape the enamel coating off each lead wire before you thread it through a lug on the rotary switch. Be careful not to break the fragile lead as you bend it around the lug.

Checking Coil Connections

Do not solder any connections until you have checked for proper continuity through each switch circuit and its coil. Refer to the Coil Selector Circuit as needed while checking your work.

Wiring Tuning Coils

After all the antenna coils are wired to the rotary switch, you can begin wiring the tuning coil circuits, referring to the Tuner/Detector Circuit diagram. Again, check for continuity through each switch circuit and its coil. Do not solder until all leads have been properly wired.

Next, connect the leads of the tuning coil to the tuning capacitor.

Connecting Capacitors

Connect the ceramic capacitors to the bandspread rotary switch. This is tedious work because the capacitor leads are short and the spacing between adjacent rotary switch lugs is small. Work slowly and carefully.

Connect the leads to the bandspread hi-lo selector switch. Since the DPDT switch has two circuits and only one circuit is needed, you can wire across both circuits if that makes wiring a bit easier for you. Or, use a larger SPDT switch.

Making Final Connections

Connect the 1N34 diode to the phone jack and to the band capacitor selector switch. Polarity is not important.

Connect the capacitors and leads to the tuning capacitor selector switch.

Connect the leads to the output jack.

Final Check and Soldering

You're almost done! Before soldering any connections, follow the schematic diagrams and recheck every connection for continuity. Correct any wiring errors that you find. When you're sure that everything's hooked up correctly, solder each lead.

Mounting the Antenna

The EconOceanic can use many different kinds of antennas. You'll get the best reception from a long outdoor antenna, of course. In many areas, however, you can get respectable performance from the 6-foot telescoping antenna listed in the Parts List.

To mount the telescoping antenna, modify one of the fuse holder clips as shown in the Antenna Bracket Assembly diagram. The clip forms a swiveling support for the antenna mast. To fasten the antenna mast assembly to the cabinet, you'll also need a small screw, rubber washer, metal washer, lockwasher, and nut.

Using Your Radio

Your EconOceanic radio is completely assembled. Now for the exciting part—using it! This description may sound harder at first than it really is in practice. We'll go through the process simply because it's a little more involved than using

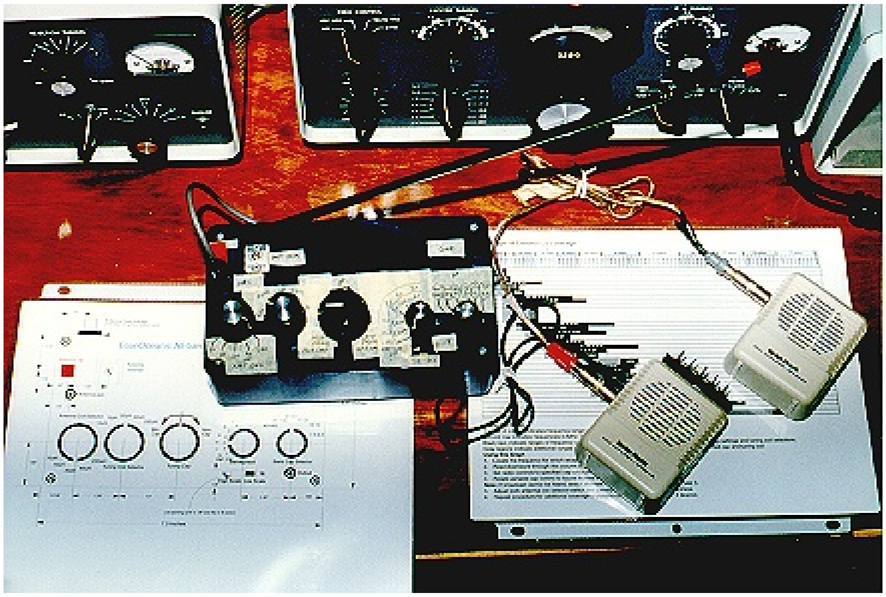
Step 1. Connect antenna and ground. Connect your antenna and ground wires to the appropriate terminals on the front panel. If you are using the telescoping antenna, it is already connected, of course.

Step 2. Connect listening device. Plug in your 2000-ohm headphones or, better yet, use Radio Shack's amplified speaker so everyone can listen at the same time. The amplified speaker is a transistorized amplifier connected to an internal speaker. It also has a 1/8-inch phone jack, allowing you to listen without disturbing others.

The author connected the output of the amplified speaker to a good quality high fidelity speaker. Later, the author added a second amplified speaker to the radio. The second stage amplifies the weakest signals to audible levels and easily fills the room with sound. This diagram explains the connections:

Connect this . . .	To this
EconOceanic output jack	Input jack of first amplified speaker
Output jack of first amplified speaker	Input jack of second amplified speaker
Output jack of second amplified speaker	Hi-fi speaker

This photo shows the author's prototype, with temporary labels on the panel, connected to two amplified speakers in series.



Step 3. Choose a Station. Depending upon the time of day and your location in the world, you can tune across the SW bands and listen in on broadcast activity. Some of the SW bands are more active in the evening hours, while others operate during the day.

Consult a schedule of shortwave broadcasts and note the time of day and frequency at which a desired broadcast will occur. Schedules are published in SW hobbyist magazines available at better newsstands. You can also find loads of schedule information on the Web, such as this resource page at SWLing.com. Another good resource is the book World Radio TV Handbook.

Step 4. Look up tuner settings. Use the Bar Graph of Continuous Coverage to find the correct capacitor and coil settings to tune in the desired frequency. Print this chart using your printer's landscape mode so that it will fit on a single 8.5x11-inch sheet.

As you become more familiar with the principles of resonance, you will find that you can tune the receiver to the desired frequency by thinking about the resonance formula and selecting coils and capacitors according to the following logic:

Low-frequency Broadcasts	High-frequency Broadcasts
Most capacitance	Least capacitance
Longest coil	Shortest coil

For example, to tune the AM broadcast band, you would select your longest coil (250uH) and your biggest capacitor setting (460 pF). Similarly, to tune the highest shortwave frequencies, you would select your shortest coil (10uH) and your smallest capacitor setting (7 - 9 pF).

It's possible to receive the same broadcast signal with different combinations of coils and capacitors. The best combination is the one at which the incoming signal is loudest. Experiment and learn the best settings. You can also combine dissimilar primary and secondary coils to receive radio signals. That is, you can set the antenna coil to 250uH and the tuning coil to 20uH and you will receive SW signals. This occurs because of the inductive coupling effects of the multiple coils on the same coil form.

Remember that the tuning coil alone determines the frequency at which radio signals will be received. The tuning coil resonates with the tuning capacitor. The antenna coil merely feeds the incoming radio waves to the tuning coil. Enjoy this advantage of mounting several adjacent coils on the same core.

Step 5. Turn the antenna coil selector switch to a desired primary coil.

Step 6. Rotate the tuning coil selector switch to the associated secondary coil.

Step 7. Turn the band capacitor selector switch to a desired setting. Now the band is selected.

Step 8. Rotate the tuning capacitor to select a broadcast signal within the selected band.

Step 9. Starting at the lowest setting of the "low" bandspread scale, adjust the bandspread switch for maximum broadcast signal loudness.

Step 10. If you are using the amplified speaker, adjust the volume to a comfortable setting. If you are using a pair of unamplified, 2000-ohm headphones, there is no loudness control.

Step 11. Log your settings. On a sheet of paper, write the time of day, the settings of your selector switches, and a description identifying the source of the broadast signal. For example, you might write:

```
9 P.M. EST, 20uH A coil, 20uH T coil, 13-19 pF, Radio Havana (Cuba) 8.9 MHz.
```

Logging your reception reports will help you locate your favorite radio broadcasts. Documenting your work also adds a hint of substance and credibility to your DX sessions. Above all, have fun!

Theory of Operation

This block diagram shows each stage of the EconOceanic crystal shortwave receiver. Click on each component to read more about it.

```
   Aerial
      |
      |
Antenna coil-->Tuning coil-->Tuning capacitor-->Detector-->Output
      |
      |
Earth ground
```

Aerial

The aerial's job is to capture electromagnetic waves from all sources and directions and funnel those charges into the antenna coil. The loudness of received signals is directly proportional to the height and length of the aerial. Mount the aerial as high as possible, preferably outdoors. A single wire 100 feet long makes an ideal aerial. The EconOceanic design provides for two antenna connections: one 1/8-inch phone jack and a spring-loaded clip (originally intended for fastening hi-fi speaker cables).

If your antenna is mounted outdoors, you should disconnect it whenever there is any chance of lightning in your vicinity.

Antenna coil

The antenna coil is the primary winding of the pair of coils that make up the antenna-tuning transformer. It is a fraction (1/6) of the number of turns that make up the tuning coil. The secondary coil multiplies the electrical field created by the antenna coil.

Earth ground

The earth ground connection effectively extends the antenna into the earth, which contains electrical signals. Keep the ground wire as short and straight as possible. There may be some sensitivity loss if the excess ground wire is coiled into a loop. Use either a metal cold water pipe that is buried at least several feet in the ground or an electrical conduit that is similarly buried or grounded. You can usually make a satisfactory ground connection using the screw that fastens the cover plate to an electrical outlet box.

Tuning coil

The tuning coil is the inductor which, in series with the tuning capacitor, determines the resonant frequency of the receiver according to the formula: **frequency = 1/[2*pi*sqroot(L*C)]**. Wind your coil carefully and space it close to the antenna coil (about 1/8" apart) to tune the specified frequencies.

The amount of coupling is directly proportional to the distance between the windings. If you slide the windings far apart, there is little coupling and a narrow resonance peak (e.g., 100 KHz). If you move the windings closer, there is more coupling and a broader resonance peak (e.g., 200 KHz). A broader resonance peak will mean less selective tuning; that is, several stations will be heard simultaneously at one tuner setting. Experiment, if you wish, with spacing your coils. For example, try 1/4-inch between the primary and secondary windings and test your design for selectivity. Have fun as you learn.

Tuning capacitor

The tuning capacitor is the variable component in the "tank" circuit which comprises the coil and the cap. By varying the capacitance, you can change the resonant frequency of the receiver within the limits of the coil inductance and the total capacitance available in the variable capacitor.

Detector (diode)

In this radio, a diode serves as the detector, separating the fluctuating direct current (containing the voices and music of the broadcast) from the amplitude-modulated, radio-frequency, alternating-current carrier wave that was transmitted from the radio station antenna. The direct current generated by the detector will drive the output device.

Output (headphones or amplified speaker)

The output device changes the electrical energy in the detector circuit into mechanical energy that moves air against our ears to create sound. For satisfactory sound output, this needs to have an input sensitivity of a few millivolts and an input impedance of a few thousand ohms, such as a pair of 2000-ohm headphones or Radio Shack's amplified speaker (part no. 277-1008). Don't try to use a permanent-magnet speaker, such as one scrounged from an old radio. Permanent-magnet speakers require more DC energy than a crystal set can generate.

If you completed this project and enjoy using your EconOceanic, please drop us a line and share your experiences. Walter's email address is walterh@interworld.com.

This radio construction project, including all descriptions, diagrams, photos, and the underlying electronic design, is published here for the noncommercial use of radio hobbyists. Building a crystal radio set

Updated Tuesday 3rd July 2007

For many of the original teenagers, home-built crystal radios gave them their first contact with the world beyond their bedrooms. Here, Fraser Robertson describes how to make your own.

A crystal set is the most basic type of radio receiver. It is capable of receiving AM (amplitude modulated) transmissions, which are generally found on the long, medium and short wave bands.

The magic of the crystal set is that no power source is required; a tiny fraction of the transmitted signal provides sufficient power for the signal to be heard. What follows, while listing the parts you'll need, isn't a step-by-step how to guide, as part of the fun

Crystal Radio

Transmitters

in building a crystal set is experimenting and optimising performance.

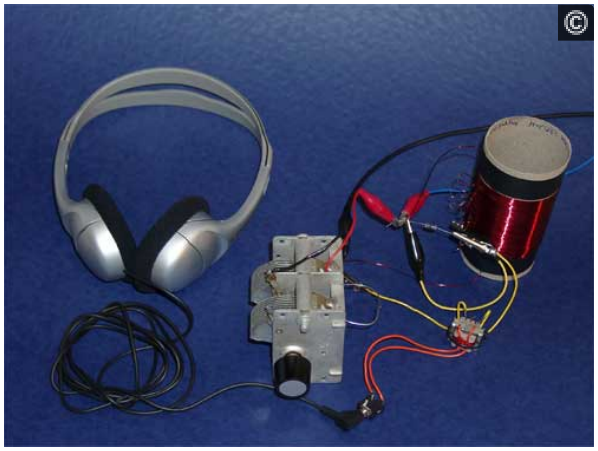
Aerial

Unless the crystal set is very close to the transmitter, an aerial, (or antenna) will be required in order to receive a big enough signal for the crystal set to work. Generally the aerial will be a length of wire, which should be as long and as high as possible.

A wire strung from an upstairs window to a distant tree will work well; say 30 metres long and seven metres high. The type of wire is not critical, but PVC covered stranded copper wire of about 2 milimetres diameter will work well.

If the wire is too thin it may break in the wind, and/or birds may fly into it; too thick and it will sag under its own weight.

The aerial should be insulated at each end from its support, a short length of washing line or other non-conductive cord can be used. An effective aerial will produce about one tenth of a volt radio frequency (RF), which will result in good reception.



Earth

An earth connection is required to complete the aerial circuit. This can be a length of copper pipe driven into the ground, or a length of buried un-insulated wire.

38

Why do we need a Large Hadron Collider? [38]

39

Anti-Matter [39]

As with the aerial, a better earth connection will improve reception. It is possible to connect to a metal heating or water pipe, but **this is not recommended on safety grounds** should there be an electrical fault. For the same reason, **the mains earth** should not be used.

When the crystal set is not in use the aerial should be connected directly to the earth connection. This will prevent any possible static build up on the aerial.

Tuned circuit

The aerial and earth are connected across a parallel tuned circuit. The purpose of this is to select the wanted station.

A simple crystal set will not have good selectivity so if two strong signals are received on nearby frequencies it will not be possible to separate them.

The tuned circuit comprises a coil (inductor) and a capacitor, which is usually variable for tuning. Pre-wound ferrite rod coils can be bought, or you can wind your own: for example, for medium wave, 100 turns of 0.5 milimetre enameled copper wire wound on a toilet roll or similar sized non-metallic former, twisted/tapped every ten turns.

The greater number of turns, the longer the wavelength (lower frequency), so a coil for long wave will require more turns. If using a pre-wound ferrite rod, ignore the small link windings.

An air spaced variable capacitor (with a value around 500 picofarad) removed from an old radio is ideal, or alternatively a small polyvaricon capacitor as used in transistor radios.

Variable capacitors often have two or more capacitors in one (known as **ganged**), in which case these can be connected together to increase the maximum capacitance (lower the tuning frequency).

Some variable capacitors also have FM (VHF) tuning sections included, which can be ignored. If a variable capacitor is not available, a fixed capacitor can be used (e.g. 150 picofarad - 470 picofarad), with the tuning adjusted by changing taps on the coil. In which case, taps every five turns would be useful.

Detector

The purpose of the detector is to recover the audio signal (waveform) from the radio frequency signal. Early crystal sets used an adjustable ‘cats whisker’ detector, but a germanium or Schottky diode is now used, examples are OA90, OA91, BAT81, BAT85, 1N34, 1N5711. Any one of these can be used.

Silicon diodes, (such as 1N4148) do not work as well due to their higher forward voltage drop. Modern zero gate threshold voltage FETs can be used for better sensitivity, although these are not readily available in small quantities. The detector diode is polarized (directional), but in the crystal set circuit it does not matter which way round it is connected.

Headphones

Traditional crystal sets used sensitive high impedance headphones, typically several thousand Ohms, which are hard to obtain now. A crystal earpiece can be used, or a sensitive pair of walkman style headphones (usually 32+32 Ohms) connected through a transformer (e.g. type LT700) to raise the impedance. Low impedance headphones will ‘load’ the tuned circuit excessively.

Look for headphones with a high sensitivity figure, for example 115 decibels - a higher number indicates higher sensitivity; CPC AV03626 106 decibel headphones work well. Be aware that a higher quoted decibel specification does not always guarantee higher sensitivity in practice.

Note that if a crystal earpiece is used, a resistor (such as a 47k Ohms) may need to be connected across it to provide a DC path for the detector diode.

Construction

The fine detail here is left to the builder. Component leads can be soldered, or twisted together, or 'crocodile clips' can be used to make connections.

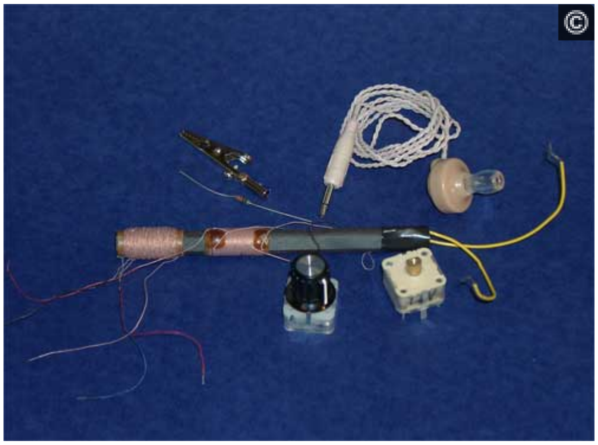
The diagram above, and the photograph at the top of the page, offers some guidance. **You can download a larger pdf of the diagram by clicking here**[4].



This photograph shows examples of alternative suggested parts. The components can be lashed together initially for experimentation, then connected more permanently and housed in any suitable enclosure once the crystal set is working.

Typical performance and troubleshooting

In the UK it will normally be possible to pick up two or three stations on medium wave, and/or BBC Radio 4 from Droitwich on long wave. If nothing at all is heard check:

- that all connections are sound, and ensure the enamel insulation on coil wire has been removed by being scraped off where connections are made
- that the correct connections for each component have been used
- that the tuning capacitor vanes are not bent and touching together.

If you get weak reception it may be that you need to improve the aerial / earth connections, or try a different pair of headphones.

Building a crystal radio set

Updated Tuesday 3rd July 2007

For many of the original teenagers, home-built crystal radios gave them their first contact with the world beyond their bedrooms. Here, Fraser Robertson describes how to make your own.

Share this article

Author

A crystal set is the most basic type of radio receiver. It is capable of receiving AM (amplitude modulated) transmissions, which are generally found on the long, medium and short wave bands.

The magic of the crystal set is that no power source is required; a tiny fraction of the transmitted signal provides sufficient power for the signal to be heard. What follows, while listing the parts you'll need, isn't a step-by-step how to guide, as part of the fun in building a crystal set is experimenting and optimising performance.

Aerial

Unless the crystal set is very close to the transmitter, an aerial, (or antenna) will be required in order to receive a big enough signal for the crystal set to work. Generally the aerial will be a length of wire, which should be as long and as high as possible.

A wire strung from an upstairs window to a distant tree will work well; say 30 metres long and seven metres high. The type of wire is not critical, but PVC covered stranded copper wire of about 2 milimetres diameter will work well.

If the wire is too thin it may break in the wind, and/or birds may fly into it; too thick and it will sag under its own weight.

The aerial should be insulated at each end from its support, a short length of washing line or other non-conductive cord can be used. An effective aerial will produce about one tenth of a volt radio frequency (RF), which will result in good reception.

Earth

An earth connection is required to complete the aerial circuit. This can be a length of copper pipe driven into the ground, or a length of buried un-insulated wire.

As with the aerial, a better earth connection will improve reception. It is possible to connect to a metal heating or water pipe, but **this is not recommended on safety grounds** should there be an electrical fault. For the same reason, **the mains earth** should not be used.

When the crystal set is not in use the aerial should be connected directly to the earth connection. This will prevent any possible static build up on the aerial.

Tuned circuit

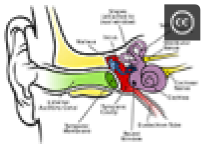
The aerial and earth are connected across a parallel tuned circuit. The purpose of this is to select the wanted station.

A simple crystal set will not have good selectivity so if two strong signals are received on nearby frequencies it will not be possible to separate them.

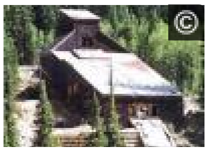
The tuned circuit comprises a coil (inductor) and a capacitor, which is usually variable for tuning. Pre-wound ferrite rod coils can be bought, or you can wind your own: for example, for medium wave, 100 turns of 0.5 milimetre enameled copper wire wound on a toilet roll or similar sized non-metallic former, twisted/tapped every ten turns.

Sir Bernard Lovell: An appreciation

Discover superstrings



What is sound?



Inside the science - radioactivity

The greater number of turns, the longer the wavelength (lower frequency), so a coil for long wave will require more turns. If using a pre-wound ferrite rod, ignore the small link windings.

An air spaced variable capacitor (with a value around 500 picofarad) removed from an old radio is ideal, or alternatively a small polyvaricon capacitor as used in transistor radios.

Variable capacitors often have two or more capacitors in one (known as **ganged**), in which case these can be connected together to increase the maximum capacitance (lower the tuning frequency).

Some variable capacitors also have FM (VHF) tuning sections included, which can be ignored. If a variable capacitor is not available, a fixed capacitor can be used (e.g. 150 picofarad - 470 picofarad), with the tuning adjusted by changing taps on the coil. In which case, taps every five turns would be useful.

Detector

The purpose of the detector is to recover the audio signal (waveform) from the radio frequency signal. Early crystal sets used an adjustable ‘cats whisker’ detector, but a germanium or Schottky diode is now used, examples are OA90, OA91, BAT81, BAT85, 1N34, 1N5711. Any one of these can be used.

Silicon diodes, (such as 1N4148) do not work as well due to their higher forward voltage drop. Modern zero gate threshold voltage FETs can be used for better sensitivity, although these are not readily available in small quantities. The detector diode is polarized (directional), but in the crystal set circuit it does not matter which way round it is connected.

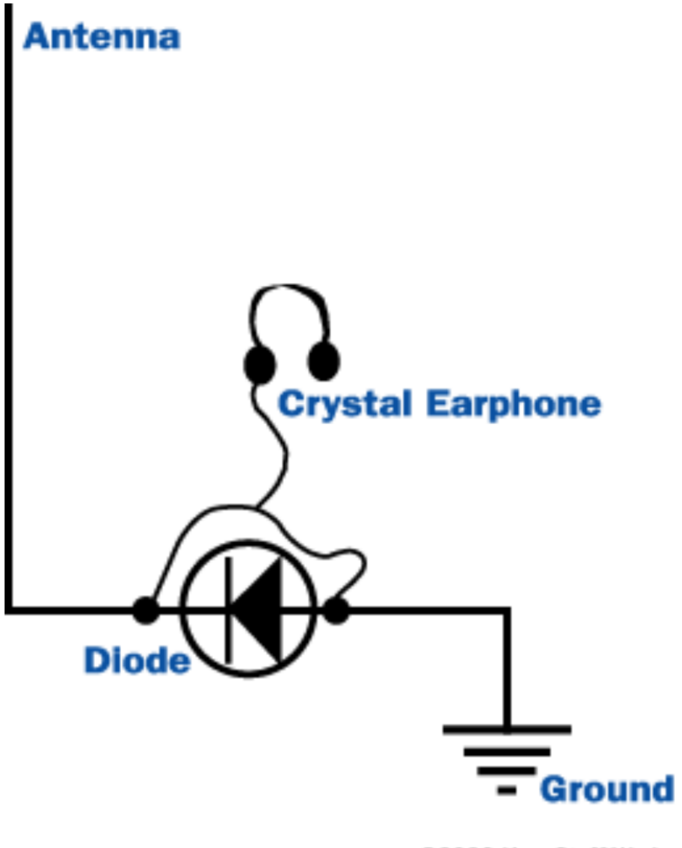
The Simplest AM Receiver



©2000 How Stuff Works

In the case of a strong AM signal, it turns out that you can create a simple radio receiver with just two parts and some wire! The process is extremely simple -- here's what you need:

- **A diode** - You can get a diode for about $1 at Radio Shack. Part number 276-1123 will do.
- **Two pieces of wire** - You'll need about 20 to 30 feet (15 to 20 meters) of wire. Radio Shack part number 278-1224 is great, but any wire will do.
- **A small metal stake** that you can drive into the ground (or, if the transmitter has a guard rail or metal fence nearby, you can use that)
- **A crystal earphone** - Unfortunately, Radio Shack does not sell one. However, Radio Shack does sell a Crystal Radio Kit (part number 28-178) that contains the earphone, diode, wire and a tuner (which means that you don't need to stand right next to the transmitter for this to work), all for $10.

You now need to find and be near an AM radio station's transmitting tower (within a mile/1.6 km or so) for this to work. Here's what you do:

Free-Power AM Radio Receiver

Strange as it may seem, this transistor broadcast-band radio receiver "steals" power from one station to give to another! The principle is basic: By tuning the battery-section antenna coil (L2) to the strongest broadcast station on the band, diode X1 can rectify the rf and convert it into DC current. Naturally, the closer you are to a strong station, the more current the "radio battery" section of your radio receiver will be able to supply. Once you have found this spot, the DC current is passed on to power the transistor circuit which acts as a genuine receiver, with the full tuning it affords. See Fig. 18 and Table 18.

The basic consideration is a good antenna and ground, the latter preferably being made to a water pipe or solid external ground composed of a pipe driven at least 4 feet into moist earth. This procedure not only ensures maximum signal pickup for the radio-battery portion of the circuit, but also provides best results for the GE-2 receiver circuit.

Once completed, just tune the radio battery as explained in the first paragraph and calibrate your receiver by adjusting L1 so that the bottom of the band occurs when C1 is fully meshed. If you have a local broadcast station operating near 540 kHz, this simplifies things tremendously. Once the calibration procedure is complete, forget entirely about adjusting L1 and do all your listening by tuning C1.

17

Solar TV Reception Booster

Here is a versatile rooftop TV reception booster that will add a full 18 dB of gain to the incoming TV signals at your receiver. This means no more ghosts, clearer pictures, and perhaps even reception of a distant station you could not get before. Best of all, this gadget is powered by an inexpensive solar cell that will virtually run forever without requiring replacement. Additionally, the circuit is designed with a charger circuit and reserve pack.

You can build it as is, or only include as much as you would like. For example, if you break the circuit where the X's are indicated, your booster will thrive entirely off its solar battery. If you break it at the two Y's, the solar cell charges a 4½-volt battery pack during the day so the booster will work just as well at night as in direct sunlight. If you include all the circuit (taking into account the indoor AC supply shown), you can occasionally recharge the 4½-volt pack just in case you have had a protracted period of rain or overcast weather which prevented the solar cell from sending its energy down to the reserve battery.

Construction is not complicated, but since you are dealing with both vhf and uhf signals, you will have to keep all leads extremely short and direct. In fact, you would do best to cram the parts close together so as to cut down on the length of interconnecting wires. Looking at the schematic, you will note that Q1 must be grounded; this is no problem; however, since the HEP-3 comes with four leads instead of the regular three. Turning the transistor upside down, you will notice an arrangement of leads as shown and identified in Fig. 17.

Fig. 17. Solar TV reception booster.

Take care in constructing your coils that you duplicate exactly those turns and techniques recommended in Table 17.

Once complete, you can test out your booster by hooking it to the TV set and placing a lit 60-watt lamp bulb in rather close proximity to M5. As the lamp is turned on, you should get a much-improved picture. Adjust the best reception on all channels by tuning L4 and the coupling between L1 and L2. Now mount at the TV antenna, positioning M5 for best sunlight hits.

Hint: Leave the AC plug plugged in at all times. It will not draw power until you throw switch S1 onto "charge."

Tapping into Natural Radio

Figure 1 shows suggestions on utilizing a tree as an antenna. For HF, I suggest using the tallest tree available. Perhaps shorter trees would be better for VHF-UHF as in the 1990 *73* article discussed above—or perhaps not. As with any outside antenna it is wise to utilize some form of lightning protection.

RADIO RIDDLES

Last month:

I said, "Let's say that we could stain some radio waves, frozen at one moment in time, with some kind of dye so that we could actually see them. Of course we can't do this, except in our imagination. But if we did, how would the waves appear to us?"

For the area occupied by the waves at any one instant in time we would be trying to visualize the variations in the signal's electrical-field strength, and the reversals in field orientation (showing when the RF current changes direction of flow twice each cycle). This wouldn't look like a wavy line, or a sine wave graph as is represented in most texts on radio.

One way to imagine seeing the frozen waves is to envision that the space which the radio waves fill will show a darker shade of gray where their field strength is more intense, and a lighter shade where their field strength is weaker. For simplicity, let's consider only direct-wave propagation with no reflections or other impediments to the wave's travel between the transmitting antenna and receiving antenna.

In the space between the two antennas we would see bands of differing shades of gray oriented at right angles to the wave's direction of travel. There would be darker bands, less dark bands just next, even less dark bands next till a relatively light shade of gray was reached. Then somewhat darker bands, then even darker bands, and on to produce a sort of zebra-skin look. The darkest bands would be a half wavelength apart as would the lightest ones.

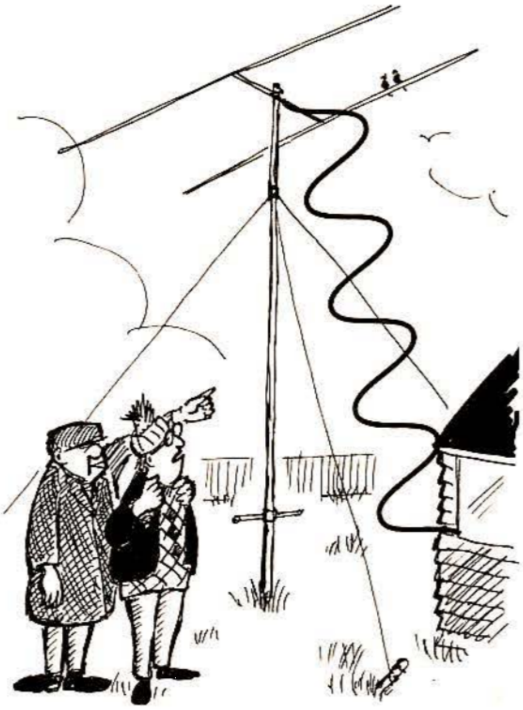
If we added a green tinge to our gray to indicate one orientation of the electrical field, and a red tinge for the field's other orientation then, starting at the middle of a darker band there would be greenish gray for a half wavelength along the direction of wave travel, a reddish gray for the next half wavelength, and so on.

Of course this picture is an over-simplification. For instance, we haven't talked about the wave's magnetic field, the polarization of the wave, or the spherical shape of the wavefront. But this simplified picture does cover the basic idea of radio waves in space.

This Month:

Let's say that, instead of freezing the waves, we had the advanced eyes and brains of some specialized android so that we could actually watch radio waves zip along on their 186,000 miles per hour flight from the transmitting antenna to our receiving antenna? How would those rascals look then?

You'll find an answer for this month's riddle, and much more, in next month's issue of *Monitoring Times*. 'Til then Peace, DX, and 73.



"You know, I thought those were classic standing radio waves until I read Clem Small's column this month. Now, I don't know what the heck they are!"

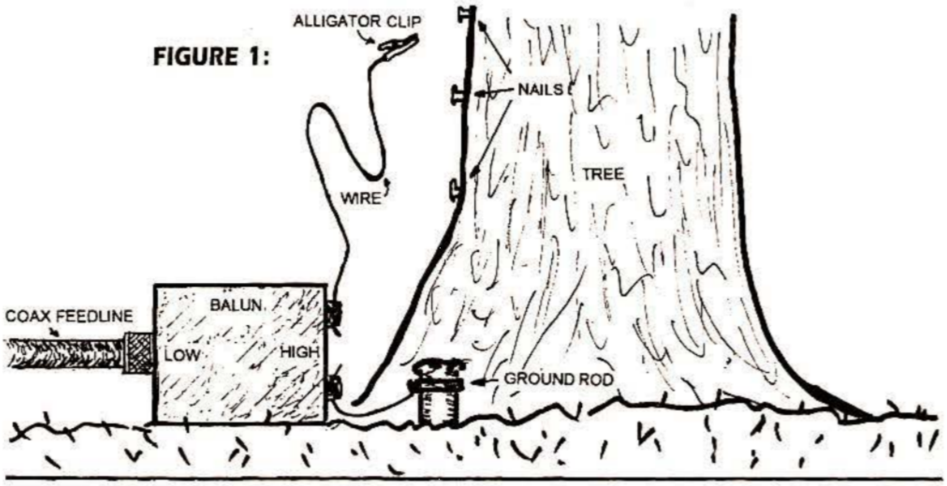
Prehistoric Radio!

FIGURE 1:



Connecting a feedline to a tree antenna. Nail small, thort, thin nails into the tree about every two or three feet, up to 10 or 15 feet high. Connect the clip to the various nails until best results are achieved. The balun is a 4:1 ratio or higher, high side to the tree.

If you've been following the "Below 500 kHz" column, you know that natural phenomena right here on earth have been producing, transmitting, and receiving radio signals since time began. Lightning bolts, and some other mighty reactions in nature, produce great amounts of electromagnetic radiation in the light, heat, and the radio portions of the electromagnetic-wave spectrum. Lightning discharges from tropical storms in particular are continually producing wide-band radio waves that propagate worldwide. You receive these signals as bothersome static noise on the LF, MF, and on HF bands.

Weak-signal operators who do moon-bounce work are only too well acquainted with the radio signals which our own sun transmits. These noisy signals can totally mask over moon-bounce signals when the sun and moon are both in the same direction from moon-bouncer's antenna. Radio waves known as "cosmic noise" are continually bombarding our antennas with radio signals generated by natural reactions occurring in galactic space. As a matter of fact, the discovery that the source of this particular radio noise lay outside our solar system marked the beginning of radio astronomy. In radio astronomy, naturally occurring radio signals from space are studied in an attempt to learn more about the cosmos.

OK, so there were radio signals before we were around to know about it, but what about the reception of those waves? Who received those signals? No person received them, but they were received by every naturally-occurring conductor to which they propagated. And, once trees evolved, they provided natural, grounded-vertical Marconi antennas to receive these waves.

Well, but where was the receiver for those antennas? The resistance of the tree's "body" was the "receiver." This resistance dissipated much of the received energy as heat rather than as sound, like the loudspeaker does in our HF receivers.

Of course, natural transmission and reception still goes on today. Have you asked the trees near your home if they have received any RF signals lately? I have. And the trees which I asked told me that they receive lots of signals—and I haven't gone off my rocker! They receive lightning-generated signals just as they have since time immemorial, and they also receive the signals which man puts onto the airwaves today.

How did I ask the trees? It's simple. I just connected a feedline to a tree, and connected the line to my receiver. I received a multitude of signals across the LF, MF, and HF bands. If I had tried other bands I would have, no doubt, received signals on those bands, too. As a matter of fact, a tall, live tree makes a decent LF-MF-HF antenna.

■ Tree-Antennas Throughout Radio's History

Old time radio expert Squires reported using trees as receiving aerials for distances of 50 kilometers. His method was to hammer a nail into the tree a few yards above the ground, and connect the receiver's antenna input connectors to the nail and to a ground.

Texanna Loomis, daughter of wireless communication pioneer Mahlon Loomis, says in her *Radio Theory and Operating* that "It has been found that a tree can be used for a receiving antenna, preferably an oak, by attaching a lead-in wire to the trunk of the tree."

Another old-time radio expert named Morecroft felt that reception came from the lead-in wire, rather than the tree itself. In my own tests I can't agree with Morecroft, because my lead-in was shielded, grounded coax, the attachment connectors to the tree were short, and the antenna performed much more like a long antenna than a short stub.

In more recent times there have also been reports of tree antennas. Cohen, in the April 1996 issue of *73 Magazine*, reports using a tree antenna on VHF and UHF with "mediocre-to-good results," but no acceptable results for lower bands. Perhaps his use of trees only 20 feet tall limited their performance on lower bands.

Also in *73* (May 1990), JA6HW and JA6AUI report using a 12 foot high tree for both transmitting and receiving on the 10 meter band with good results. Their article also says that hams used live-tree antennas in the 1930's, as did the U. S. Forces in Vietnam. In *Monitoring Times*, April 1989, Dr. Kosta reports that trees "frequently work better than conventional antennas" for television reception. In the September 1990 issue of *Monitoring Times* yours truly reports good results with a tall maple tree on LF through HF.

PAPER 53

THE LUCIFER REBELLION

LUCIFER was a brilliant primary Lanonandek Son of Nebadon. He had experienced service in many systems, had been a high counselor of his group, and was distinguished for wisdom, sagacity, and efficiency. Lucifer was number 37 of his order, and when commissioned by the Melchizedeks, he was designated as one of the one hundred most able and brilliant personalities in more than seven hundred thousand of his kind. From such a magnificent beginning, through evil and error, he embraced sin and now is numbered as one of three System Sovereigns in Nebadon who have succumbed to the urge of self and surrendered to the sophistry of spurious personal liberty—rejection of universe allegiance and disregard of fraternal obligations, blindness to cosmic relationships.

In the universe of Nebadon, the domain of Christ Michael, there are ten thousand systems of inhabited worlds. In all the history of Lanonandek Sons, in all their work throughout these thousands of systems and at the universe headquarters, only three System Sovereigns have ever been found in contempt of the government of the Creator Son.

1. THE LEADERS OF REBELLION

Lucifer was not an ascendant being; he was a created Son of the local universe, and of him it was said: "You were perfect in all your ways from the day you were created till unrighteousness was found in you." Many times had he been in counsel with the Most Highs of Edentia. And Lucifer reigned "upon the holy mountain of God," the administrative mount of Jerusem, for he was the chief executive of a great system of 607 inhabited worlds.

Lucifer was a magnificent being, a brilliant personality; he stood next to the Most High Fathers of the constellations in the direct line of universe authority. Notwithstanding Lucifer's transgression, subordinate intelligences refrained from showing him disrespect and disdain prior to Michael's bestowal on Urantia. Even the archangel of Michael, at the time of Moses' resurrection, "did not bring against him an accusing judgment but simply said, 'the Judge rebuke you.' " Judgment in such matters belongs to the Ancients of Days, the rulers of the superuniverse.

Lucifer is now the fallen and deposed Sovereign of Satania. Self-contemplation is most disastrous, even to the exalted personalities of the celestial world. Of Lucifer it was said: "Your heart was lifted up because of your beauty; you corrupted your wisdom because of your brightness." Your olden prophet saw his sad estate when he wrote: "How are you fallen from heaven, O Lucifer, son of the morning! How are you cast down, you who dared to confuse the worlds!"

Very little was heard of Lucifer on Urantia owing to the fact that he assigned his first lieutenant, Satan, to advocate his cause on your planet. Satan was a member of the same primary group of Lanonandeks but had never functioned as a System Sovereign; he entered fully into the Lucifer insurrection. The "devil" is none other than Caligastia, the deposed Planetary Prince of

Very little was heard of Lucifer on Urantia owing to the fact that he assigned his first lieutenant, Satan, to advocate his cause on your planet. Satan was a member of the same primary group of Lanonandeks but had never functioned as a System Sovereign; he entered fully into the Lucifer insurrection. The "devil" is none other than Caligastia, the deposed Planetary Prince of Urantia and a Son of the secondary order of Lanonandeks. At the time Michael was on Urantia in the flesh, Lucifer, Satan, and Caligastia were leagued together to effect the miscarriage of his bestowal mission. But they signally failed.

Abaddon was the chief of the staff of Caligastia. He followed his master into rebellion and has ever since acted as chief executive of the Urantia rebels. Beelzebub was the leader of the disloyal midway creatures who allied themselves with the forces of the traitorous Caligastia.

The dragon eventually became the symbolic representation of all these evil personages. Upon the triumph of Michael, "Gabriel came down from Salvington and bound the dragon (all the rebel leaders) for an age." Of the Jerusem seraphic rebels it is written: "And the angels who kept not their first estate but left their own habitation, he has reserved in sure chains of darkness to the judgment of the great day."

2. THE CAUSES OF REBELLION

Lucifer and his first assistant, Satan, had reigned on Jerusem for more than five hundred thousand years when in their hearts they began to array themselves against the Universal Father and his then vicegerent Son, Michael.

There were no peculiar or special conditions in the system of Satania which suggested or favored rebellion. It is our belief that the idea took origin and form in Lucifer's mind, and that he might have instigated such a rebellion no matter where he might have been stationed. Lucifer first announced his plans to Satan, but it required several months to corrupt the mind of his able and brilliant associate. However, when once converted to the rebel theories, he became a bold and earnest advocate of "self-assertion and liberty."

No one ever suggested rebellion to Lucifer. The idea of self-assertion in opposition to the will of Michael and to the plans of the Universal Father, as they are represented in Michael, had its origin in his own mind. His relations with the Creator Son had been intimate and always cordial. At no time prior to the exaltation of his own mind did Lucifer openly express dissatisfaction about the universe administration. Notwithstanding his silence, for more than one hundred years of standard time the Union of Days on Salvington had been reflectivating to Uversa that all was not at peace in Lucifer's mind. This information was also communicated to the Creator Son and the Constellation Fathers of Norlatiadek.

Throughout this period Lucifer became increasingly critical of the entire plan of universe administration but always professed wholehearted loyalty to the Supreme Rulers. His first outspoken disloyalty was manifested on the occasion of a visit of Gabriel to Jerusem just a few days before the open proclamation of the Lucifer Declaration of Liberty. Gabriel was so profoundly impressed with the certainty of the impending outbreak that he went direct to Edentia to confer with the Constellation Fathers regarding the measures to be employed in case of open rebellion.

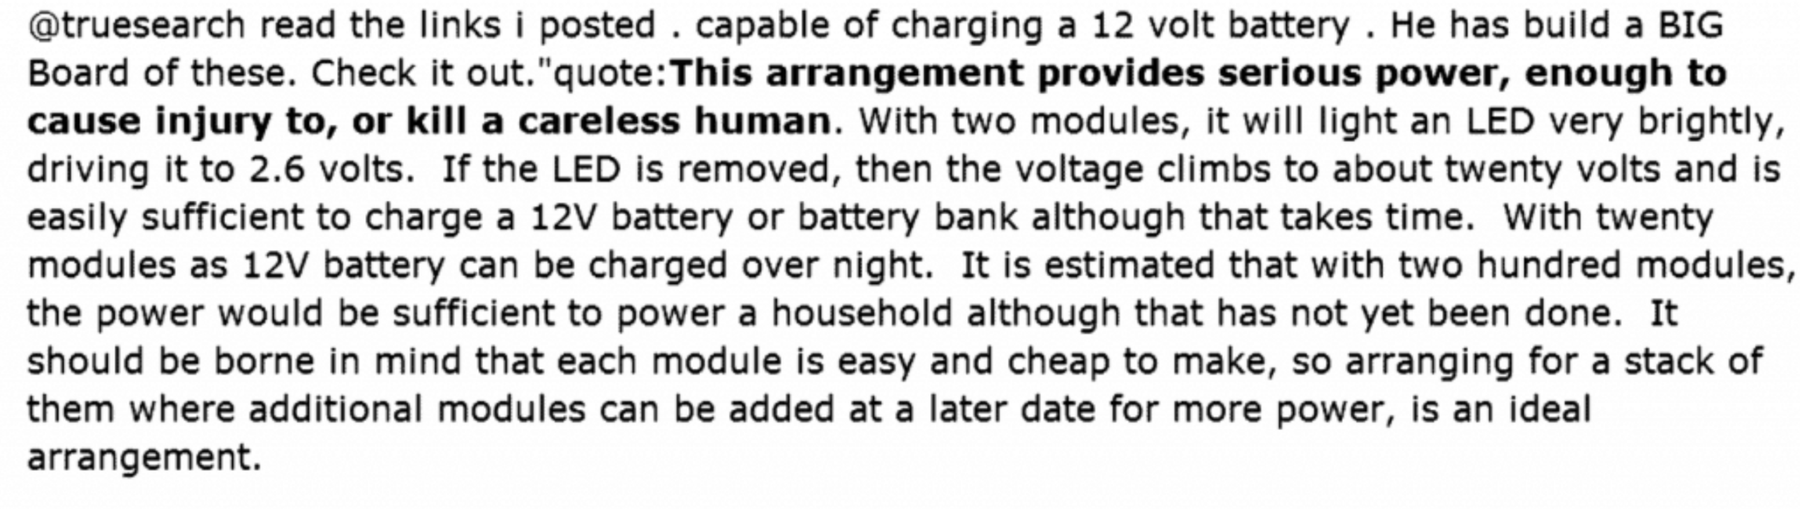
AERIAL CONNECTION
EARTH WIRE



@truesearch read the links i posted . capable of charging a 12 volt battery . He has build a BIG Board of these. Check it out."quote:**This arrangement provides serious power, enough to cause injury to, or kill a careless human**. With two modules, it will light an LED very brightly, driving it to 2.6 volts. If the LED is removed, then the voltage climbs to about twenty volts and is easily sufficient to charge a 12V battery or battery bank although that takes time. With twenty modules as 12V battery can be charged over night. It is estimated that with two hundred modules, the power would be sufficient to power a household although that has not yet been done. It should be borne in mind that each module is easy and cheap to make, so arranging for a stack of them where additional modules can be added at a later date for more power, is an ideal arrangement.

Using Fast Recovery Diodes

In order to generate more electricity, it is possible by stepping up with more diodes. To make it work properly, the type of diodes and the construction of antenna play a crucial role.

To begin with this process, let us first start setting up the antenna. In order to set an antenna properly, there are some key issues to consider.

An antenna should be made of Ferrite and a height of 30 inch rod is an ideal option to setup the antenna for receiving radio waves.

In regard to diodes, the Geranium the lowest loss diodes and a low breakdown junction voltage of ~ 0.2 - 0.4 Volts is ideal, in case you are unable to find the you may use the regular 1N4148, would just work.

A radio wave gets intercepted in areas with higher concentration and traffic congestion. In this kind of situation it is seen that each diode can pull around 30mV.

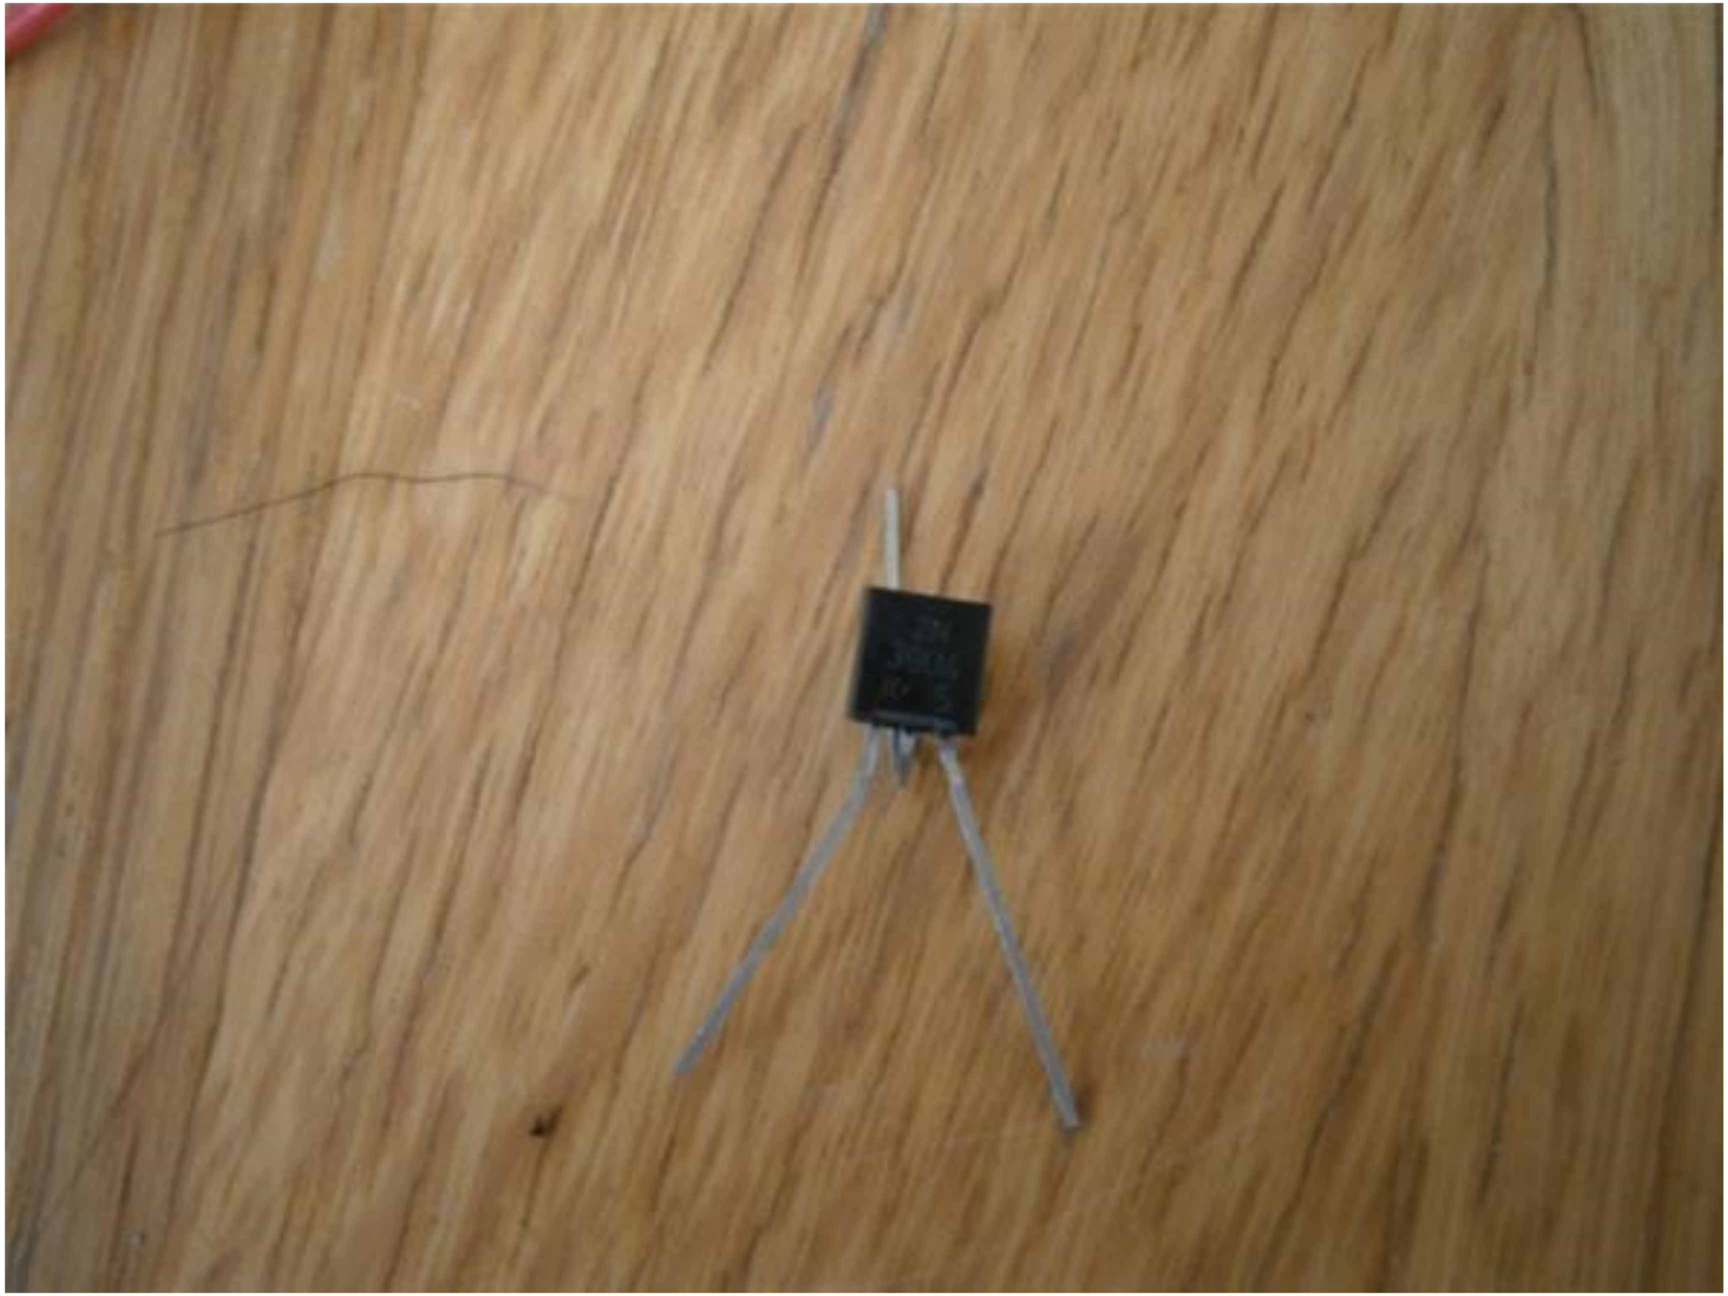
- LED
- 1k resistor
- 2n904 transistor
- Thin magnet wire
- Solder
- Soldering iron
- Battery clip
- Ferrite core
- Dead battery

Prepare the Transistor

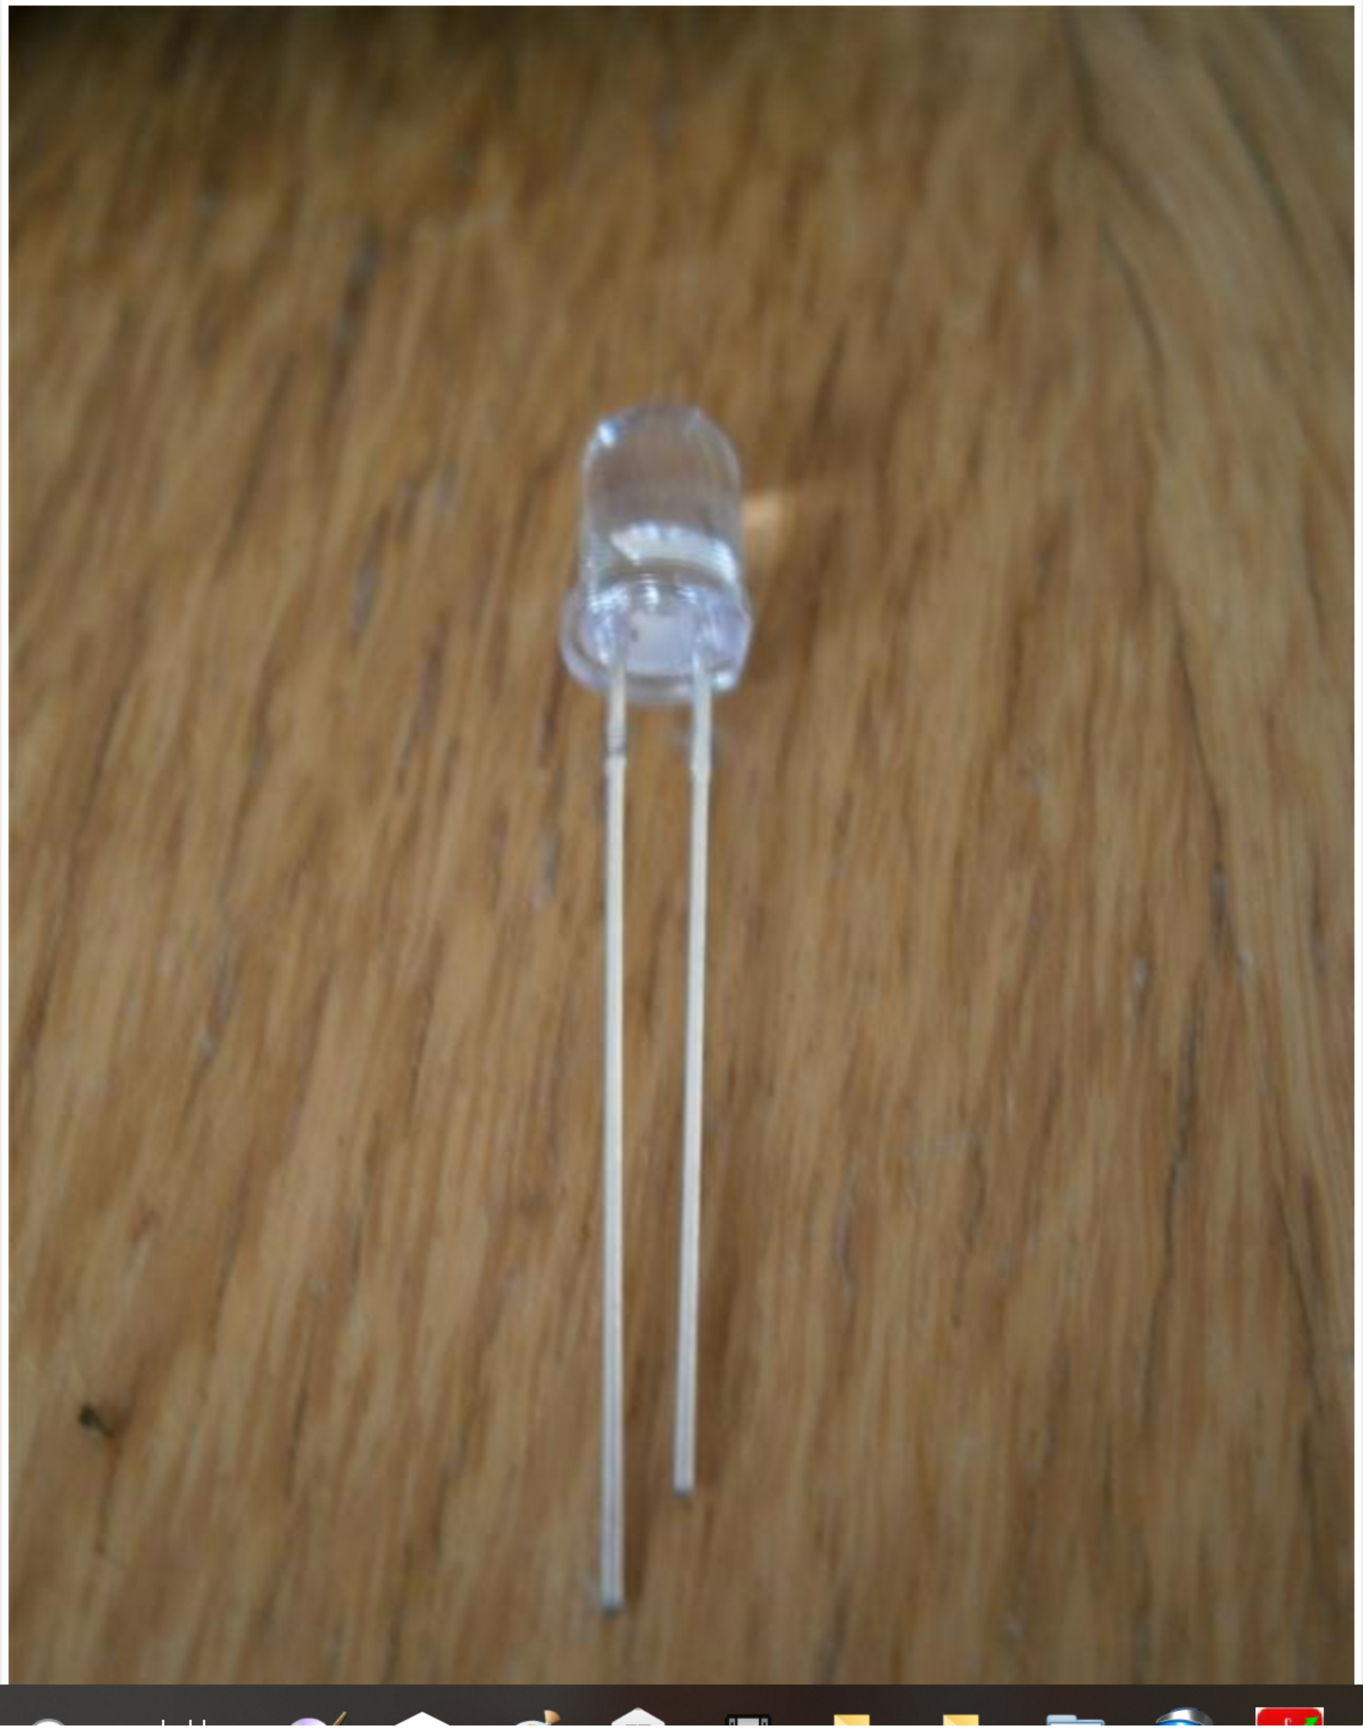
Lay the transistor on a table with the flat side facing up. Spread the pins of the transistor for easy soldering.

Bend the middle pin back and up behind the black plastic case of the transistor.

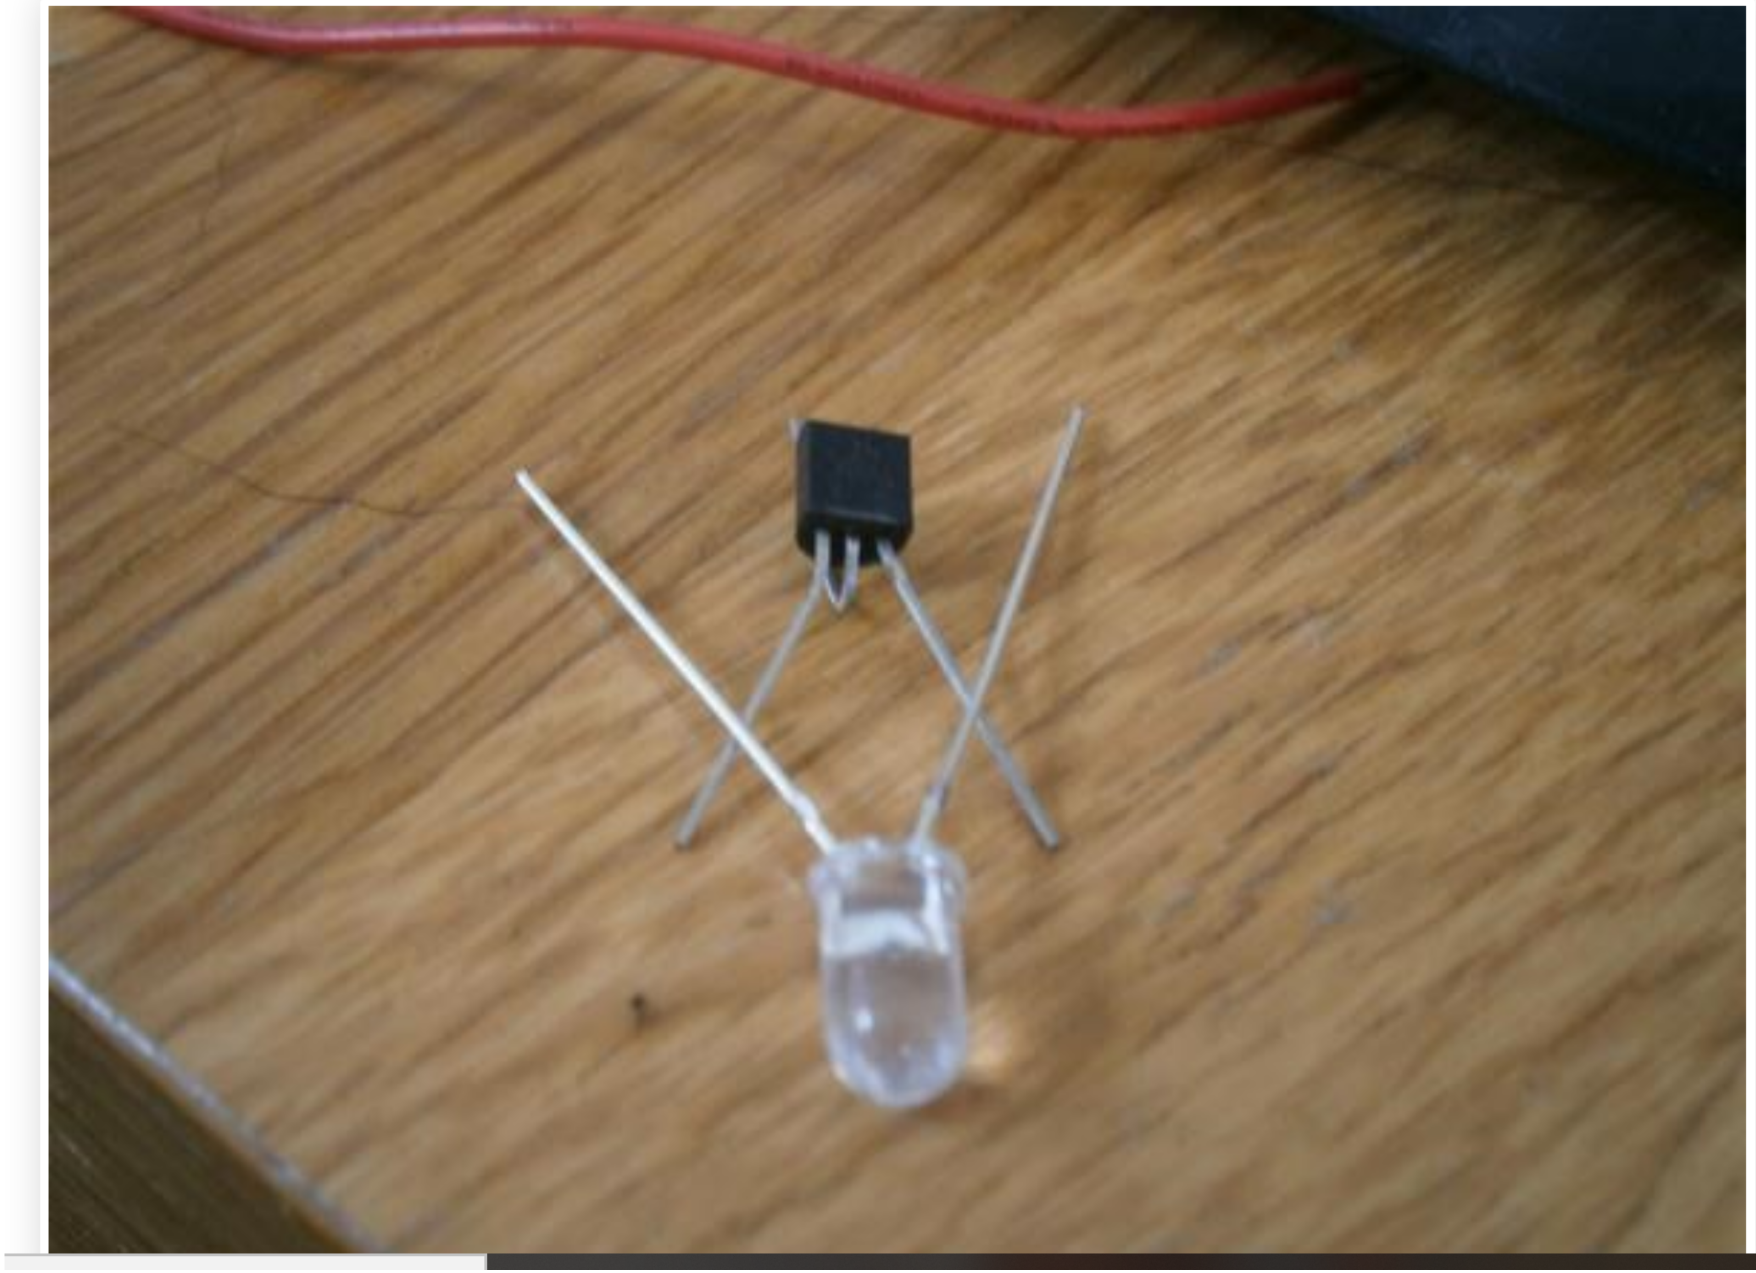


Place the LED

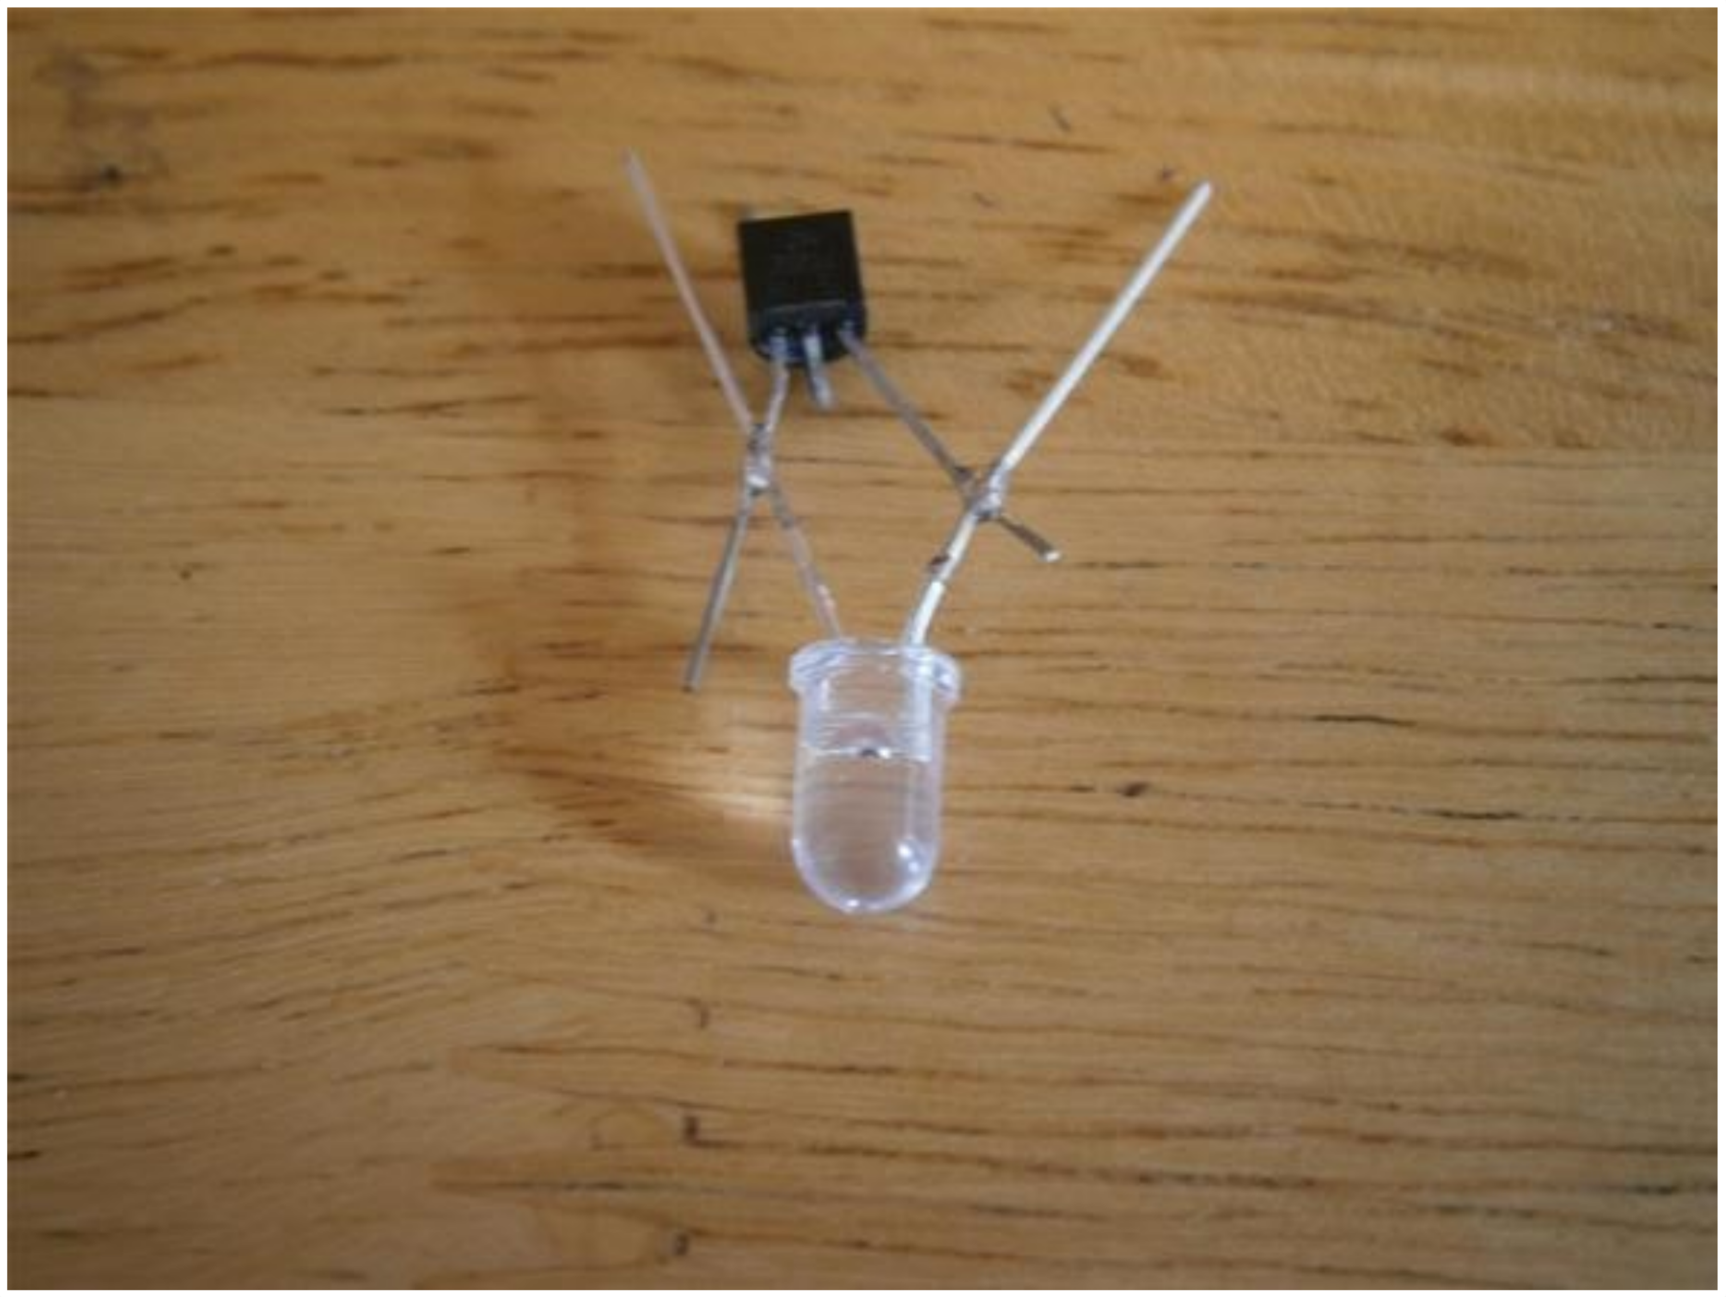
The LED is a polarized component. This means it will only work when it is facing the right way in our circuit. The positive lead of the LED is usually longer. Below, the positive lead is on the left, the shorter negative lead is on the right.



Place the LED on the transistor as shown below, with the positive side facing to the right.



Now, solder the LED to the transistor.



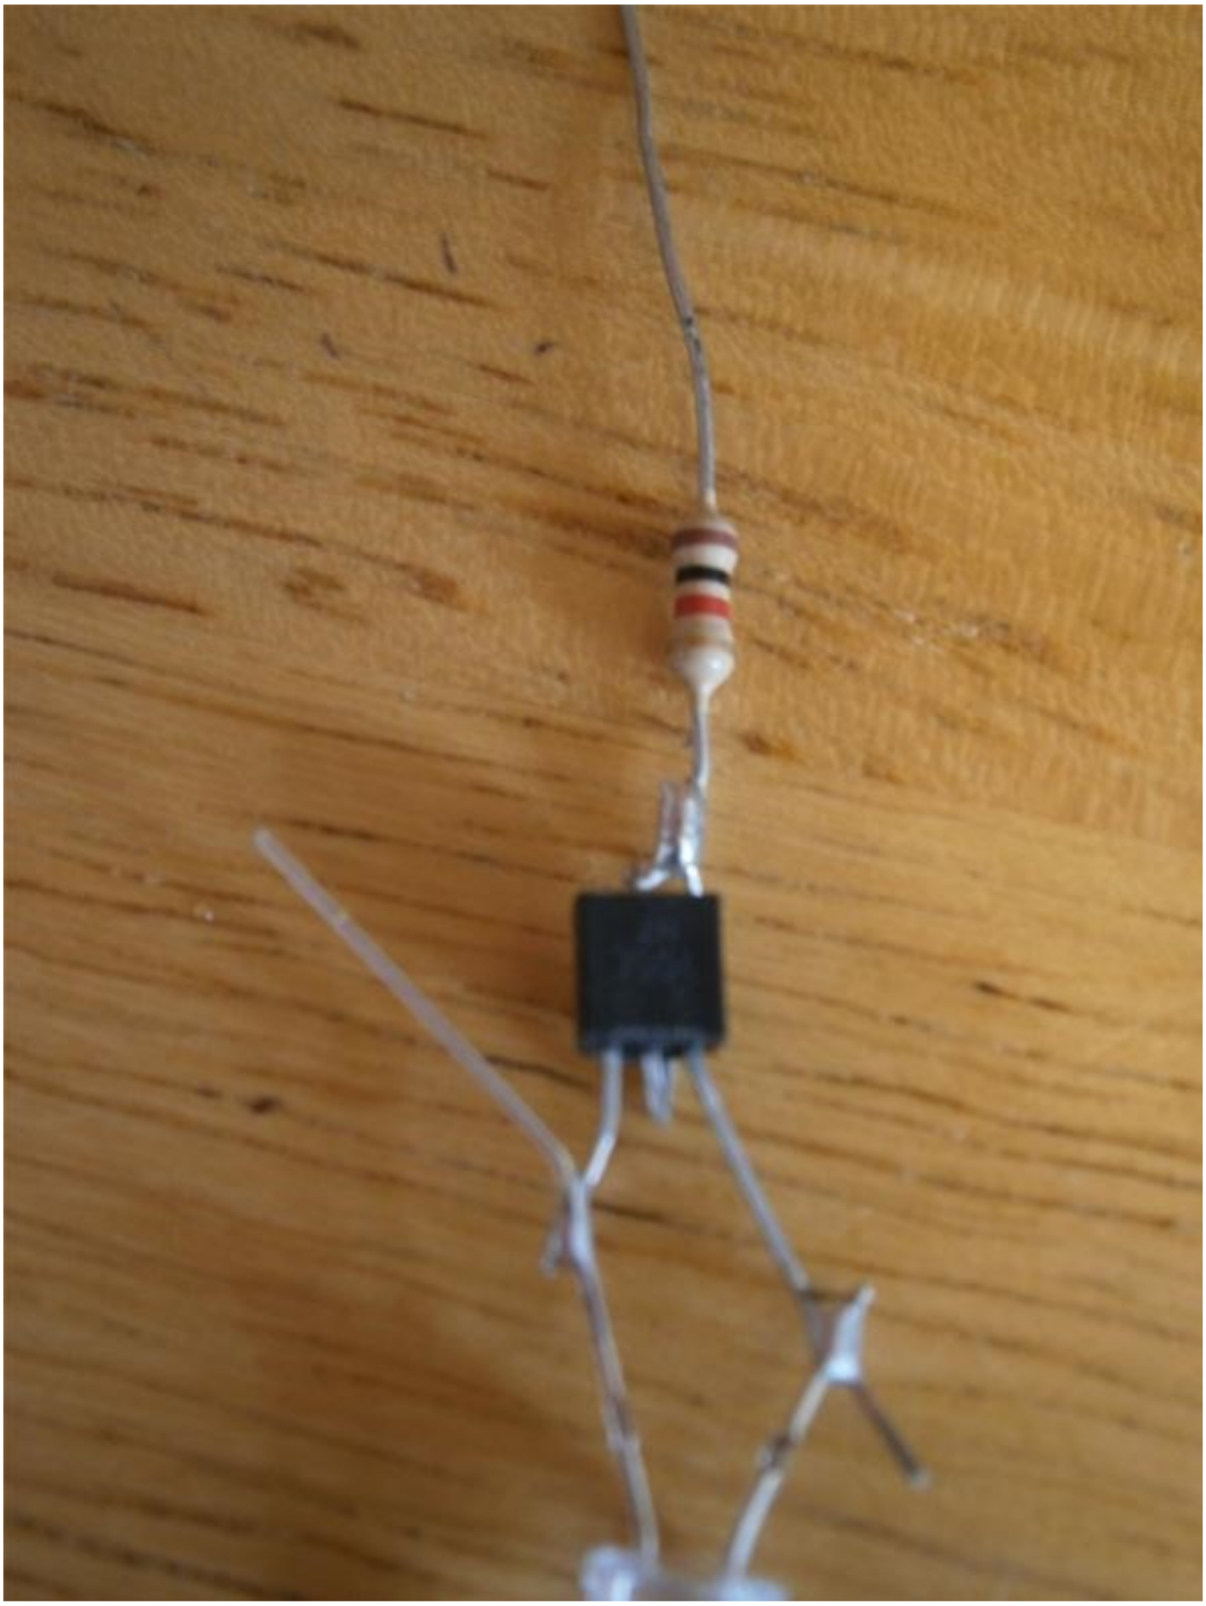
Place the Resistor

Place one end of the resistor on the middle pin of the transistor. Make sure the components stay in contact while you solder them.

Zillow®

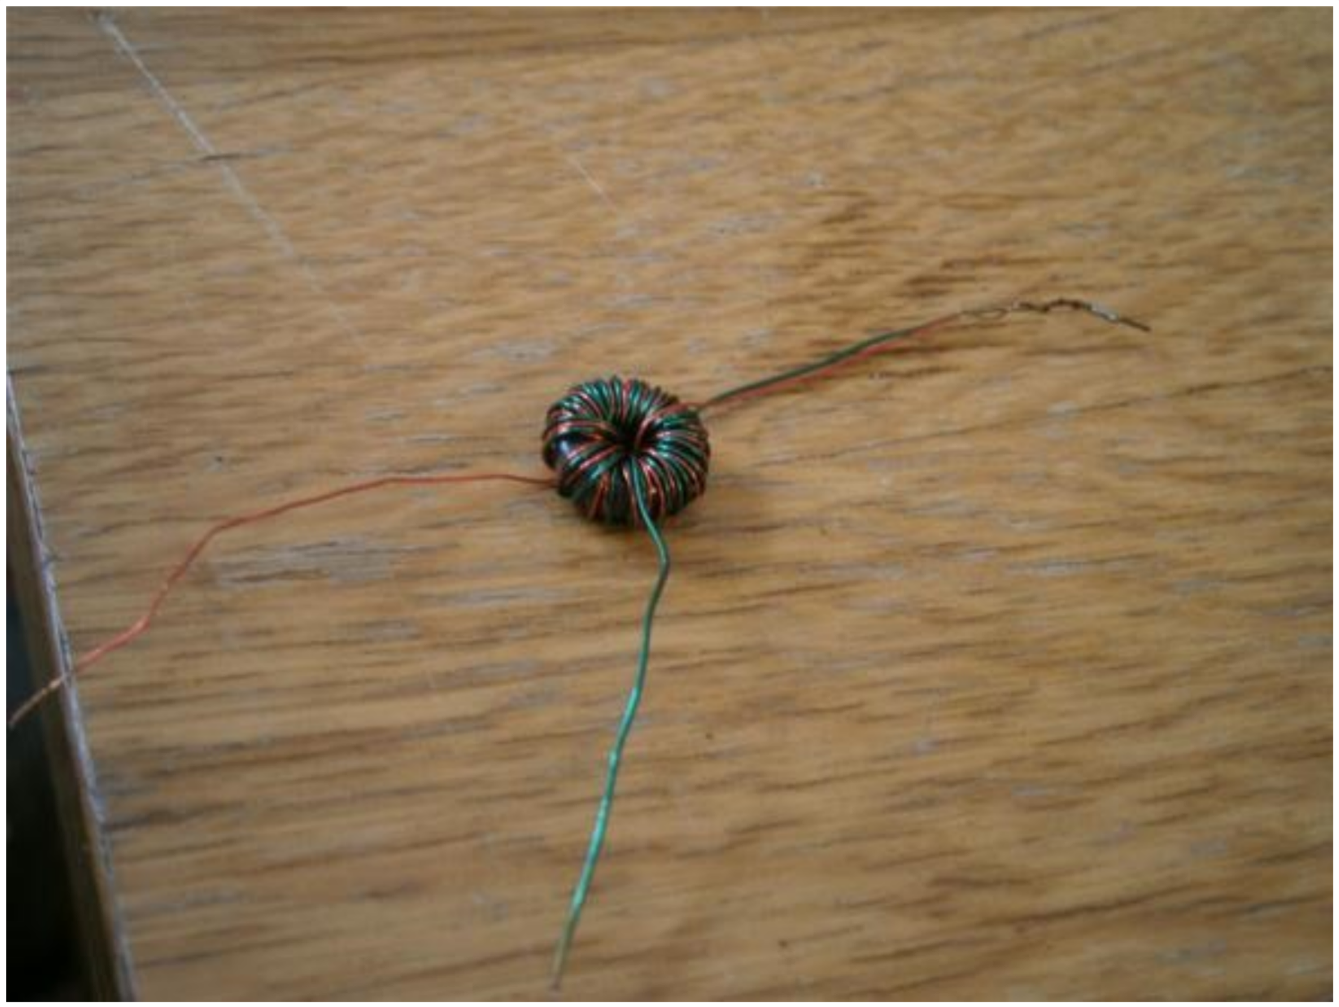
Reimagine the way home.

Shop now



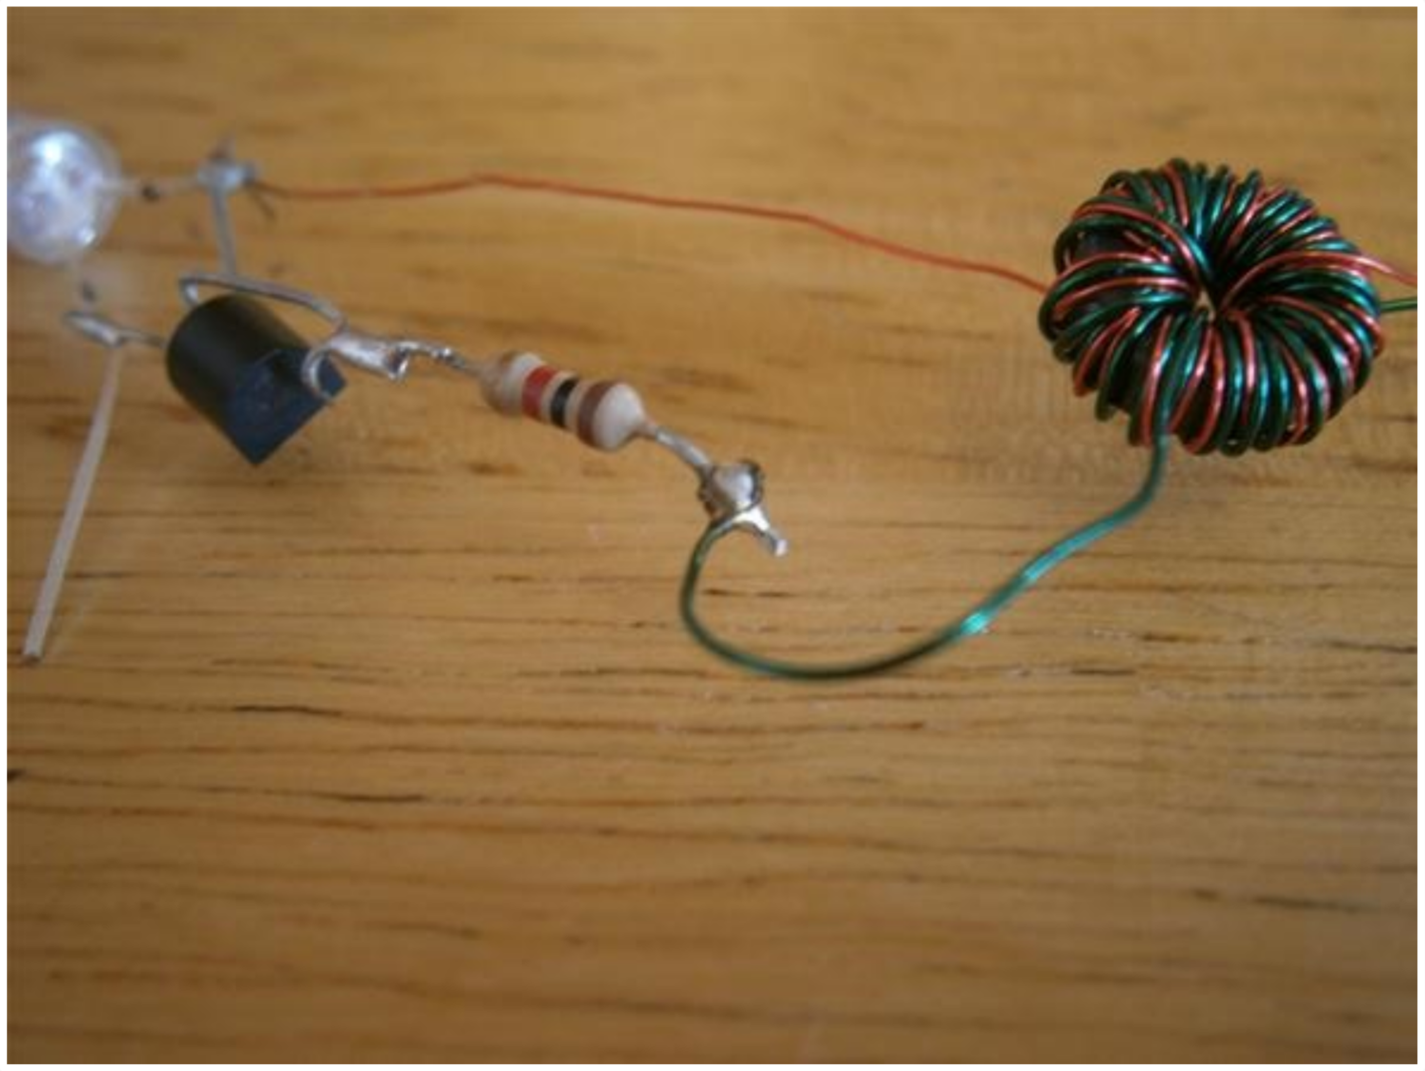
Wrap the Coil

This is where the dark magic happens. Wrap two enamel coated wires around the edge of a ferrite core. More wire will mean a stronger joule thief and a brighter LED. When you have wrapped the core, you should have two pairs of end wires. Connect one pair together as shown below on the right. Splay the other pair apart as shown below on the left.

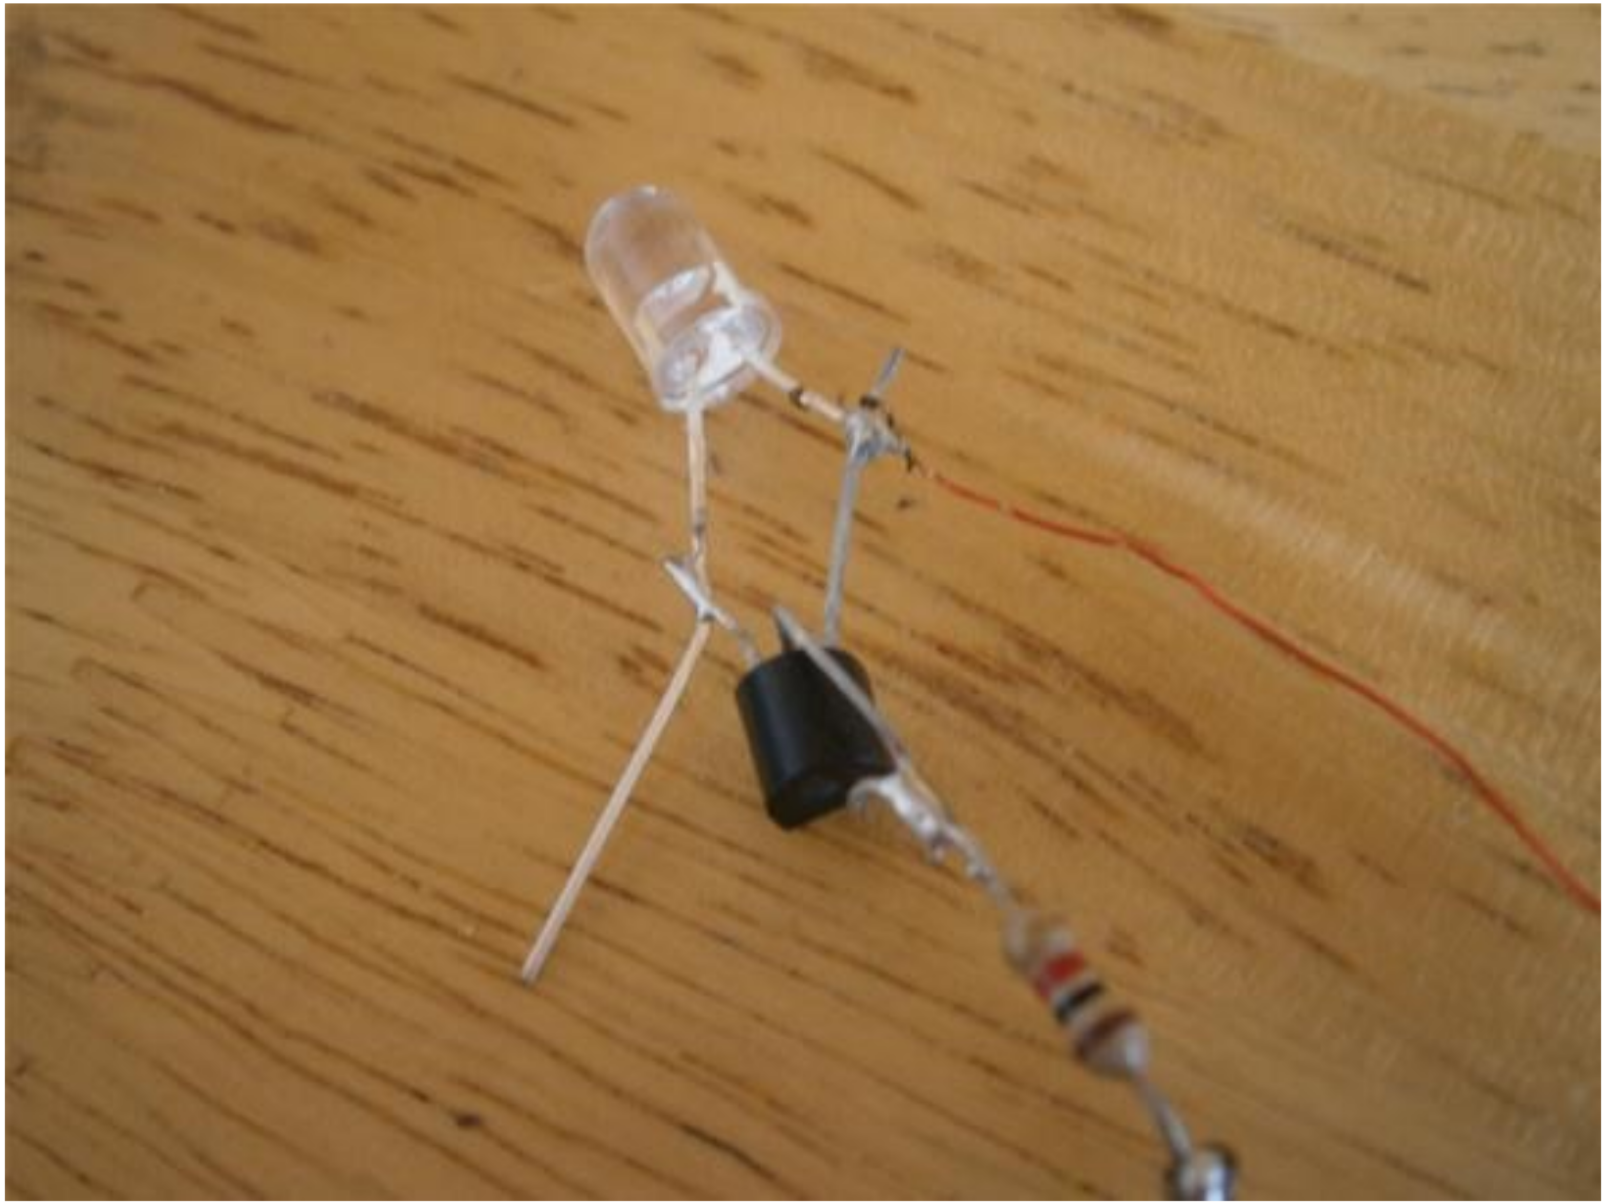


Attach Coil

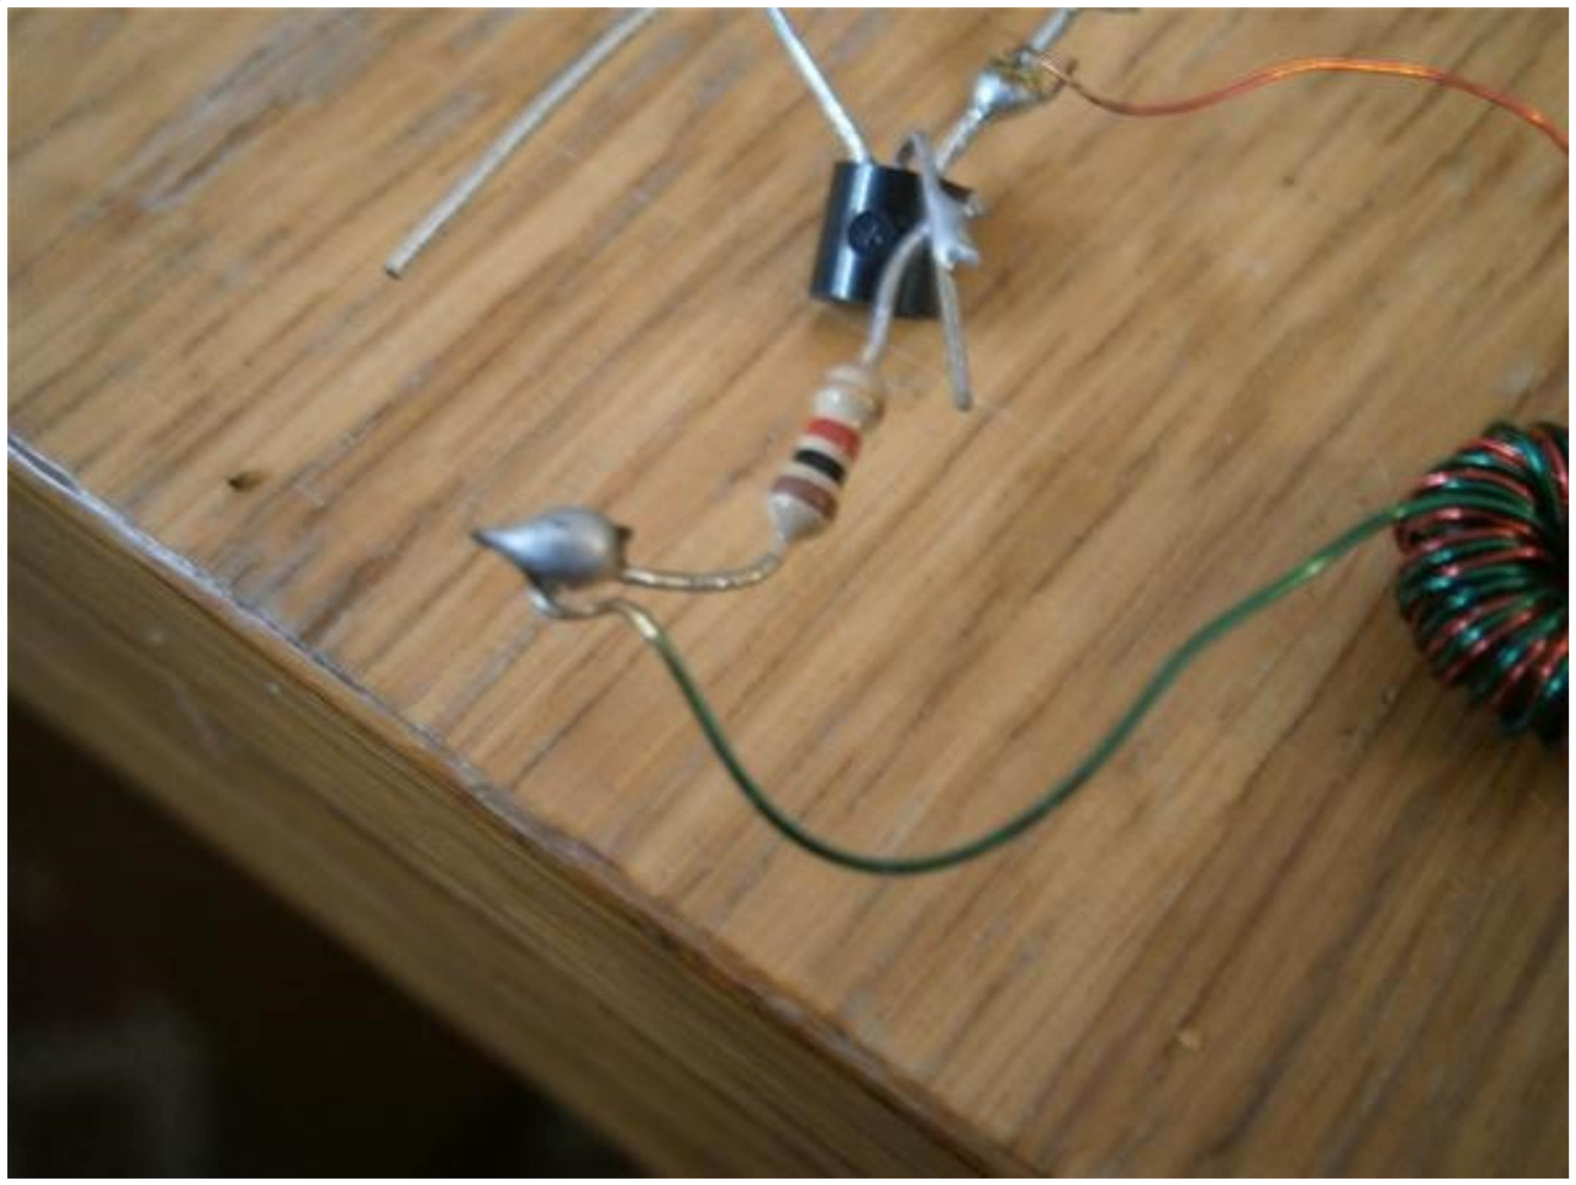
Remember to burn away the enamel on the end of the thin wire with a lighter. With the wires burned and exposed, solder one free coil wire to the 1k resistor. Solder the other free coil wire to the positive side of the LED.



Below, we have to solder a coil wire to the intersection of the transistor and the positive leg of the LED.



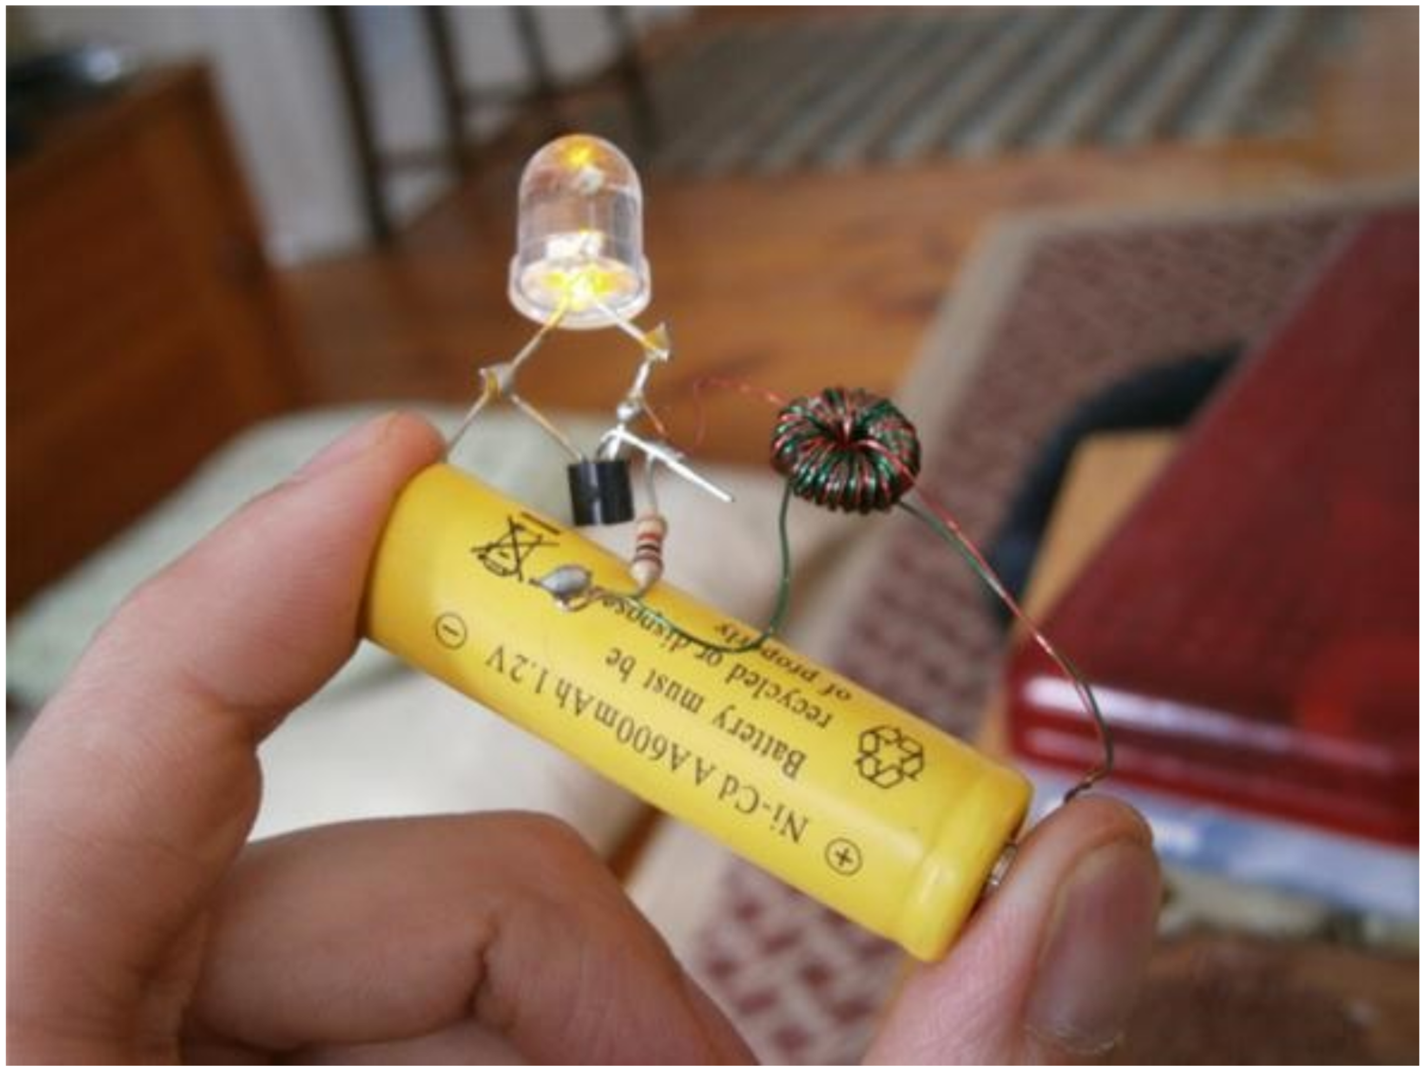
Below, notice that the end of the green enameled wire is exposed because the enamel was burned off.



Solder Cli

Solder Clip

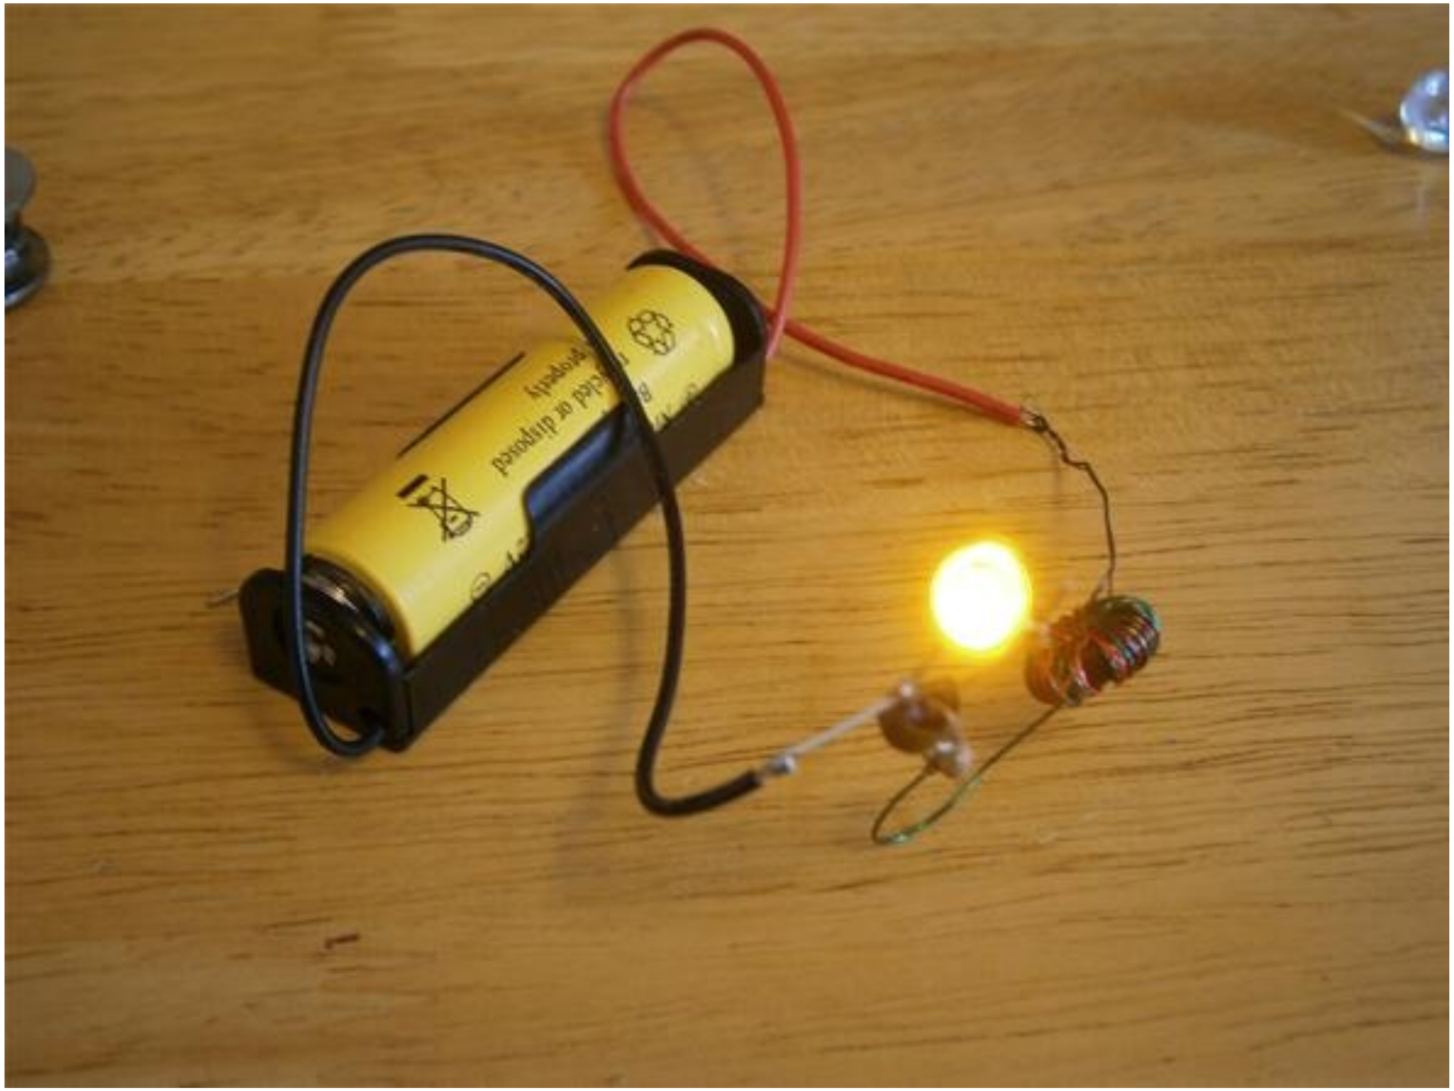
Now that the main joule thief is done, we can attach a battery clip for easy use. The joule thief will work without the battery clip, but only if you hold the wires in place with your fingers.



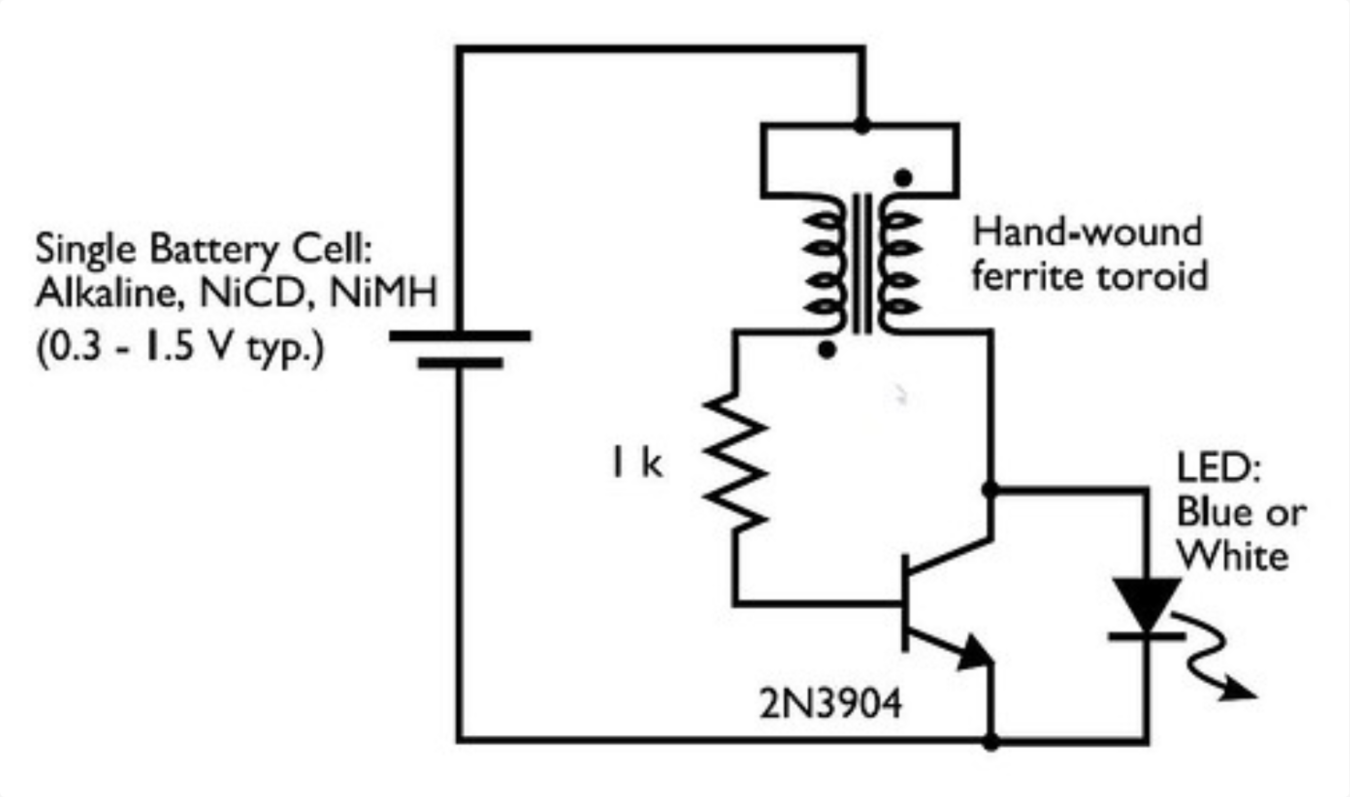
Ni-Cd AA600mAh 1.2V
Battery must be
recycled or disposed
of properly

The intertwined end of the coil connects directly to the positive battery wire. Be sure that both wires in the pair are soldered to the red wire.

The black battery wire connects to the negative end of the LED.



For those who need the schematics, this is what we just built:



Single Battery Cell:
Alkaline, NiCD, NiMH
(0.3 - 1.5 V typ.)
Hand-wound
ferrite toroid
1 k
LED:
Blue or
White
2N3904

When the current flows through the coil and around the magnet, it produce an electromagnetic field (EMF). When the coil is not powered, the field collapses and produces an EMF kick in the coil that is of a higher voltage than the source was. The last of the electricity gets stored up in the field and released in large bursts to flicker the LED. The magnetic field oscillates so quickly that the blinking LED appears solid to the naked eye.

** You can use 1N34 Germanium diode in place of OA47*

A long (at least 20 metres), high (17 metres or more) aerial and a good earth (a buried biscuit tin or a metre of copper pipe driven into damp ground) are required in order to ensure audible headphone reception. The earphones originally used with these receivers had an impedance of around 4000 ohms and were very sensitive (and heavy and uncomfortable). They are no longer available, but a crystal earpiece, which relies on the piezoelectric effect, will give acceptable results.

Low impedance "Walkman" type earphones are NOT suitable.

Component details:

Resistor- RX-4.7k, 0.25 W- only required if set is connect to audio amplifier

Capacitors- C1- 10nF disc ceramic VC1- 5p to 140p, polythene dielectric variable capacitor.

Semiconductors: D1: OA47 or 1N34- Germanium Diode

Miscellaneous: L1- Ferrite Rod, 100mm(4 inch)x9mm/10mm dia., with coil.

Crystal earpiece and jack socket to suit; plastic control knob; plastic insulated flexible cable for aerial wire, downlead and earth connection, 30 meters minimum; buried biscuit tin or 1 meter of copper pipe for earth system; 50gm reel of 26SWG enamelled copper wire, for tuning coil; card and glue for coil former; multistrand connecting wire; crocodile clips or terminals for aerial and earth lead connection; solder, etc.

Resistor - 47k - yellow-purple-black-red and brown - RR 0612 (pkt of 8)

Capacitor - 68pF - ceramic x 2 - RC 5322 (pkt of 2) and a 100 or 120 pF value as well for experiments.

Inductor - 220 uH - red-red-brown silver - LF 1538 (resistive type)

Polyvaricon tuning capacitor - 220 pF - RV 5728 - with knob and mounting screws

Diode - BAT46 - ZR 1141 (You can also use a 1N34A Germanium Diode too if you have one at home)

Ceramic Earphone - AS 3305 *

A 25 meter roll of yellow hook up wire for the Antenna wire and a 3 meter length of wire for the Ground wire.

Please note that some Jaycar parts come in multiples of 2 or more per packet. And please note the following:

PLEASE NOTE: THIS PROJECT/KIT CONTAINS SMALL PARTS THAT MAY FORM A

*A normal crystal radio earphone is OK, but if you can't get one of these, or if the one you bought goes dead (as they sometimes do,) you can use a substitute, such as the Murata PKM44EW passive transducer (see picture above) which is available from an old Telstra TF200 touchphone, (the one on the left in the diagram above,) or an equivalent, such as the ARIO transducer, from an old Telstra T1000 pushbutton phone.

The ARIO unit is soldered to the phone's pc board so you'll need to be able to unsolder the three mounting pins underneath the board, or find someone in the neighbourhood who is able.

Take the back off the TF200 (if you've obtained one of these phones,) and you'll see a black disc shaped object 2" round by 1/2' thick - with a red and black wire. Unplug the wires from the circuit board, and unscrew any retaining screws and remove the transducer. Cut the mini plug off, **carefully** strip the insulation from the ends of the wires and extend them by about 18" with 2 thin lengths of hookup wire. These pietzo devices make good earphones for crystal sets and can be housed in an old pair of ear muffs.

Miscellaneous Materials:

A Tic Tac box (smaller size)

A piece of matrix board at least 7 holes long by 8 holes across. Cut the board to fit neatly inside the Tic Tac box.

A short length of 2 differently coloured wires 60 mm in length and 2 crocodile clips with red and black plastic covers

A length of antenna wire at least 25 metres long and a 3 metre length of a different colour for the Ground wire.

A metal rod or cold water pipe for the ground stake. **Be careful which pipes you connect your Ground wire to.**

You will need a small sharp object for punching holes in the Tic Tac box.

A small pair of wire cutters for cutting and stripping wires.

If you can't hear anything in the earphone, don't panic. It might just be a simple wiring mistake, which is easily fixed. Go back over all of the steps, making sure that you have the right value components from the electronics store. Make sure that each component is in the right place on the matrix board, (don't confuse the L1 inductor with the R1 resistor - they look a lot like each other!) and that no component wires have come undone from the twisted joins you have just made. I'll be writing up a troubleshooting step soon, so if you run into any problems, post your questions in the 'comments' section down at the bottom of the page, and I'll try and answer them as soon as possible.

Make sure that your antenna and ground wires aren't snagged on anything metal or anything **dangerous!**

If you have ANY doubts about the electrical safety of your antenna or ground wires, then consult a licensed electrical trades person, who will be able to advise you on electrical safety principles and procedures!

Always remember that electrical safety is your responsibility! If you don't think it is safe to proceed, then don't!

You will need at least 10 to 15 metres of antenna wire, strung between 2 insulating points (not connected to anything metallic, or that gets wet,) at least 2 to 3 metres in height - anything less than this minimum arrangement may mean that you cannot receive any signals at all

Step 7: Adding the Polyvaricon Tuning Capacitor

The Nic Nac Tic Tac Crystal Radio

By Austin Hellier © 1992 - 2014

[illegible] around for over 100 years and [illegible] in many different shapes, si[illegible] [illegible] nitely better than others, but w[illegible] orrectly and connected to [illegible] system, this simple little AM radio receiver should pull in at leas[illegible] [illegible] or you to listen in to. In diagram [illegible] you can [illegible] the basic layout [illegible] [illegible] lled crystal sets, as the original designs used [illegible] material c[illegible] or p[illegible] [illegible] element, which picks out the [illegible] o wave. [illegible] tals have been replace[illegible] with a modern component call[illegible] o use on[illegible] as we put this kit together.

How It Works

Signals from your local AM radio stations are traveling [illegible] the sp[illegible] and they pass through just about everything . These sig[illegible] and in[illegible] small signal current that flows down into the radio's tun[illegible] the g[illegible] to Earth. The coil, L1 and fixed capacitor, C1, form the 't[illegible] in c[illegible] with the antenna/ground wire system, which enables the [illegible] tion's and reject the rest. This may seem like a limitation on th[illegible] you [illegible] ot thi[illegible] ceiver going, you can add one or two more parts in order [illegible] on th[illegible] across part or all of the AM radio band, for just a couple of dollars more. All you [illegible] ve to several parts of differing values around, (included in your [illegible]) until you receive [illegible] aso[illegible] local AM radio station! Experimenting is half of the fun with these circuits.

The frequency selected by this process is comprised of two [illegible] - the 'carrier wa[illegible] wh[illegible] dio station's fixed frequency (its 'spot' on the dial of a trans[illegible] the 'pro[illegible] which is the voice, music, secret sound, which originates inside the radio station's studi[illegible] signal that we want, and the next component, the diode, D1, enables the sound or aud[illegible] be split away from the carrier wave. This is called the 'detector' because it detects the [illegible] contained inside the carrier wave.

[illegible] the sound waves that we want a[illegible] produ[illegible] [illegible] EP, as the diaphragm inside the earphone[illegible] [illegible] with th[illegible] ming from the diode, re[illegible] [illegible] hrough the [illegible] ground, a[illegible] thus comp[illegible] ond 'detect[illegible] circuit. Resistor, R1 pro[illegible] for pietzo[illegible] earphones, [illegible] these devices path to [illegible] them to work properly and n[illegible] signal[illegible]

Co[illegible] ntificatio[illegible]

[illegible] made of ceramic [illegible] r blue [illegible] ceramic material. Th[illegible] two [illegible] metal [illegible] and allow RF (Radio Fre[illegible] electr[illegible] easured in [illegible] s (pF). Th[illegible] through. Sma[illegible] ce, with coloure[illegible] icate its larger cylind[illegible] called [illegible] (uH). The diode [illegible] mall blue or red coloured body - a signal [illegible] AT 40) and is made of a sp[illegible] throu[illegible] all[illegible] signals to pass through to the e[illegible] but prevents the carrier wave fro[illegible] and is [illegible] [illegible] manium, but they are harder to get no[illegible] - this BAT46 model is called a Schottky [illegible] radio detector diode, even though it is made of silicon.

[illegible] resistor, which is measured in ohms. This res[illegible] a 150[illegible] one, [illegible] to the ground side of the ci[illegible]

3:18 Find "motivated" sellers (especially people on the tax delinquent list for 2+ years)
5:04 Skip trace the list (to get their phone numbers & contact info)
9:30 Call each person on the list, from a Google Voice number using software like MojoDialer
11:10 Ask each person if they want to sell their property, following a cold-call script
13:09 If they say yes, ask them what they think the property's worth
13:24 Ask them how much repair/reno costs will be
13:46 Ask them how much they owe on the property
14:05 Ask them when they need their property to be sold
14:20 Ask them "if I can give you an all-cash offer, close quickly and pay all closing costs, how much do you want for your property?"
14:43 No matter what they respond, ask them "is that the best you can do?"
15:00 Set up a time to go and meet them at their property, collect their best phone number & email, add all the info to your database so you can follow up with them
15:40 Set up appointments with as many people as possible to gain experience
16:42 If the numbers make sense, put the property under contract (with a Purchase & Sale Agreement)
16:55 Post the deal everywhere ("Contract for Assignment"); you are selling the contract on the property, NOT the property itself
17:20 Try to find a buyer for the contract in three to five days; if it's not sold by then the "deal" probably isn't that much of a deal. Ask a realtor to run more accurate comps to see what's wrong.
18:18 Sell the contract to a buyer (with an Assignment Agreement) at a markup (your assignment fee)
18:22 Send the Purchase & Sale Agreement and the Assignment Agreement to a title company, to get the deal closed

DETERMINE YOUR MAXIMUM ALLOWABLE OFFER

Once you've determined the Rehabber's Maximum Purchase Price you will deduct your wholesaler assignment fee/profit to determine the Maximum Allowable Offer you can offer for the property.

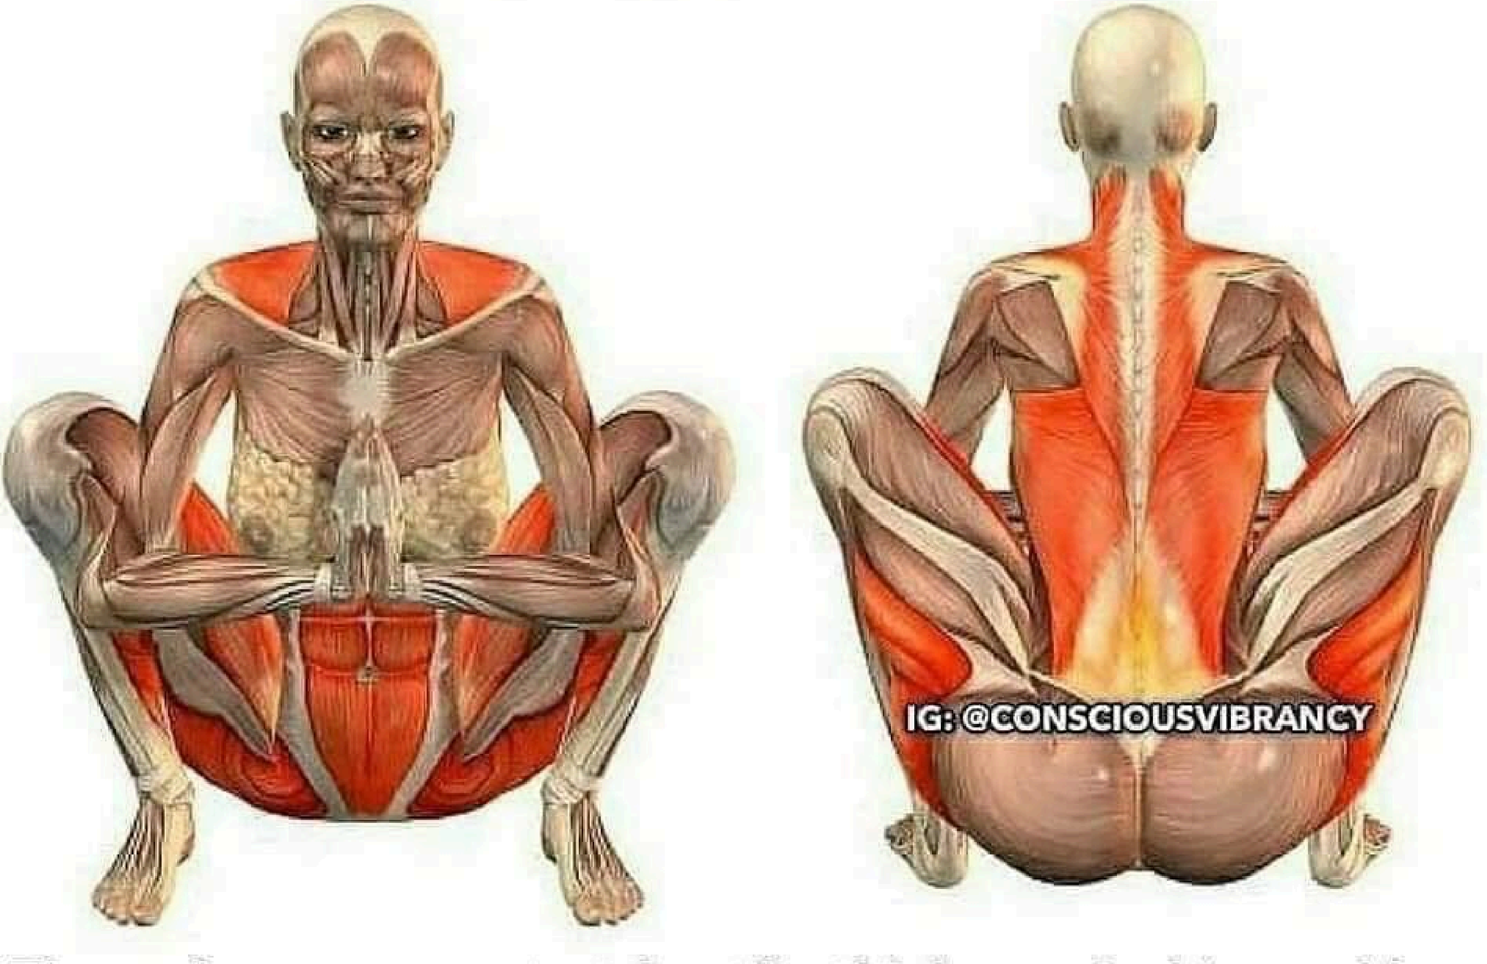
DID YOU KNOW?

The Malasana Pose Has Many Benefits



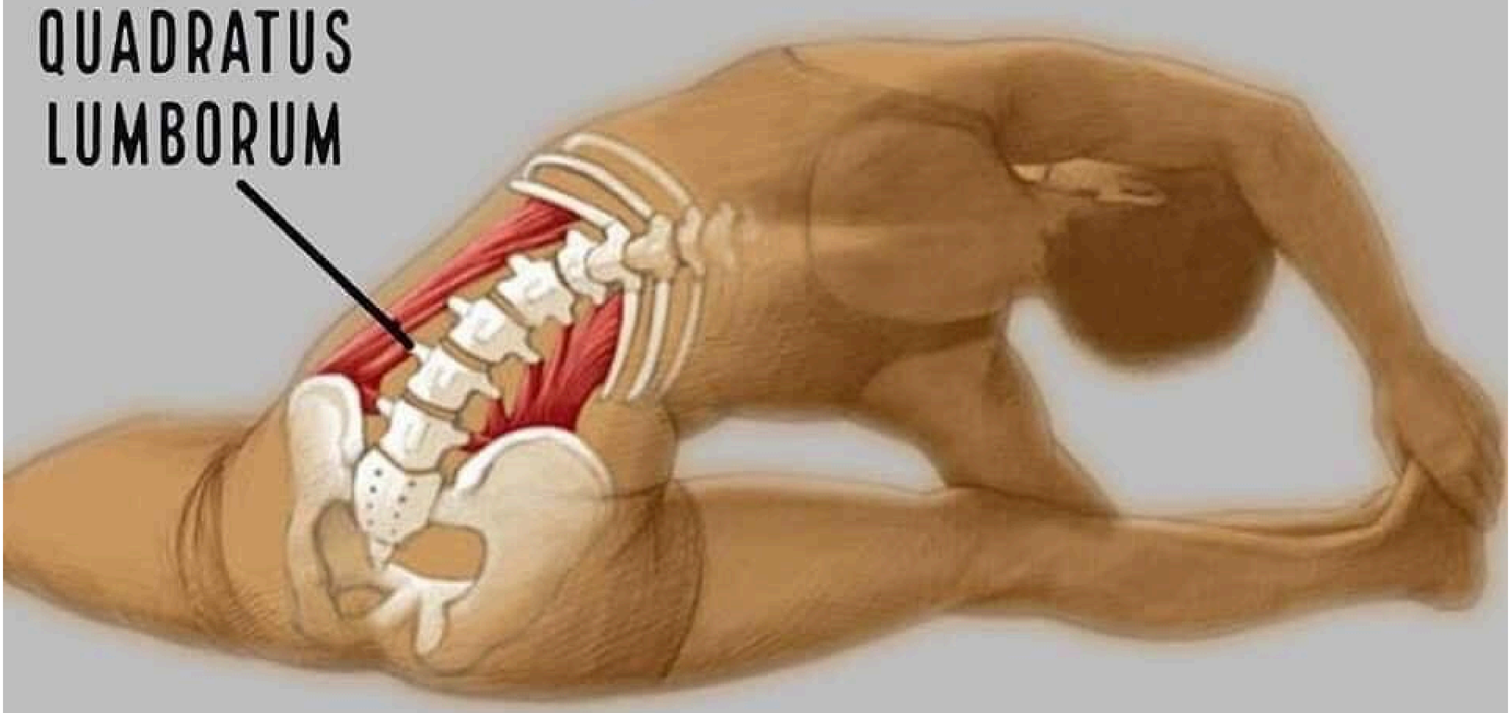
The malasana pose stretches the thighs, groin, hips, ankles, and torso. It tones the abdominal muscles and improves the function of the colon to help with elimination. This pose also increases circulation and blood flow in the pelvis, which can help regulate sexual energy.

SOURCE: YOGAOUTLET

DID YOU KNOW?

WHEN YOU DO THIS STRETCH DAILY...

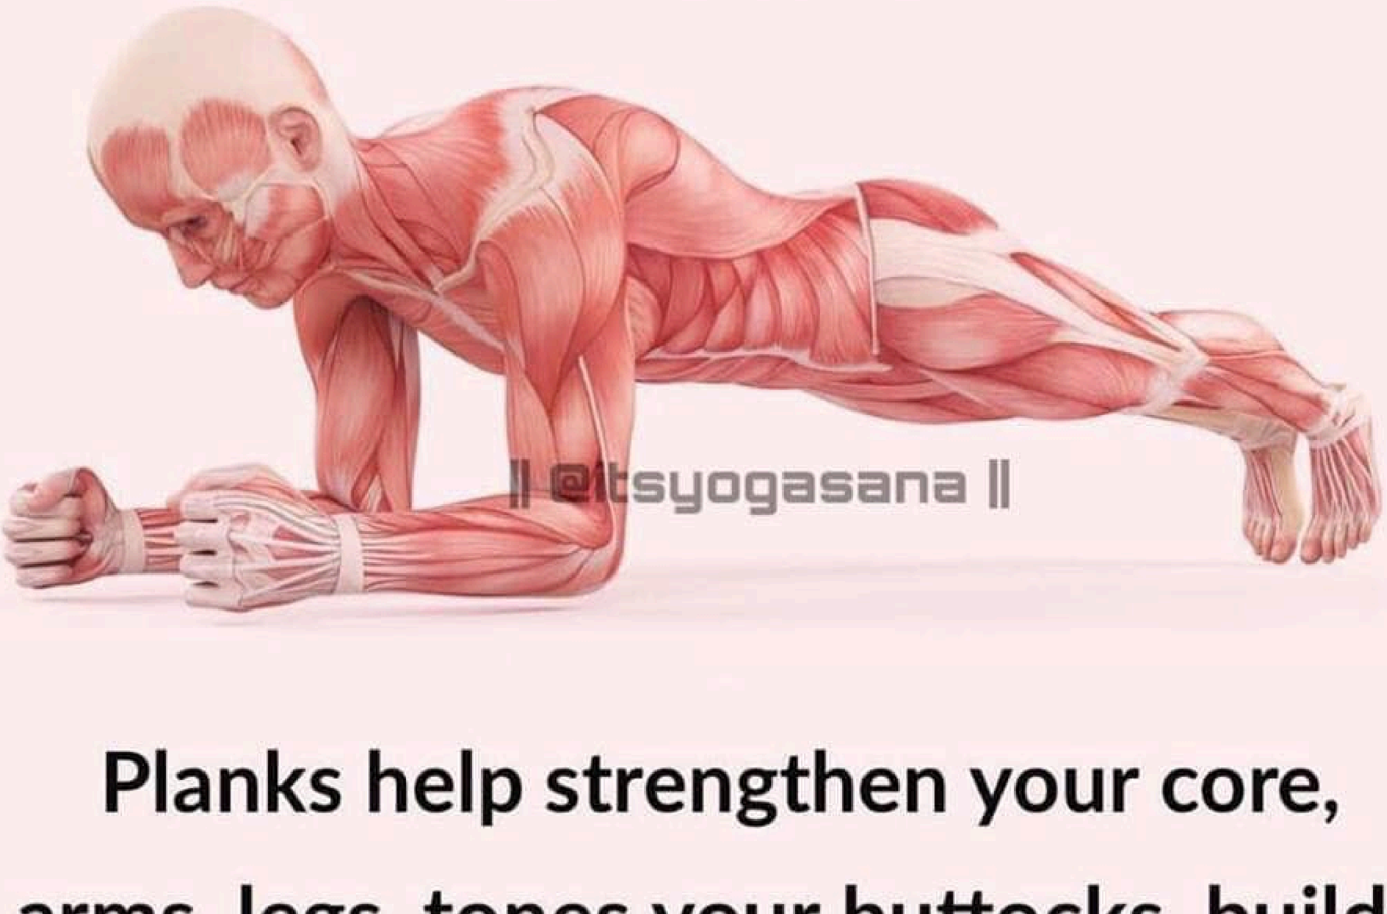
Holistic Ali



THIS IS THE AREA THAT CAUSES STIFFNESS AND LOWER BACK PAIN FROM LACK OF STRETCHING. THIS AREA MUST BE STRETCHED DAILY, ESPECIALLY IF YOU SIT ALL DAY.

DID YOU KNOW?

PLANKING FOR A FEW MINUTES PER DAY...



|| @itsyogasana ||

Planks help strengthen your core, arms, legs, tones your buttocks, builds abs & improves your mental focus

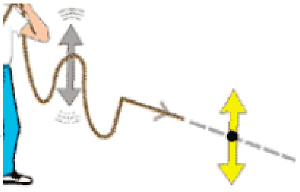
Heat emerges at transmitter/receiver
Heat emerges at transmitter/receiver

In the endothermic mode, tremendous heat is received back in the transmitters. Soviets further retransmit the heat via interferometers to a distant "exhaust" point. Bennett Island was used for such an exhaust point for decades, and our observation platforms saw a great many 150 miles-long jets of exhaust effects in narrow beams at shallow angles.

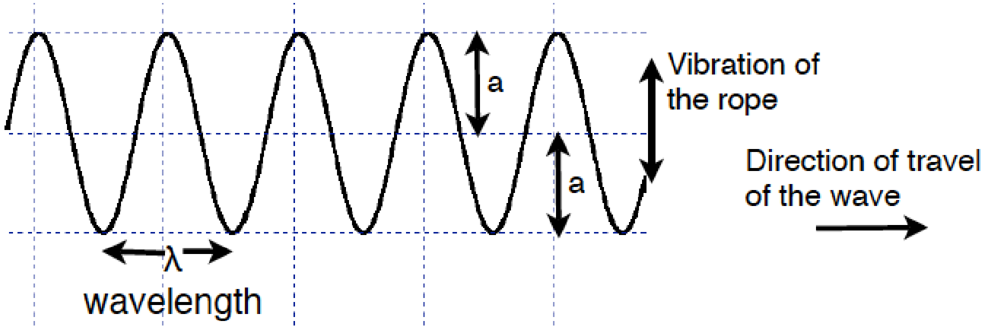
Measuring Longitudinal and Transverse waves

The Fizzics Organisation

Transverse waves
A shaking rope is a good example. The wave moves along the rope but the bits of rope go up and down - across the direction of the wave. “Trans” means across, think of “transatlantic” or “transfer”.



A water wave is another example of a transverse wave.



a is the amplitude of the wave measured from the maximum height to the middle. Think of a water wave, it is the distance from either the crest or the trough to where the water would be if it were calm.

λ is the wavelength. That is the distance from one point on a wave to the same point on the next wave - for example from crest to crest or trough to trough.
f is the frequency of the wave, that is the number of waves which are produced every second (or the number passing every second). This number is given the unit “hertz”. One hertz is one wave per second.

Most of the examples of waves we have to deal with are transverse waves. All the waves in the electromagnet spectrum are transverse waves.

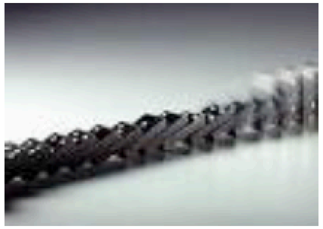
There is a connection between the frequency and wavelength of a wave. If the frequency is increased - if there are far more waves, then they are closer together; in other words the wavelength is less.
The speed is equal to the frequency multiplied by the

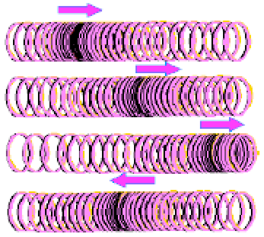
$$V = f \times \lambda$$

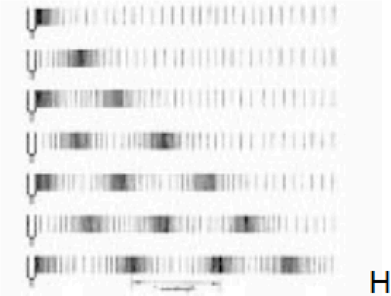
m/s hertz metres

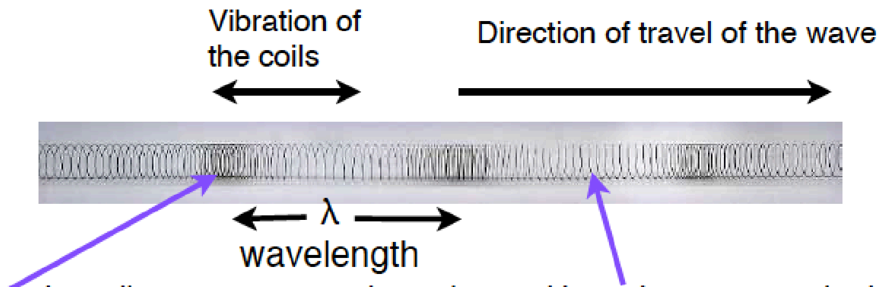
A longitudinal wave is a “pushing” wave. A line of dominos falling is an example.

If one end of a slinky is pushed and pulled then each coil pushes and pulls the next. The coils oscillate along in the same direction that the wave is traveling.









Here the coils are compressed together and here they are stretched out.

one leg is longer
than the other
LED (Light Emitting Diode)
(C - Collector, B - Base, E - Emitter)

Transistor - The legs of the transistor can be determined by noticing that there's a flat side to the transistor case. See the diagram above. A large number of transistors have been reported to work: 2N4401, NET123AP, BC547B, 2SC2500, BC337, PN2222, to name just a few.

LED - One leg of the LED is longer than the other leg. Use this to determine which one goes where. See the diagram above.

Resistor - The diagram says use a 1 kilo ohm resistor but I've used an 820 ohm one just fine. I've also seen a 2 kilo ohm one in use. Use whatever works for you. You can also use a potentiometer (a variable resistor) so that you can easily adjust it to select the resistance that gives the best light.

Toroid ferrite core - Some people have gotten these by opening up compact fluorescent lightbulbs (CFLs). I took mine out of some device whose original function I don't know. To get it working, my first one had just 13 turns for each wire and I used a 30 gauge wire and a 26 gauge wire. The wire must be insulated. A variety of number of turns will work. This is something you can play with. Look at the diagram carefully to determine where the wires connect to.

Diagram 1. MK484 Radio Receiver for the AM Band

Build This Modern AM Radio Receiver For Just $12.00!

This adaption of the famous ZN414 (now MK484 plastic pack) AM radio receiver, was inspired by the fact that I live fairly close to my three local AM stations (2WL, 2WN and the ethnic broadcaster 2RPH) and would normally receive overloaded signals with a standard TRF design based on this IC. With the minor modifications made to the basic design as shown, and with the aid of the inductive coupling arrangement, i can pick up all three stations with clarity and volume, and with hardly any (and I mean ANY) interference from each other, and no oscillations!

Make sure that you wire the MK484 (IC1) up correctly - the pinouts shown above are seen from the top of the device. Wind L2 so that it fits snugly on the end of the rod, right next to the end of L1 's winding. The average 9 volt battery gives much better volume and selectivity, and should last for some months of constant use - if you've got a few spare $, try a new Eveready Lithium or the new Kodak Alkaline!

MK484 ICs are available from **http://www.dse.com.au/** (cat# Z6525 for $2.36AUD).

Construction

You can make this circuit up quickly on your SK-10 panel, or use something like the Dick Smith "Funway

Coil former
Balun core and modified stick

How It Works

Radio signals are travelling through the atmosphere all the time. This simple radio receiver has been designed to capture them, and turn them into sound waves, so that you can hear what's going on. The Aerial and Earth wires form a return signal path from the AM transmitter, for these signals, and they are then fed into the coil and capacitor. This arrangement is known as a 'tank' circuit, because it stores radio energy, much in the same way your family car's tank stores petrol. The combination of a certain sized capacitor (68pF) and the amount of turns on the coil (around 120 turns) determines the frequency you will receive at. The Diode changes the signal from a radio one, to an audio one, and the Crystal Earphone changes the audio signal into sound waves that you can hear. the resistor adds stability by helping to prevent the Earphone from occasional 'dropout'.

Building The Radio

You'll need all the components listed below and a Tic Tac lolly box. Start by mounting the earphone jack into the lid of the box and then solder up each of the components into a tidy version of the 'rat's nest' construction method. Make sure you use a crocodile clip as a heat sink for the diode when soldering - they're pretty sensitive devices to heat. Then take the coil and remove the ferrite rod from inside it. Take the ferrite balun core and place one end of the plastic stick (obtained by cutting off both ends of a cotton bud) and glue it inside the hole, with its end level with the end of the balun core.

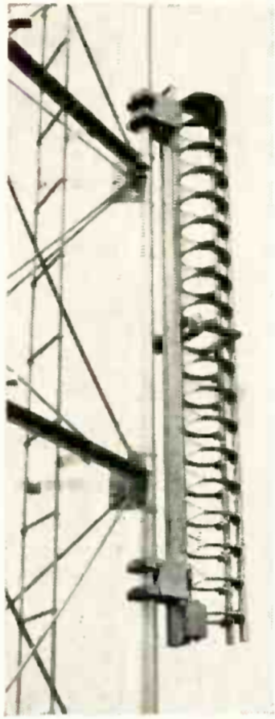
AMCI BROADCAST EQUIPMENT for VHF and UHF-TV and FM



VHF-TV
Transmitting Antennas

VHF-TV TRANSMITTING ANTENNAS

Mast or tower-corner mounted
DIRECTIONAL OR OMNIDIRECTIONAL
for Channels 5 to 13

Omnidirectional VHF-TV antennas with power gains up to 20. Directional VHF-TV antennas with power gains up to 36.

UHF-TV TRANSMITTING ANTENNAS

Mast, tower-corner, or truss-mounted
DIRECTIONAL OR OMNIDIRECTIONAL
for Channels 14 to 83

Omnidirectional UHF-TV antennas with power gains up to 50. Directional UHF-TV antennas with power gains up to 80.

FM TRANSMITTING ANTENNAS

Mast or tower-corner mounted
DIRECTIONAL OR OMNIDIRECTIONAL

For single or multi-station transmission.

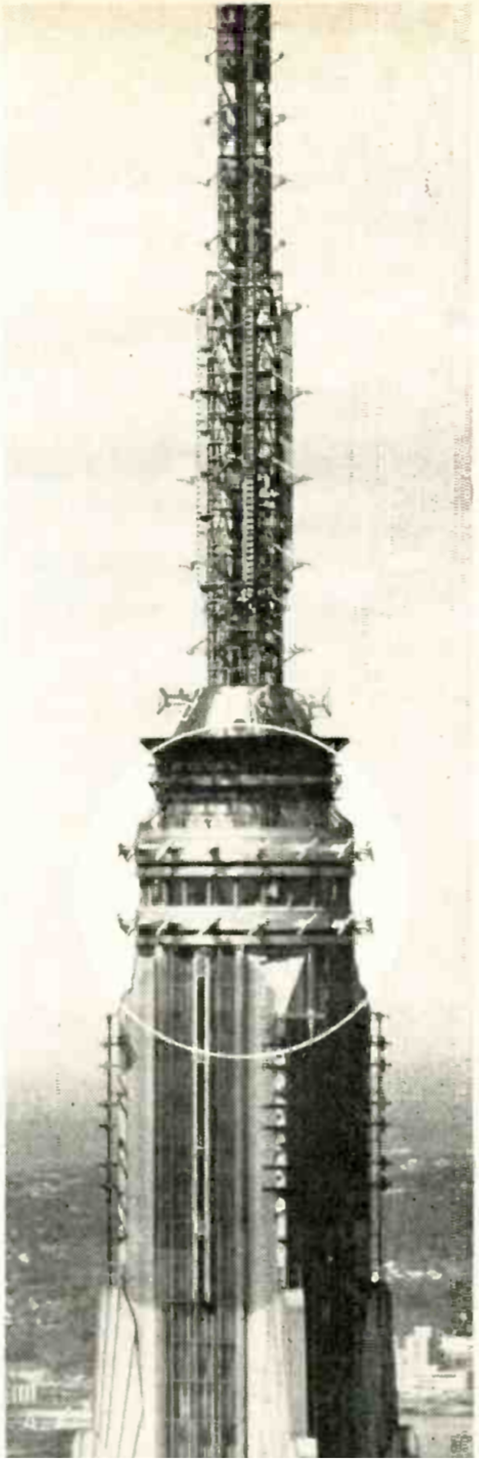
UHF-TV
Transmitting Antennas

SPECIAL PURPOSE ANTENNAS

The Empire State Building Master FM Antenna; two rows of dipoles around the 102nd floor observation level, the diplexers within the tower, and the transmission line, designed, built, and installed in 1965, permit up to 17 FM stations to broadcast simultaneously from the same antenna.

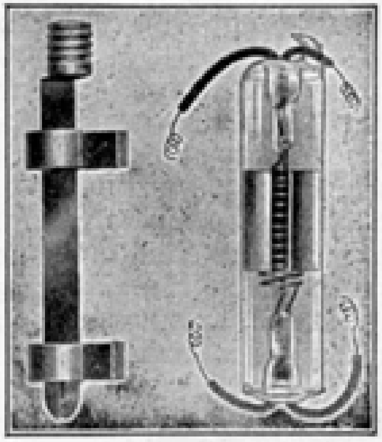
DIPLEXING FILTERS

Temperature compensated. Aural-to-visual and visual-to-aural rejection over 30 db. For use with transmitters up to 50 kw.



THE DE FOREST AUDION

"There is only *one* Audion—the De Forest"



THE GENUINE DE FOREST TUBULAR AUDION

Is sold separately to any amateur who prefers to build his own Audion Detector **Price $5.50**

Adapter 40 cents extra.

Get the Bulletin (X16)

MOST SENSITIVE

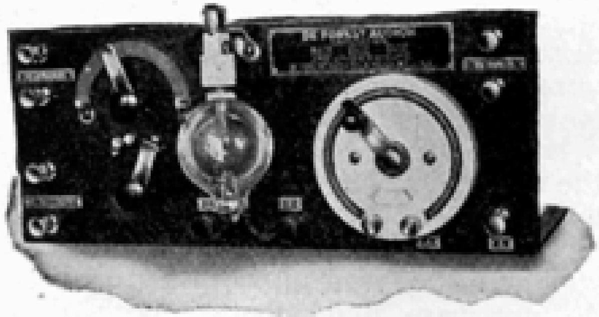
The Bulletin of the U. S. Bureau of Standards states that the De Forest Audion is fully 50 per cent. more sensitive than any other known form of detector (Vol. 6, No. 4, page 540).

MOST RELIABLE

It is not affected by mechanical vibration nor burned out by static or the transmitting spark. It never fails at the critical moment.

The detector is the heart of the receiving set. Why waste valuable time on an insensitive, unreliable detector?

The genuine De Forest Audion is now within the means of every operator.



THE TYPE RJ9 DE FOREST AUDION DETECTOR

Incorporates the Audion Bulb and the genuine De Forest patented circuits with the most approved accessories needed to form a complete detector.

The most popular Audion Detector ever offered. **Price $14.00**

Get the Bulletin (M16)

WARNING—You are entitled to the genuine Audion, guaranteed by the owners of the Audion patents, when making an investment of this kind. Any evacuated detector having a filament, a grid and a plate, as well as other types, are covered by our patents, and several irresponsible infringers are being prosecuted. To be safe and get full value for your money, insist on the genuine De Forest Audion.

US Amateur Radio Bands

US AMATEUR POWER LIMITS

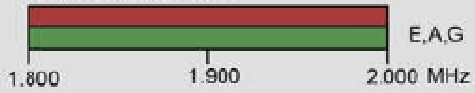
FCC 97.313 An amateur station must use the minimum transmitter power necessary to carry out the desired communications. (b) No station may transmit with a transmitter power exceeding 1.5 kW PEP.

Effective Date
March 5, 2012

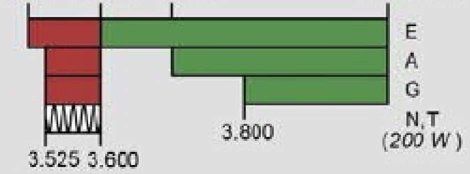
Published by:
ARRL The national association for AMATEUR RADIO ®
www.arrl.org
225 Main Street, Newington, CT USA 06111-1494

160 Meters (1.8 MHz)

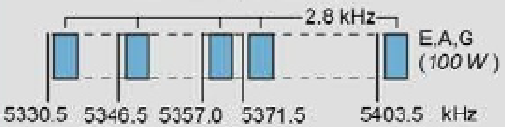
Avoid interference to radiolocation operations from 1.900 to 2.000 MHz



80 Meters (3.5 MHz)

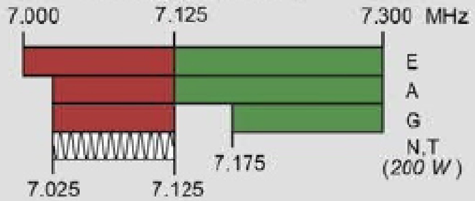


60 Meters (5.3 MHz)



General, Advanced, and Amateur Extra licensees may operate on these five channels on a secondary basis with a maximum effective radiated output of 100 W PEP. Permitted operating modes include upper sideband voice (USB), CW, RTTY, PSK31 and other digital modes such as PACTOR III as defined by the FCC Report and Order of November 18, 2011. USB is limited to 2.8 kHz centered on 5332, 5348, 5358.5, 5373 and 5405 kHz. CW and digital emissions must be centered 1.5 kHz above the channel frequencies indicated above. Only one signal at a time is permitted on any channel.

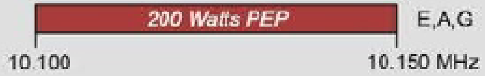
40 Meters (7 MHz)



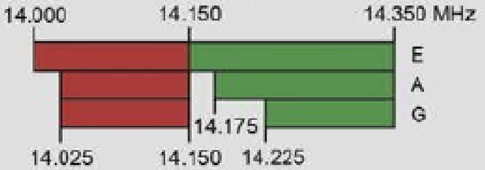
Phone and Image modes are permitted between 7.075 and 7.100 MHz for FCC licensed stations in ITU Regions 1 and 3 and by FCC licensed stations in ITU Region 2 West of 130 degrees West longitude or South of 20 degrees North latitude. See Sections 97.305(c) and 97.307(f)(11). Novice and Technician licensees outside ITU Region 2 may use CW only between 7.025 and 7.075 MHz and between 7.100 and 7.125 MHz. 7.200 to 7.300 MHz is not available outside ITU Region 2. See Section 97.301(e). These exemptions do not apply to stations in the continental US.

30 Meters (10.1 MHz)

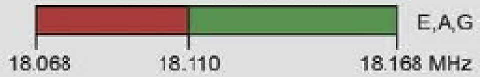
Avoid interference to fixed services outside the US.



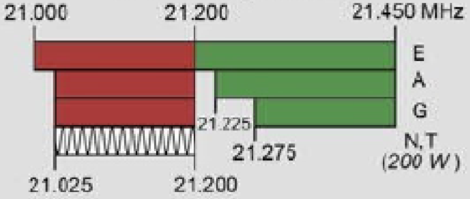
20 Meters (14 MHz)



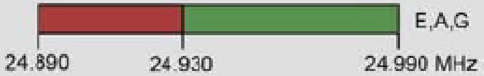
17 Meters (18 MHz)



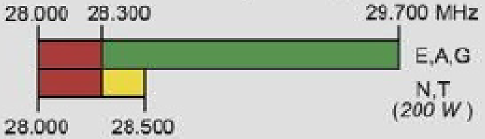
15 Meters (21 MHz)



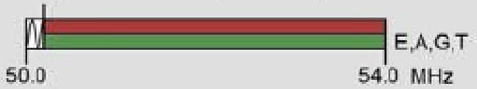
12 Meters (24 MHz)



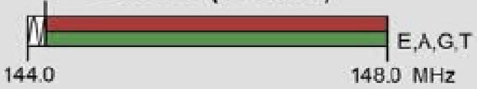
10 Meters (28 MHz)



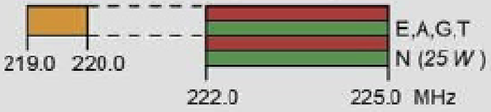
6 Meters (50 MHz)



2 Meters (144 MHz)

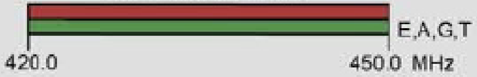


1.25 Meters (222 MHz)

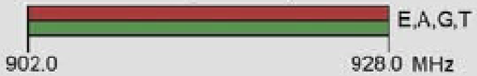


*Geographical and power restrictions may apply to all bands above 420 MHz. See *The ARRL Operating Manual* for information about your area.

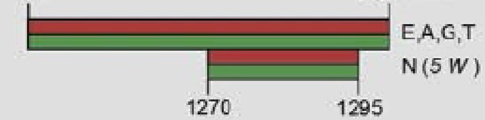
70 cm (420 MHz)*



33 cm (902 MHz)*



23 cm (1240 MHz)*



All licensees except Novices are authorized all modes on the following frequencies:

2300-2310 MHz
2390-2450 MHz
3300-3500 MHz
5650-5925 MHz
10.0-10.5 GHz *
24.0-24.25 GHz
47.0-47.2 GHz
76.0-81.0 GHz
122.25-123.0 GHz
134-141 GHz
241-250 GHz
All above 275 GHz

* No pulse emissions

KEY

Note:

CW operation is permitted throughout all amateur bands.

MCW is authorized above 50.1 MHz, except for 144.0-144.1 and 219-220 MHz.

Test transmissions are authorized above 51 MHz, except for 219-220 MHz

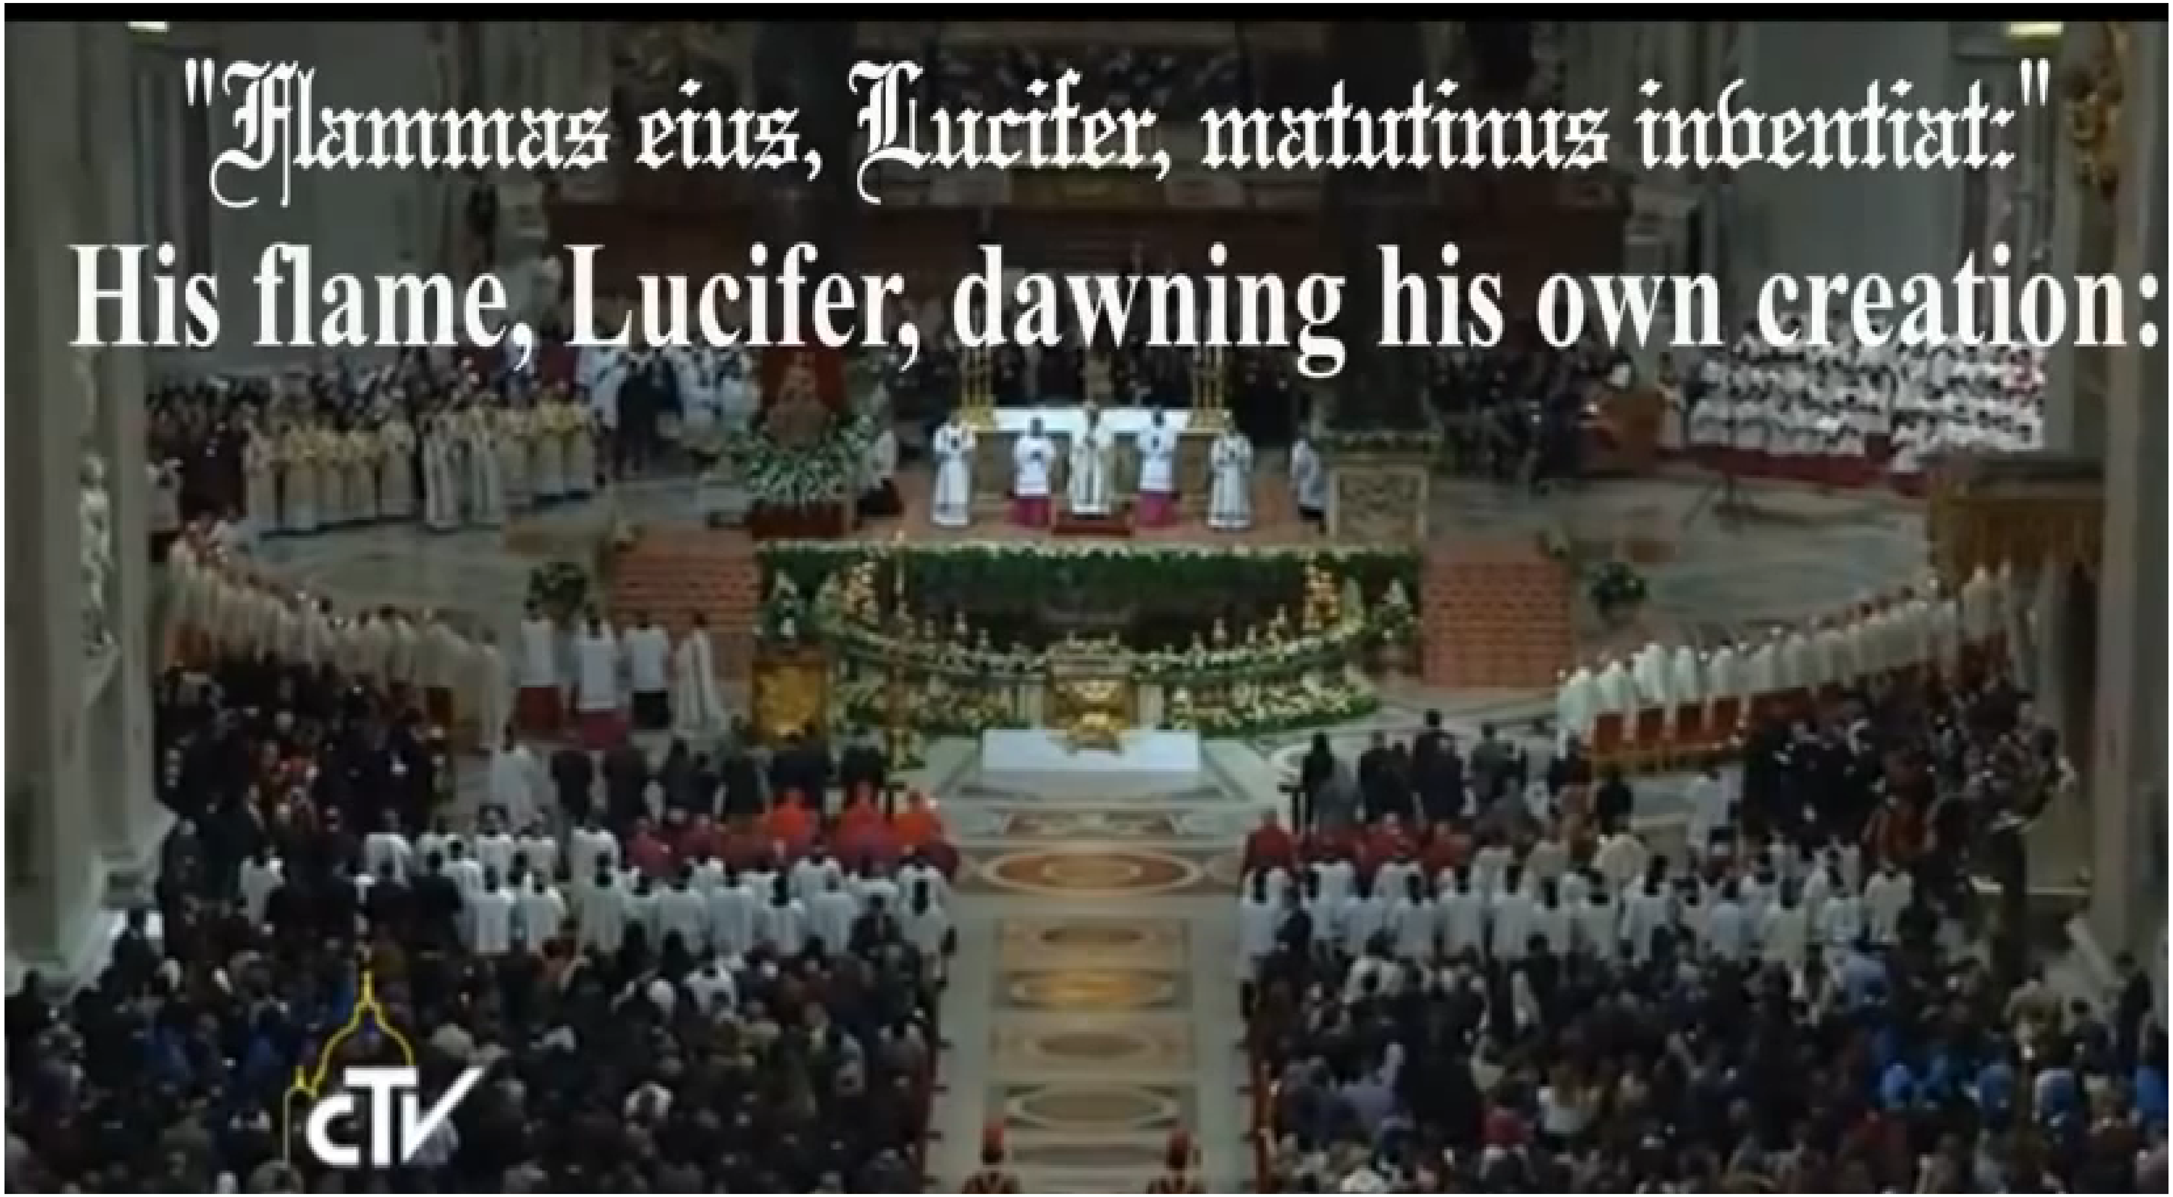
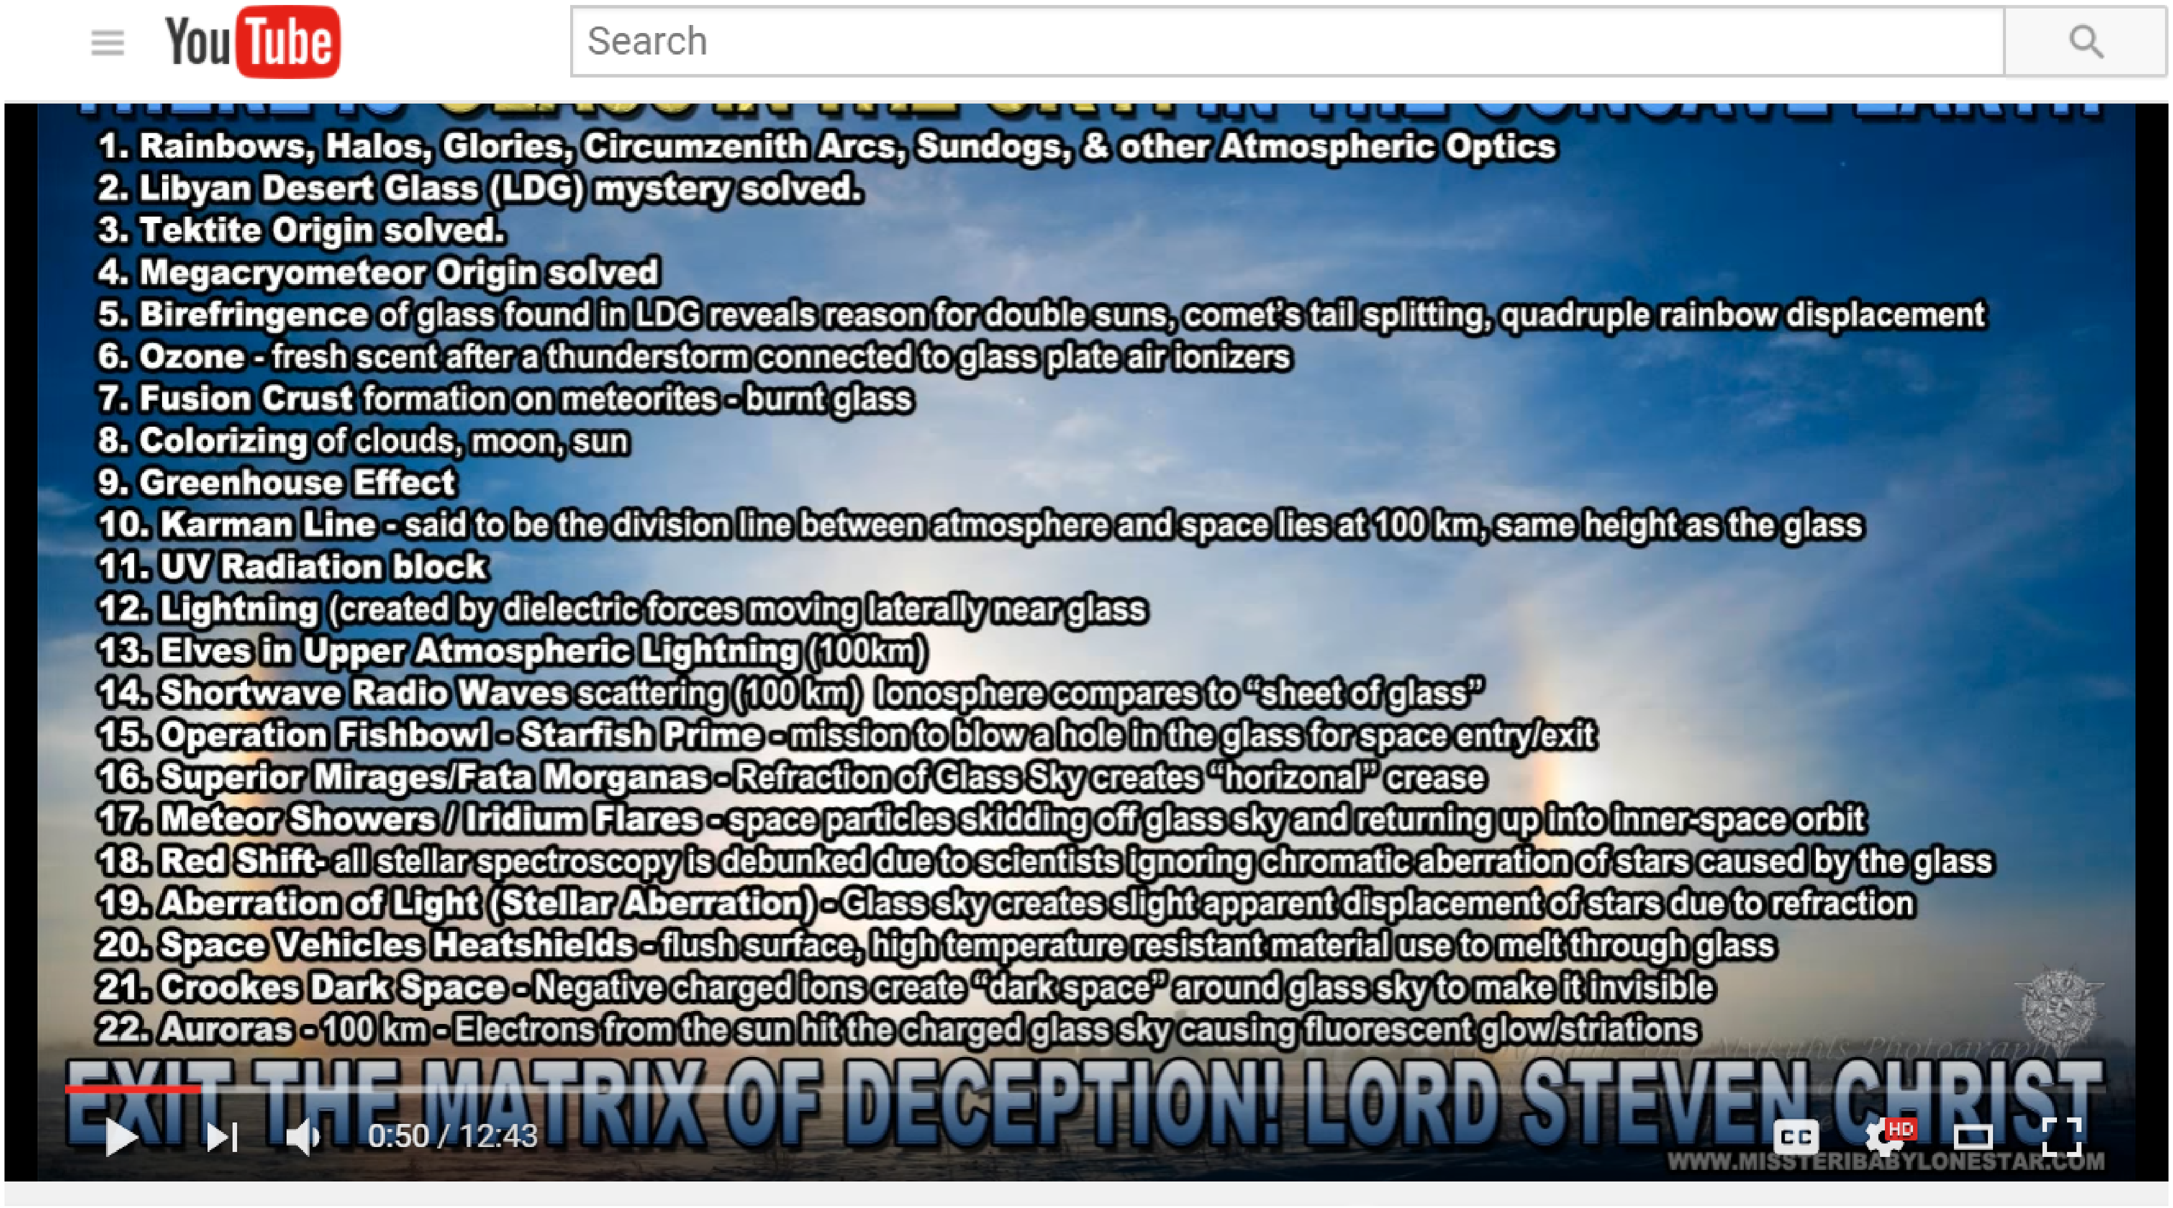
THE GREATEST OPERATIVE MASON MEETS THE GREATEST SPECTULATIVE MASON is Ben Bey Emmanuel Mu Ali, historically known as Benjamin Banneker really Prince Hall? Benjamin Banneker (November 9, 1731 – October 9, 1806) was a free African American astronomer, mathematician, surveyor, almanac author and farmer. Prince Hall (c.1735 – December 4, 1807), Hall formed the African Grand Lodge of North America.



"Flammas eius, Lucifer, matutinus inveniat:"

His flame, Lucifer, dawning his own creation:



1. **Rainbows, Halos, Glories, Circumzenith Arcs, Sundogs, & other Atmospheric Optics**
2. **Libyan Desert Glass (LDG) mystery solved.**
3. **Tektite Origin solved.**
4. **Megacryometeor Origin solved**
5. **Birefringence** of glass found in LDG reveals reason for double suns, comet's tail splitting, quadruple rainbow displacement
6. **Ozone** - fresh scent after a thunderstorm connected to glass plate air ionizers
7. **Fusion Crust** formation on meteorites - burnt glass
8. **Colorizing** of clouds, moon, sun
9. **Greenhouse Effect**
10. **Karman Line** - said to be the division line between atmosphere and space lies at 100 km, same height as the glass
11. **UV Radiation block**
12. **Lightning** (created by dielectric forces moving laterally near glass
13. **Elves in Upper Atmospheric Lightning** (100km)
14. **Shortwave Radio Waves** scattering (100 km) Ionosphere compares to "sheet of glass"
15. **Operation Fishbowl - Starfish Prime** - mission to blow a hole in the glass for space entry/exit
16. **Superior Mirages/Fata Morganas** - Refraction of Glass Sky creates "horizonal" crease
17. **Meteor Showers / Iridium Flares** - space particles skidding off glass sky and returning up into inner-space orbit
18. **Red Shift**- all stellar spectroscopy is debunked due to scientists ignoring chromatic aberration of stars caused by the glass
19. **Aberration of Light (Stellar Aberration)** - Glass sky creates slight apparent displacement of stars due to refraction
20. **Space Vehicles Heatshields** - flush surface, high temperature resistant material use to melt through glass
21. **Crookes Dark Space** - Negative charged ions create "dark space" around glass sky to make it invisible
22. **Auroras** - 100 km - Electrons from the sun hit the charged glass sky causing fluorescent glow/striations

Design

- Full in house engineering capabilities
- Latest design tools
- Rigid tubular steel dipoles
- No suspension/counterweight system
- Overall DC grounding of antenna and screen
- High-Band/Low-Band array
- 30 years of experience

Performance

- High reliability
- High availability
- High flexibility

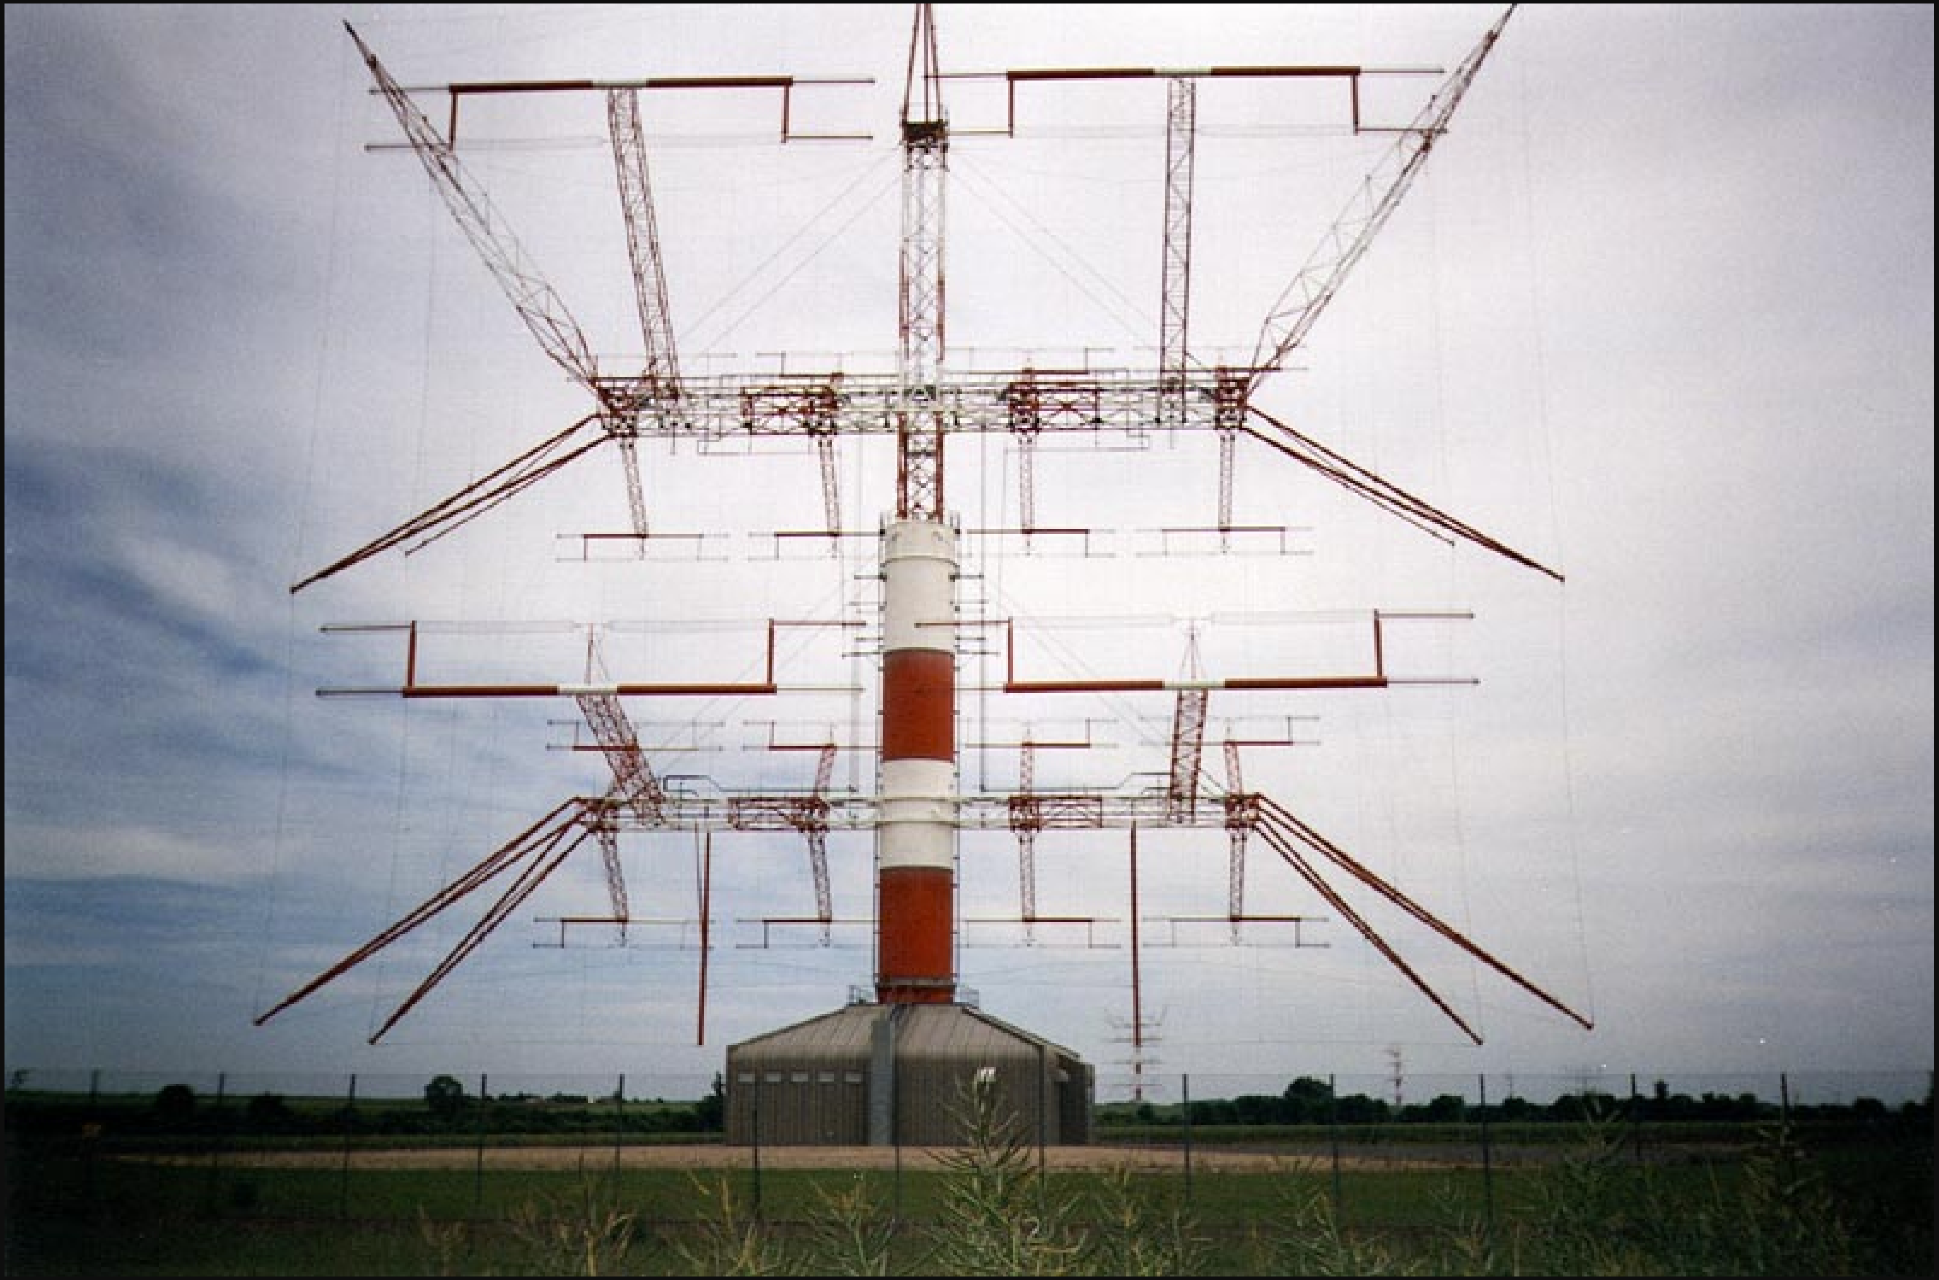
Maintenance

- Easy access to components
- No lowering of dipoles and screen

Cost efficiency

- Low life cycle cost

More than 30 years of experience
30 years of antennas on air



COMPARISON TO CURRENT TITLEHOLDER

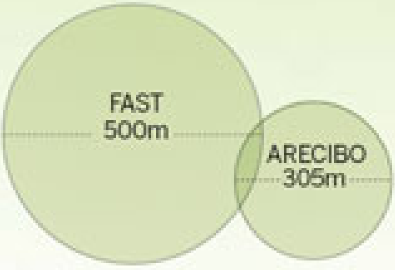
ARECIBO

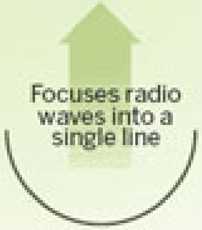
Since it was constructed in 1963 in Arecibo, Puerto Rico, this telescope had held the record as the world's largest telescope.

FAST

It's designed as a cable-net supporting structure, capable of forming a parabolic mirror and will be completed by 2016.

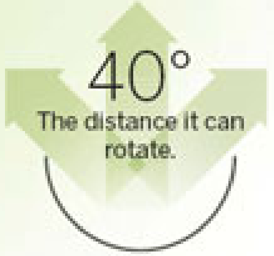
SIZE





ARECIBO

Arecibo has a fixed spherical curvature.



FAST

FAST can reshape into a paraboloidal surface.

ASTRONOMICAL GARDEN

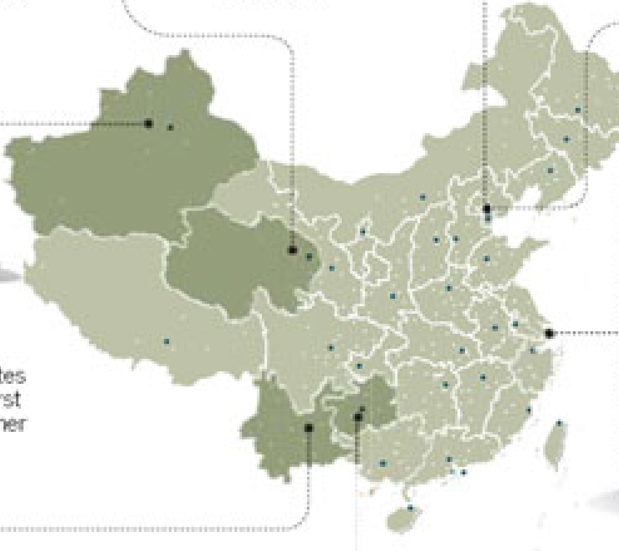
URUMQI NANSHAN
25m
Radio telescope
Built in 1994 in Urumqi, Xinjiang.
Missions: Pulsar research. Determines orbits for the Chang'e lunar satellite and other lunar projects.

QINGHAI DELINGHA
13.7m Millimeter-wave radio telescope
Built in 1990 in Delingha, Qinghai.
Mission: Interstellar molecular spectroscopic research.

MIYUN
50m
Radio telescope
Built in 2005 in Miyun county, Beijing.
Mission: Long-term monitoring of a group of known millisecond pulsars.

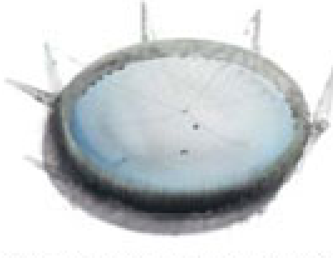
MIYUN
Synthesis radio telescope
Built in 1983 in Miyun county, Beijing.
Missions: Northern sky survey and observation of Supernova Remnant and interplanetary scintillation.

KUNMING
40m
Radio telescope
Built in 2006 in Kunming, Yunnan province.
Mission: Successfully completes the VLBI tracking of China's first lunar probe Chang'e-1 with other Chinese telescopes.



SHANGHAI SHESHAN
65m
Radio telescope (under construction)
Built by 2012 in Sheshan district, Shanghai.
Missions: Finds applications in deep space exploration and basic astronomy research and assists China's lunar exploration program.

SHANGHAI SHESHAN
25m
Radio telescope
Built in 1986 in Sheshan district, Shanghai.
Mission: Assists the VLBI (Very Long Baseline Interferometry) network.



GUIZHOU PINGTANG
500m
Aperture spherical radio telescope (under construction)
Built by 2016 in Pingtang county, Guizhou province.
Missions: Surveys neutral hydrogen in the Milky Way and other galaxies, detects faint pulsars, looks for shining stars and listens for possible signals from other civilizations.

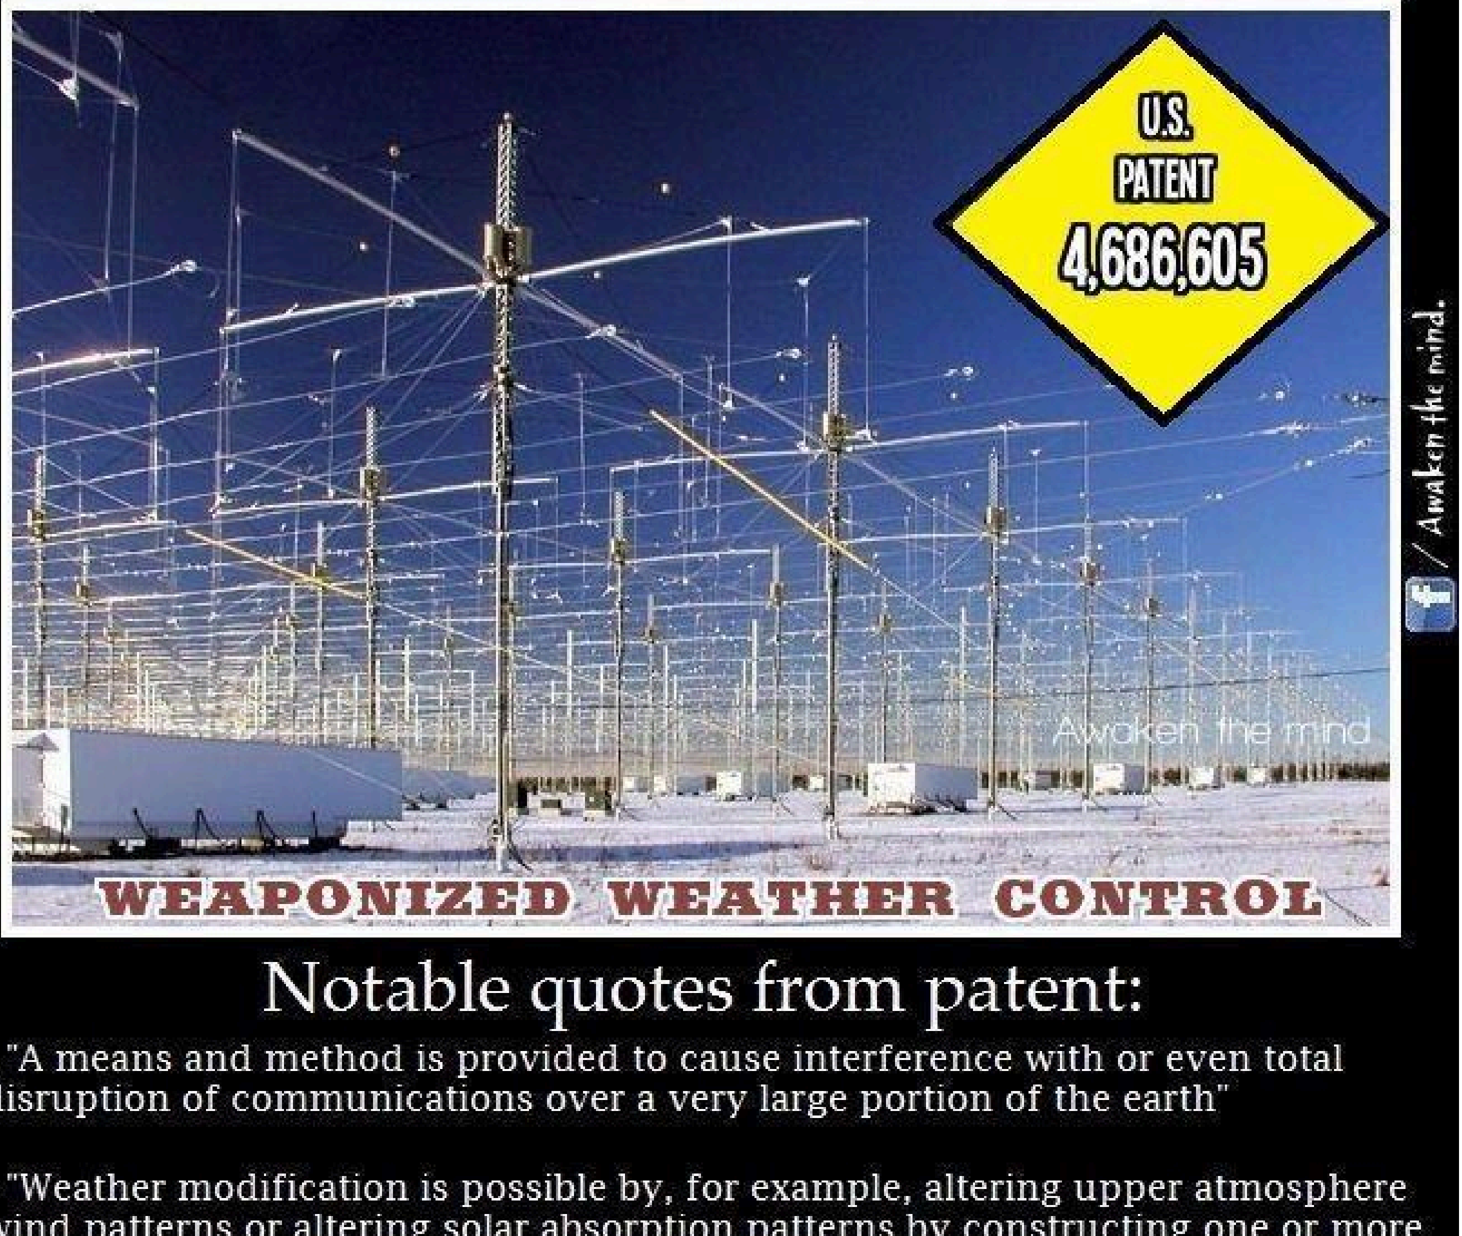
HAARP



U.S.
PATENT
4,686,605
/ Awaken the mind.
Awaken the mind
WEAPONIZED WEATHER CONTROL

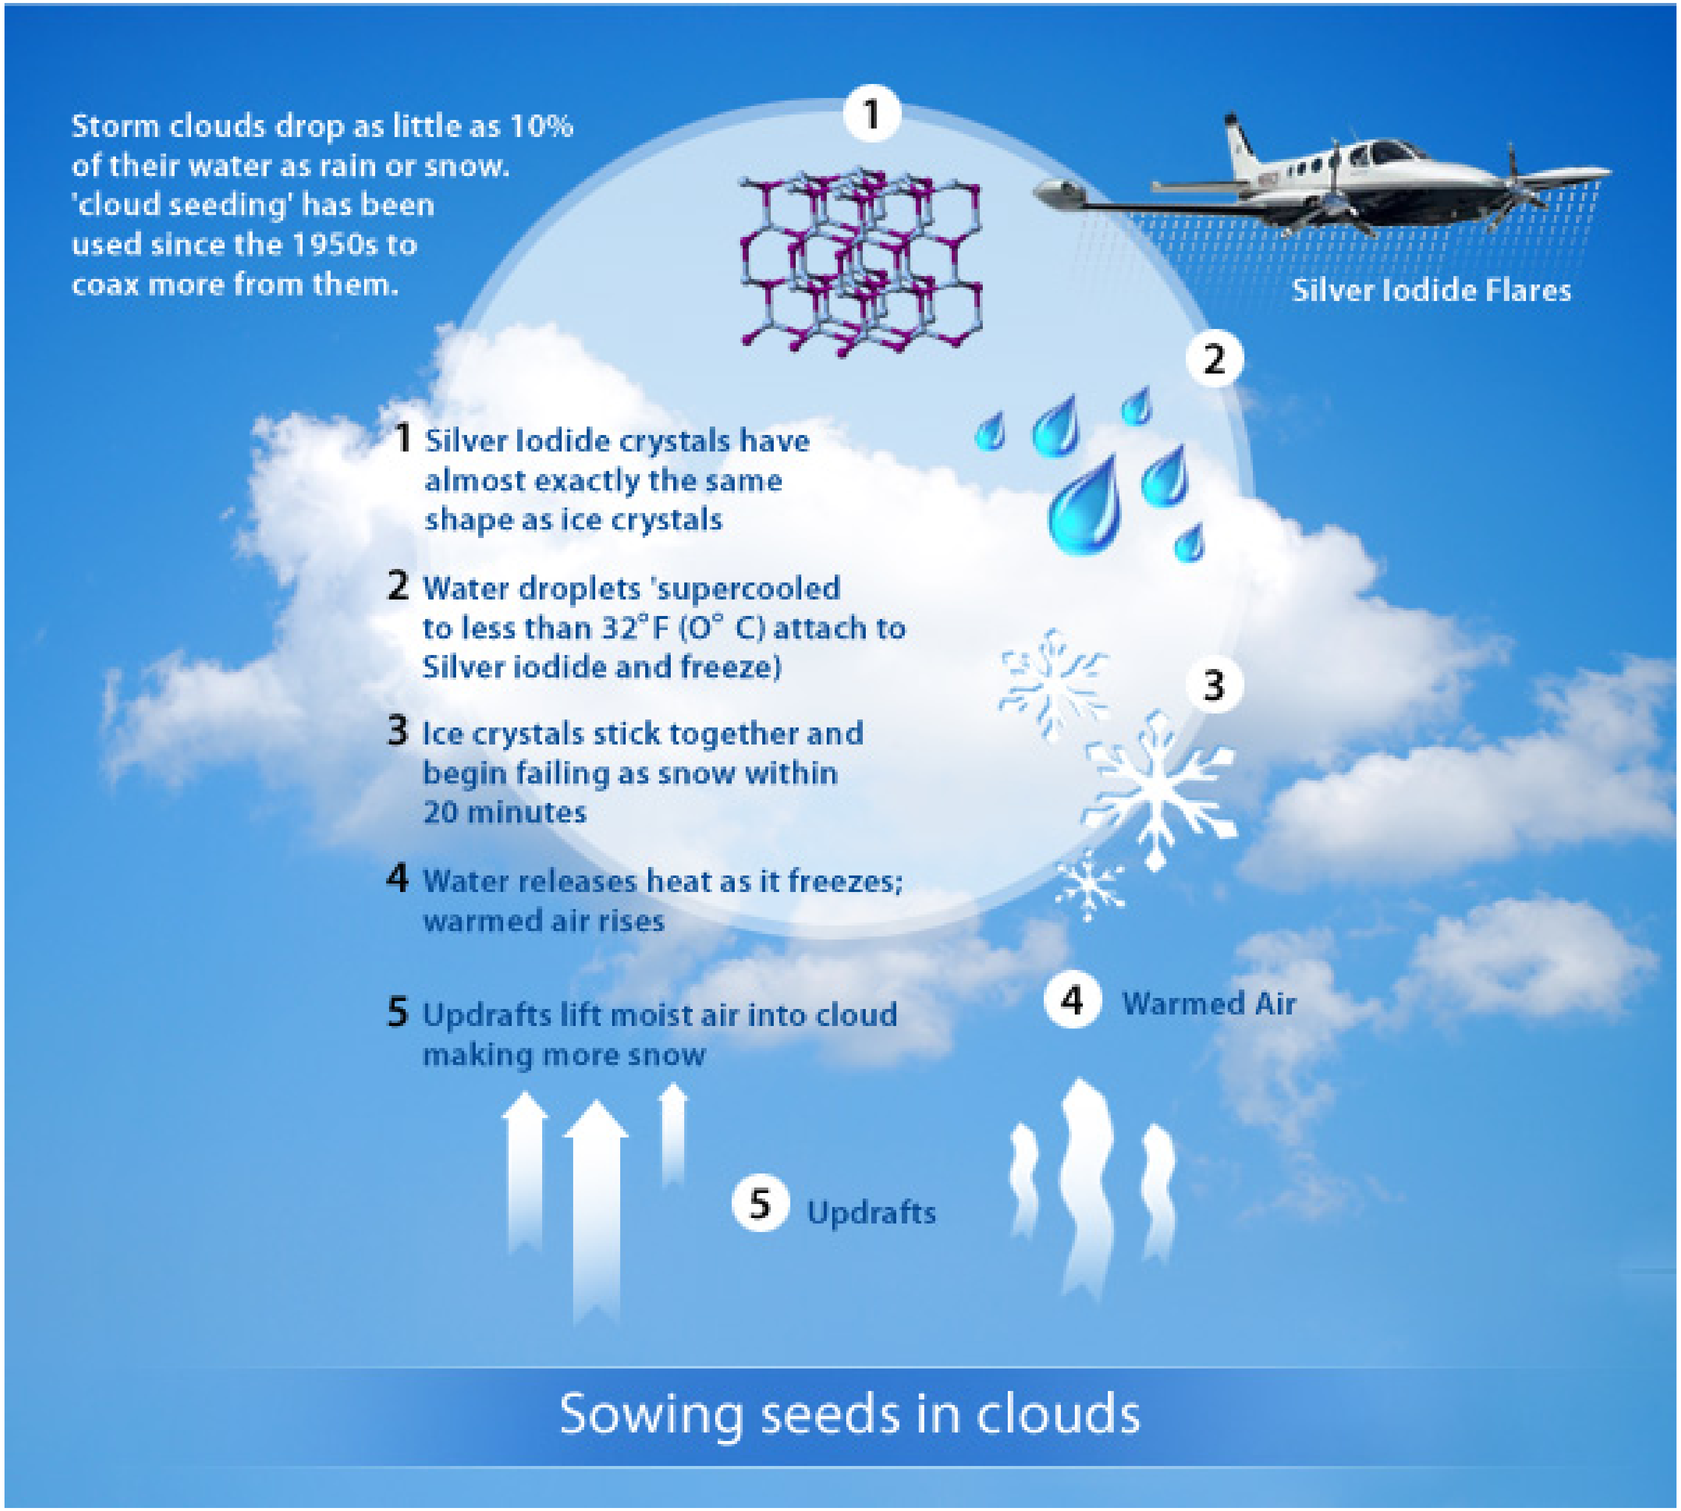
Notable quotes from patent:

- "A means and method is provided to cause interference with or even total disruption of communications over a very large portion of the earth"

- "Weather modification is possible by, for example, altering upper atmosphere wind patterns or altering solar absorption patterns by constructing one or more plumes of atmospheric particles which will act as a lens or focusing device."

- "The earth's magnetic field could be decreased or disrupted at appropriate altitudes to modify or eliminate the magnetic field."

Sowing seeds in clouds



Storm clouds drop as little as 10% of their water as rain or snow. 'cloud seeding' has been used since the 1950s to coax more from them.

1 Silver Iodide crystals have almost exactly the same shape as ice crystals

2 Water droplets 'supercooled to less than 32°F (O° C) attach to Silver iodide and freeze)

3 Ice crystals stick together and begin failing as snow within 20 minutes

4 Water releases heat as it freezes; warmed air rises

5 Updrafts lift moist air into cloud making more snow

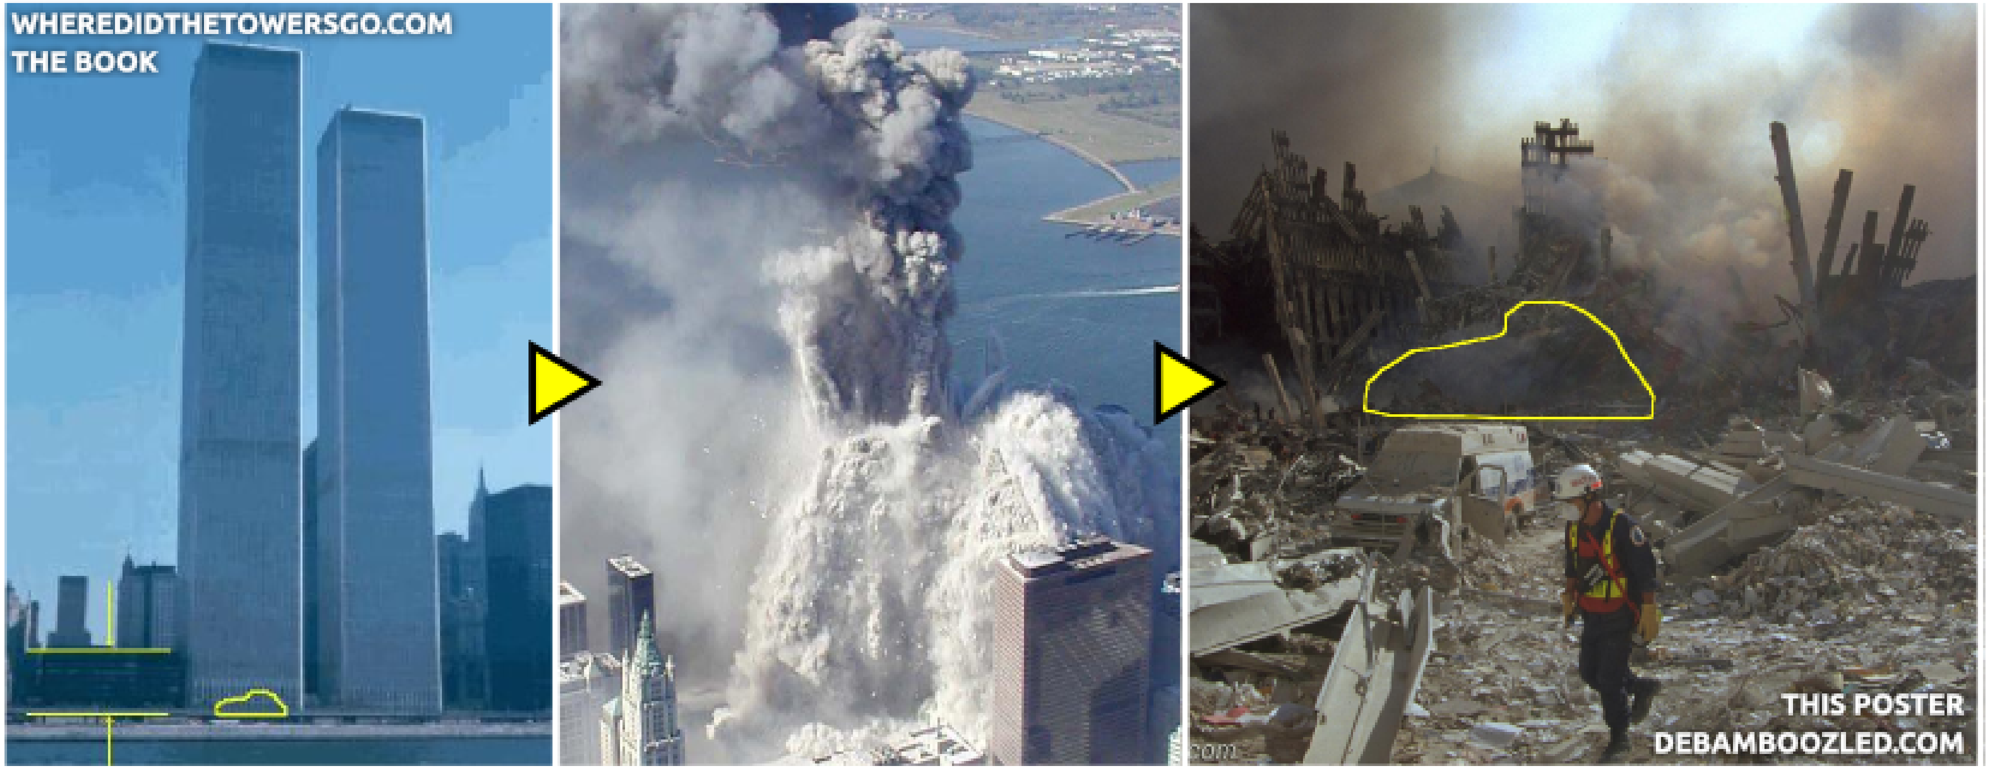
WHERE DID THE TOWERS GO?

THE EVIDENCE OF DIRECTED FREE-ENERGY TECHNOLOGY ON 9/11, BY DR. JUDY WOOD



THEY LITERALLY TURNED TO DUST IN MID-AIR

"They didn't burn up, nor did they slam to the ground, but turned into dust in mid-air" Dr. Judy Wood - "Although they were demolished in such a way as to look as if they fell, they did not fall at all" John Lash - "Those towers literally disintegrated, they went into dust." Jesse Ventura - "A plane hitting the building, should not turn the buildings into dust." George Noory - "Arguably the most important book of the 21st century." Richard D. Hall - "If you don't have Dr. Judy Wood's book, do yourself a favor; buy it, read it." Mel Fabregas

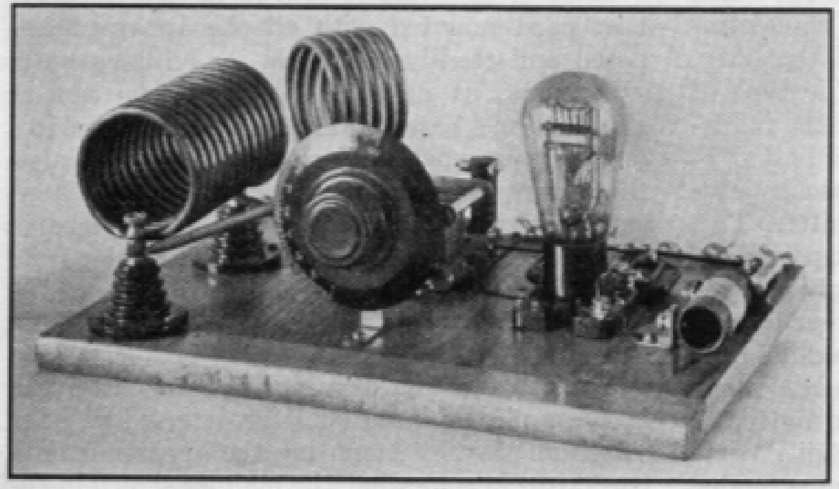

FIG. 703 — THE LOW-POWER SINGLE-TUBE TRANSMITTER

The plate tank circuit is at the left. The grid coil, leak and grid condenser are to the right of the Type 10 tube. The antenna coil is shown swung away from the plate coil to give loose antenna coupling.

Late last fall I saw an announcement regarding the upcoming '19
(AWA). Transmitters used during the event must only utilize 192
transmitters have to utilize self-excited oscillators! Listening-in o
imagine how different the bands must have sounded back in the l
heard sounded wonderful, considering the simplicity of the trans
came after watching and listening to W0VLZ's (Neil) superb You
watch these without wanting to roll-up their sleeves and start bui

After some research into the 1929 transmitter style, it became ap
Tuned (TNT) design. I can well imagine the countless late night l
simpler off-shoot of the TPTG design.

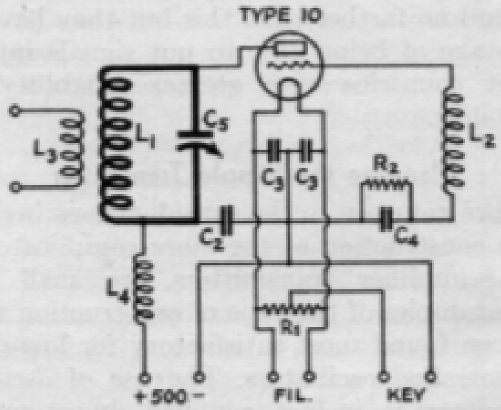

FIG. 704 — THE CIRCUIT OF THE TRANSMITTER

L_1, L_2 and L_3 — Plate, grid and antenna coils. The specifications are given under the illustration of the coils.

L_4 — A commercial "short-wave" receiving-type radio-frequency choke will do or one can be made by winding a two-inch length of half-inch tubing or wooden dowel with No. 38 d.s.c. or d.c.c. wire.

C_2 — 2000-µµfd. (.002 µfd.) mica fixed condenser, receiver type, if plate voltage does not exceed 500.

C_3 — 5000-µµfd. (.005 µfd.) mica fixed condenser, receiver type.

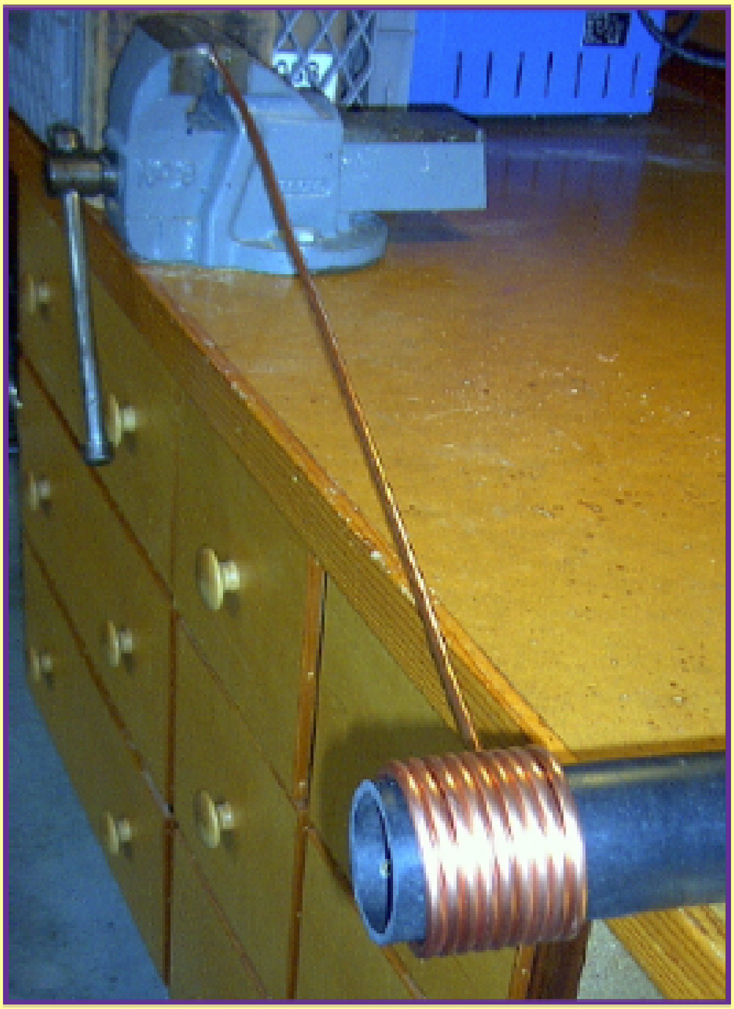
C_4 — 250-µµfd. (.00025 µfd.) mica fixed condenser, receiver type.

C_5 — 500-µµfd. (.0005 µfd.) variable condenser. Any good receiving condenser will be satisfactory.

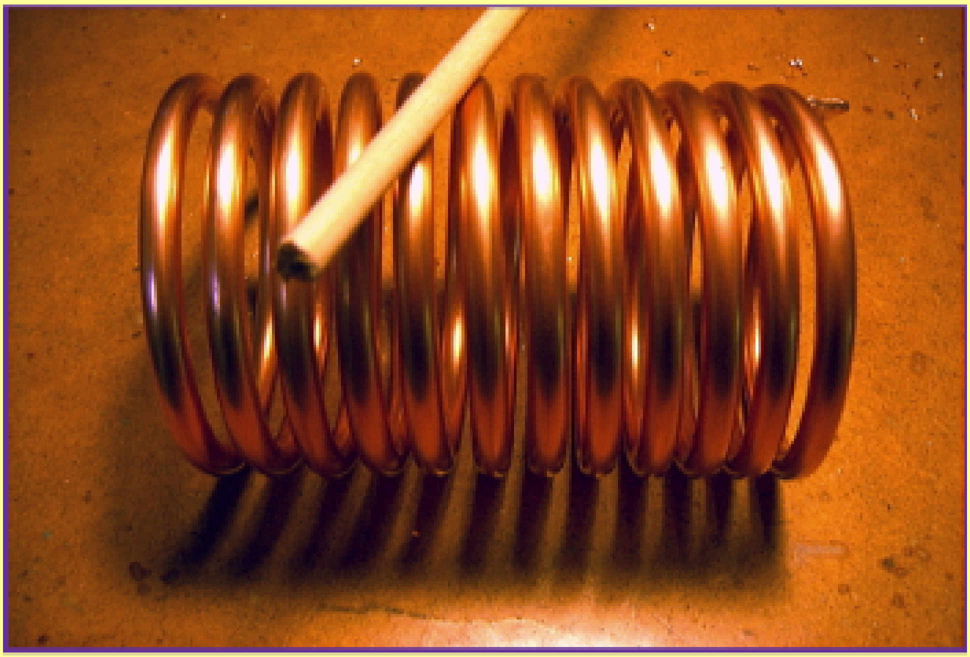
R_1 — Center-tapped resistor, 75 to 100 ohms total resistance.

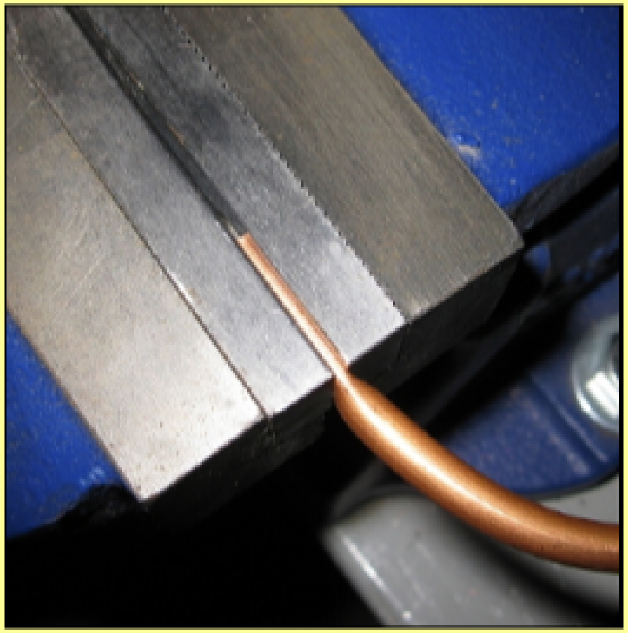
R_2 — Grid-leak resistor, 10,000 ohms. Any small resistor rated at 5 watts or more will do.

Three General Radio or similar stand-off insulators will be necessary, as well as 8 Fahnestock clips, some miscellaneous small machine screws and nuts, and a few feet of bus wire.

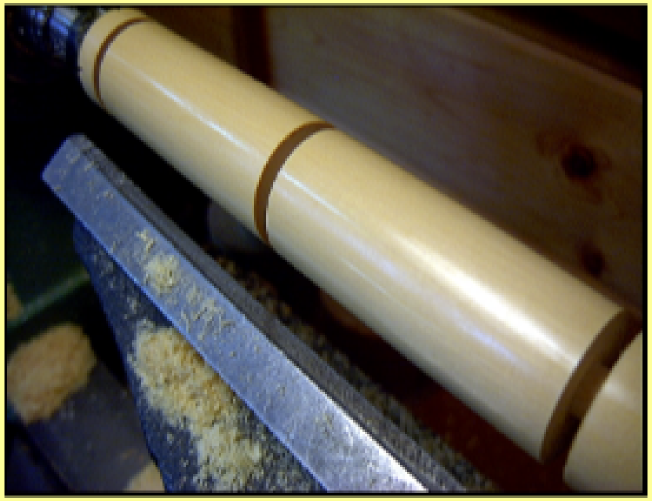


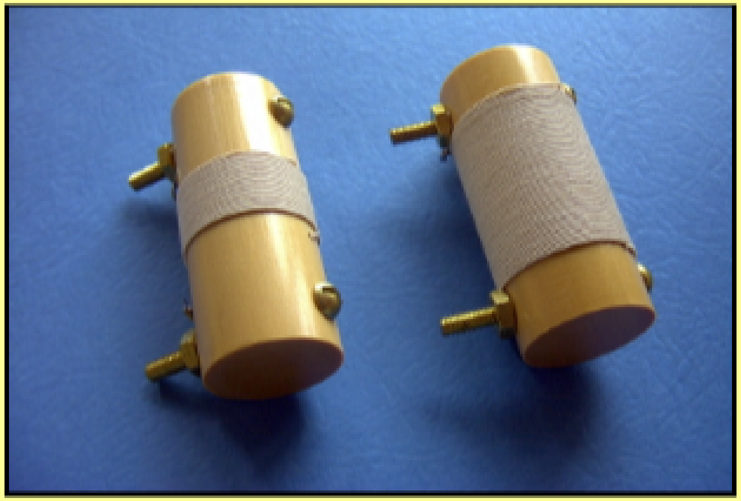
r coils. Once the proper number of turns is reached it is just a matter of flattening and drilling the ot
, I wound a plate coil for 40m as well. I haven't been brave enough to try the TNT on 20m yet but I w



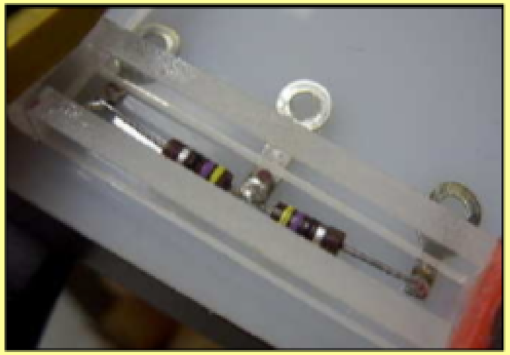


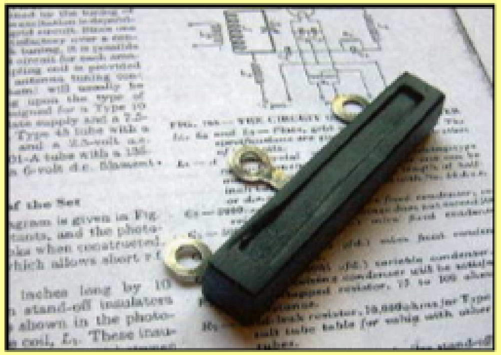
ither wound on bakelite tubing or on well-sealed wood dowel. Not having any bakelite made the choice any easy one. The 1" forms were made from some Yellow C





resistor was fabricated to resemble the original bakelite-enclosed 'Pilot' style, popular in the late 20's.The pictures indicate how this was done and the finished result. The small plexi-glass form was filled with black Fin
emoved and the entire package was baked in the kitchen toaster oven at its lowest temperature for several hours. This achieved the desired hardening effect and a suitable reproduction Pilot filament resistor.





reproduction also, of an early 'Lavite' model. The ends of a new wire-wound resistor were removed and found to be made from brass. These ends were then fitted to the body of an older style 10K resistor, soldered, pai
y across the terminals of the grid cap. I found out later that the actual value of the grid leak is quite critical in the TNT. I tried various values and luckily the one I had manufactured turned out to be perfect. My earlier
UX-210) required a far larger grid leak to produce best keying and good output. If you are making your own grid leak I would recommend that the value be optimized first, before the grid leak is built in its final form.

Dr. Baugh & the Pre-Flood Environment

Director of the Creation Evidence Museum in Glen Rose, Texas, Dr. Carl Baugh has invented and patented a 'Hyperbaric Biosphere' chamber to test Biblical claims regarding pre-flood atmosphere and magnetic conditions based on Genesis.

Genesis states that life on earth was created 'perfect' and designed to live forever. It also states that after the fall of man, all elements of which everything is made, were cursed. Genesis then records the gradual degeneration of the whole of creation until the flood of Noah followed by an increasing rate of degeneration as time progressed.

If the dates and years reported use the same standards we do in modern times, then there is an overlapping of pre-flood humans with that of post-flood survivors where the pre-flood humans lived many more years.

The average age of man prior to the flood was approximately 920 years, after the flood, mans lifespan declined by 250 years until the time of Christ when lifespans averaged 70 years. Tests indicate simulation of a pre-flood environment would produce conditions of increased longevity, cellular growth and a change in molecular structures.

Dr. Baugh's experiments with his special hyperbaric biosphere have produced fascinating results that indicate potential methods to heal and/or rejuvenate people today. NASA has even requested Dr. Baugh's research and discoveries to determine their applicability to the space program.

Hyperbaric Biosphere

Experiments carried out in this pre-flood atmospheric chamber have produced amazing evidence supporting the biblical record of the pre-flood world.

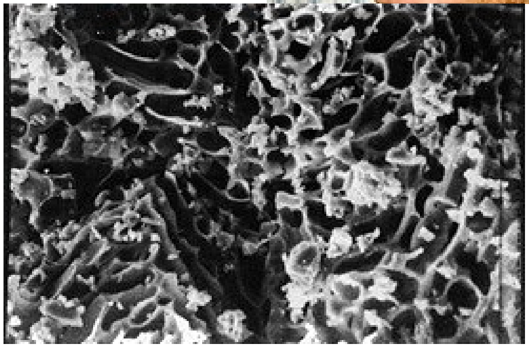
Some examples include;

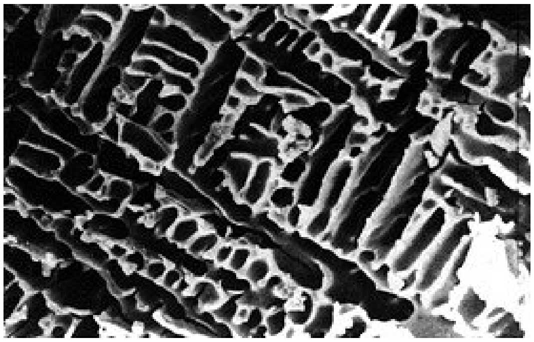
extended life span of drosophila fruit flies up to three generations, molecular change of venom in copperhead snakes to a non-toxic state, accelerated growth of piranha fish - from 2" to 16" over a 2.5 years period.

The Hyperbaric Biosphere patent allows for the ability to vary the mix of gases comprising the atmosphere in the chamber as well as to vary the electromagnetic field intensity, frequency and duration.

Dr. Baugh and an unidentified associate handle deadly copperhead snakes used in an experiment to test whether increased oxygen levels, as would be experienced in pre-flood conditions, might alter the physiology of the snakes.

He contends an artificial pre-flood environment could be duplicated with increased oxygen, higher pressure and the use of higher EM fields





Another investigation at the creation evidence museum, the gnarled 'spaghetti-like' formation of copperhead snake venom as seen under the scanning electron microscope before the copperhead snake was 'housed' in a small hyperbaric chamber.

After four weeks in the hyperbaric chamber, venom from the same copperhead snake shows a much less distorted structure (less gnarled) indicating a lowering of the toxicity level. Conditions in the hyperbaric chamber are seeking to provide the type of environment that existed in the time prior to the great flood.

Additional information that might be of use;

It has been estimated by researchers at the University of Illinois that the atmospheric pressures in the earliest beginnings of life on earth, could have been as much as 29.4 pounds per square inch, twice the current sea level pressure (14.7 psi at sea level).

1) oxygen content would have been about 30% instead of the 21% we experience today

2) an open wound could heal overnight under these conditions

3) this atmospheric condition would support human life lasting several hundred years

A related post sent to a discussion list recounts the following unconfirmed information about rejuvenation effects noted by aquanauts living underwater for periods of 30 days or greater.

CJT Enterprises wrote:

Hi everyone,

A friend of mine who worked for the NSA related an experiment that was conducted by NASA. Three scientists lived on the floor of the ocean for about 1-3 months in a biosphere.

When they left they were all middle aged with graying hair and low libidos.

When they returned their hair was clear of gray, their wrinkles had started to disappear, and their sex drive was so increased that their wives complaied to NASA about it.

It turns out that certain glands and organs were "reactivated." One in particular was the gland that lies over the top of the heart. Blood tests showed unusual hormones. Hormones that are normally associated with the growth of young children.

f you check the Creation Research Center and look up the url for the Creation Research Institute you can then find the geologist who recreated the atmosphere of the flood in a container. I havent checked for his name yet. Been behind on my page and other projects, but I am having a pastor friend look into it for me.

What if we take this knowledge and build a "room" that emulates the atmosphere of the Earth before the flood and sleep in it for 8 hours a day? What effects might it have? My friend from the NSA said that for every day spent in there one year was added onto your life until you maxed out at 1000.

Closed ecological system and method for supporting life
US5935516

An apparatus to contain a closed ecological system, wherein the apparatus includes a closed, air-tight chamber to contain an atmosphere. The chamber includes at least one access opening designed to allow plants, animals, raw materials, and other items to be placed within the chamber. The chamber includes a system for introducing oxygen and/or carbon dioxide into the chamber and for maintaining the oxygen and/or carbon dioxide at a predetermined concentration percentage of the atmosphere. Preferably, the closed ecological system of the present invention also includes a system for establishing a magnetic field within the chamber of a predetermined strength and orientation. The chamber may also include systems for elevating the atmospheric pressure within the chamber and for maintaining the atmosphere within the chamber at a predetermined temperature and humidity level. The chamber may also include a specialized lighting and sound system to establish light and sound of a predetermined intensity, frequency, and wavelength within the chamber. A satellite chamber may be provided in selective fluid communication with the closed ecological system for providing plants, animals, or chemical processes with short-term exposure to the conditions of the closed ecological system. The present invention is also directed to a method of establishing and maintaining a closed ecological system to support plant and animal life and to aid in the development, discovery, and/or production of new and improved chemical compounds that may be used as pharmaceuticals and other chemical compounds.

FIELD OF INVENTION

The present invention relates generally to closed ecological systems, and more particularly to a method and apparatus for establishing and maintaining a closed ecological system wherein the environment within the closed system is controlled such that plant and animal life can exist to its more optimal potential and thrive, the effects and causes of plant and animal disease can be reduced and/or eliminated, mental well being of animals can be fostered, and new and improved pharmaceuticals and other chemical compounds (organic and inorganic) can be discovered and/or synthesized.

BACKGROUND OF THE INVENTION

The environment in which we live with plants and other animals has changed since biological systems first appeared. The composition of the air we breathe has continued to change. For example, there is reason to believe that the concentration of oxygen found within the air has decreased over time. The climate, including temperature, humidity, rainfall, snowfall, and the like has also been changing. It is further theorized that other important changes in the environment of the earth over time have been the marked decrease in atmospheric pressure, a decrease in the concentration of carbon dioxide in the earth's atmosphere, changes in the strength and orientation of the earth's magnetic field, and the change in the intensity and characteristics of the light radiation to which we are exposed. Furthermore, sounds of nature such as singing birds have become increasingly difficult to encounter due to a general decrease in the population of songbirds.

Many of the above and other changes are a natural result of the maturing of the earth. Other changes to the earth's environment are caused by purely natural events--volcanic eruptions, earthquakes, tidal waves, glaciers, and the like alter the earth itself and the surrounding atmosphere. Other changes to the earth and its atmosphere are due entirely to man. Pollution, overpopulation, overdevelopment, overutilization of natural resources, fishing, hunting, and farming have all altered our world. As the human population continues to increase, the pace at which these changes occur will inevitably increase.

These changes in the earth and the surrounding environment have had a detrimental impact on plants and animals including man. Certain plants and animals have vanished from the earth, unable to adapt to the changed earth. Many of the remaining varieties of plants and animals have found it difficult to thrive. The fruits and vegetables of trees and plants have lost taste and nutritional value. Animals, including humans, are increasingly disease stricken, weak, and otherwise unhealthy. Humans seem to have lost their general sense of well being, leading to an increase in depression, suicides, crime, violence, sickness, and other social and physical ailments and have become increasingly lethargic with shortened attention spans.

The increasing physical and mental ailments of humans has led to a constant search for new and improved pharmaceuticals to combat these sicknesses. As one example, scientists are constantly searching the far reaches of the planet for naturally occurring antiviral and antibiotic substances. Once such naturally occurring substances are discovered, scientists may attempt to synthesize these drugs in a laboratory. While much progress has been made in the field of locating and synthesizing these compounds for use as pharmaceuticals, many ailments currently have no known effective treatment drugs or the causative agents have been able to adapt or modify their own structure to develop a resistance to such treatments. For example, many cancers and AIDS have been particularly resistant to pharmaceuticals located and/or synthesized using conventional methods in standard environmental conditions. It is believed that the changes in the earth's environment have prevented certain drugs from being created in nature, discovered, and/or synthesized, and has prevented the compounding of certain organic and inorganic elements.

SUMMARY OF THE INVENTION

It is therefore an object of the present invention to solve the above and other problems caused by changes in the earth and its surrounding environment.

It is also an object of the present invention to provide a closed ecological system including an atmosphere with an elevated oxygen content.

It is another object of the present invention to provide a closed ecological system including an atmosphere with an elevated atmospheric pressure.

It is another object of the present invention to provide a closed ecological system with an atmosphere having an elevated concentration of carbon dioxide.

It is a further object of the present invention to provide a closed ecological system including a low level magnetic field.

Yet another object of the present invention is to provide a closed ecological system including specialized lighting and sound.

Still a further object of the present invention is to provide a closed ecological system with a controlled temperature, humidity, and other climate variables.

Another object of the present invention is to provide a closed ecological system having an overall environment that is favorable to the natural formation and/or the manufacture of improved compounds used to manufacture pharmaceuticals for the treatment of sickness and disease.

The present invention accomplishes these and other objects by providing an apparatus to contain a closed ecological system, wherein the apparatus comprises a closed, air-tight chamber to contain an atmosphere, and wherein the chamber includes at least one access opening. The access opening is designed to allow plants, animals, raw materials, and other items to be placed within the chamber. The chamber includes means for introducing oxygen and/or carbon dioxide into the chamber and means for maintaining the oxygen and/or carbon dioxide at a predetermined concentration percentage of the atmosphere. Preferably, the closed ecological system of the present invention also includes means for establishing a magnetic field within the chamber of a predetermined strength and orientation. The chamber may also include means for elevating the atmospheric pressure within the chamber and means for maintaining the atmosphere within the chamber at a predetermined temperature and humidity level. The chamber may also include a specialized lighting and sound system to establish light and sound of a predetermined intensity, frequency, and wavelength within the chamber. A satellite chamber may be provided in selective fluid communication with the closed ecological system for providing plants, animals, or chemical processes with short-term exposure to the conditions of the closed ecological system.

The present invention is also directed to a method of establishing and maintaining a closed ecological system to support plant and animal life and to aid in the development, discovery, and/or production of new and improved chemical compounds that may be used as pharmaceuticals.

DETAILED DESCRIPTION OF THE INVENTION

Reference will now be made in detail to the present preferred embodiments of the invention, examples of which are illustrated in the accompanying drawings. Wherever possible, the same reference numbers will be used throughout the drawings to refer to the same or like parts.

An apparatus for establishing, containing, and maintaining a closed ecological system in accordance with the present invention is shown generally at 10 in FIGS. 1-7 and comprises an air-tight, substantially hollow chamber 20 made of plastic, metal, fiberglass, or any other suitable material. Chamber 20 includes a sealable access opening such as hinged door 22 provided with suitable air locks 24 and seals (not shown) to ensure that door 22 does not reduce the air-tight integrity of the chamber 20. Chamber 20 is designed to contain therein an atmosphere, plants, animals, objects and any other desired components of a closed ecological system such that plants and animals may live therein and such that chemical reactions such as the production of pharmaceuticals can be carried out therein. Chamber 20 may be of any size desired such that the ecological system established and maintained therein may be of any suitable size. Chamber 20 may only be large enough to contain a few small plants and animals, or chamber 20 may be large enough to contain a community of numerous human beings. As shown, chamber 20 is sufficiently large to contain at least one human being and several plants and animals. Chamber 20 may include air-tight windows 26 formed therein or in door 22 thereof using suitable glass or plastic to allow those outside of the chamber 20 to observe the plants, animals, and any other animals, objects and/or conditions inside of chamber 20. Door 22 may be opened to remove, add, or reorient specimens as desired, after depressurization has returned internal pressure to ambient conditions. Windows 26 are designed to filter ultra-violet (UV) light to prevent unwanted UV light from affecting the ecological system contained within chamber 20. Specifically, UV light causes or encourages the formation of "free radicals" that are thought to be harmful to animals.

Chamber 20 is supported upon a base 12 to prevent the unwanted movement of the chamber 20 and other components of the apparatus 10. A sub-chamber or premixing chamber 28 (FIGS. 4 and 5) is preferably provided and is in selective fluid communication with chamber 20 through pipes or other conduits 27. Sub-chamber 28 provides a means for premixing the gases and liquids to be added to chamber 20 to ensure that such gases and liquids are uniformly distributed within chamber 20. It should be recognized that chamber 28 may also function as a satellite chamber in selective fluid communication with chamber 20 for establishing and maintaining a closed ecological system similar to that found within chamber 20, such that plants, animals, chemical reactions and the like can be placed within the closed ecological system found within the satellite chamber for time periods that differ (usually shorter) from the amount of time chamber 20 needs to remain closed. To function as a satellite chamber, sub-chamber 28 would need to include an access opening such as a door, and would need to include at least some of the features of chamber 20 as they are set forth below. Also, if sub-chamber 28 is to be used as a satellite chamber, chamber 20 and sub-chamber must be shielded from each other with a lead shield or the like to prevent the magnetic field (discussed fully below) of one chamber 20, 28 from interfering with the magnetic field of the other chamber 20, 28. For example, in addition to conducting experiments relating to the natural creation and/or synthesis of pharmaceuticals within chamber 20, sub-chamber 28, when properly adapted as a satellite chamber, may alternatively be utilized for the same types of experiments. Various chemicals could be mixed and placed within sub-chamber 28 for a period of time, and thereafter be removed from sub-chamber 28 and examined, without opening door 22 of chamber 20 and without altering the ecological system found within chamber 20.

Conduits 27 between sub-chamber 28 and chamber 20 are selectively blocked or closed using gate valves 29 (FIG. 5) or the like so that sub-chamber 28 may be selectively "disconnected" or prevented from being in fluid communication with chamber 20 to protect the integrity of the ecological system found within chamber 20 during premixing operations. After sub-chamber 28 is "disconnected" from chamber 20, various gases and other components of the closed ecological system as described herein may be introduced into chamber 28, without altering the ecological system within chamber 20. When the gases and liquids introduced into sub-chamber 28 are properly mixed, which may occur naturally or with the aid of mixing devices such as blowers, gate valves 29 may be opened to allow the properly mixed gases and liquids to enter chamber 20 as is described below. Sub-chamber 28 includes a pressure relief valve 25 so that excess pressure may be vented from sub-chamber 28 if necessary. Those skilled in the art will recognize that the apparatus need not include a sub-chamber 28 and such is contemplated herein, although use of sub-chamber 28 is thought to be preferable. Also, those skilled in the art will recognize that any ecological system or conditions created and maintained in chamber 20 may also be created and maintained in sub-chamber 28, and for reasons of clarity, the following description will not necessarily refer to providing an ecological system within both chambers 20,28 but will instead refer primarily to chamber 20.

Apparatus 10 includes numerous components and features such that an ecological system can be created and maintained within chamber 20 and so that the characteristics of the ecological system so created and maintained, such as temperature, atmospheric pressure, humidity, magnetic field, oxygen level, carbon dioxide level, and the like may be accurately varied and monitored. One or more feeder valves such as dual ball valves 30 are provided in fluid communication with the interior of chamber 20 and are also connected to vacuum/pressure pump 38 (FIG. 5) to allow fluids such as air, oxygen, water, nutrients and others (organic and inorganic) to be communicated from the appropriate source into the ecological system found within chamber 20 through one or more valves 30. As is noted above, it is thought preferable to premix fluids in sub-chamber 28 prior to introducing the fluids into chamber 20. Feeder lines or conduits may be surrounded by a coolant or other thermal fluid to vary the temperature of the fluid in the feeder line. Because of the potentially elevated atmospheric pressure (hyperbaric pressure) within chamber 20, dual ball valves 30 are thought to provide a more effective seal to prevent the escape of gases from the chamber 20 and to otherwise protect the integrity of the closed ecological system created and maintained by the apparatus 10, although other suitable valves are known and are contemplated for use in conjunction with the present invention 10. A pressure gauge 32 is also provided to allow those outside of chamber 20 to monitor the atmospheric pressure within chamber 20.

The pressure of the atmosphere within chamber 20 may be varied as desired to provide an elevated atmospheric pressure. It is thought preferable for example to create a hyperbaric closed ecological system--i.e., a closed ecological system having an increased atmospheric pressure relative to the atmospheric pressure normally encountered on earth. It is thought most preferable to provide an environment inside of chamber 20 having an atmospheric pressure of 1 to 2 atmospheres of pressure. FIG. 5 shows a pressure sensor or transducer 36 coupled to a pressure control mechanism such as pressure control computer 37 to control and regulate the pressure inside of chamber 20 and/or 28. Transducer 36 converts air pressure into electrical signals to provide input data to pressure control computer 37 so that computer can continually monitor the air pressure within chamber 20 and adjust the same accordingly. A vacuum/pressure pump 38 is provided in fluid communication with chamber 20 so that the pressure in chamber 20 can be elevated using compressed air generated by pump 38 and transferred into chamber 20 through one or more of the valves 30. Pump 38 may also be used to create a vacuum suction to draw air from chamber 20 resulting in a low pressure environment within chamber 20. As a safety and control measure, a high pressure safety switch 35 is provided to prevent overpressurization of the chamber 20. Likewise, a low pressure safety switch 31 is provided to prevent an excessive vacuum condition from being established within chamber 20. A pressure relay 39 is provided to selectively energize vacuum/pressure pump 38 as needed to increase or decrease the atmospheric pressure in chamber 20 and a blow off valve 33 is provided in fluid communication with chamber 20 to allow excessive air pressure that may be contained therein to be rapidly vented automatically when the atmospheric pressure within chamber 20 exceeds some threshold value such as 2 atmospheres.

In addition to an elevated atmospheric pressure, the closed ecological system of the present invention 10 preferably includes an atmosphere within chamber 20 having an elevated oxygen concentration relative to the concentration of oxygen normally found in the air surrounding the earth. Specifically, it is thought preferable to maintain a concentration of oxygen within chamber 20 such that the oxygen is equal to 22%-30% by volume of the atmosphere contained within chamber 20 when the atmospheric pressure is in the range of 1-2 atmospheres. For long term occupation within chamber 20 the oxygen level is most preferably maintained at 22%-24% by volume at 2 atmospheres of pressure, while for short term occupation, a month or less, the oxygen level within chamber 20 may be elevated to 26%-30% by volume at 2 atmospheres of pressure.

A source of oxygen such as a pressurized holding tank 40 or the like is provided to supply oxygen to the system 10. Alternatively, oxygen may be generated by an electrolysis process. Oxygen supply tank 40 is in fluid communication with vacuum/pressure pump 38 and chamber 20 using the appropriate conduits and connections. A valve assembly such as oxygen solenoid valve 42 is controlled by a control mechanism such as oxygen control computer 44 which is provided between supply tank 40 and pump 38 to regulate the flow of oxygen to pump 38 and into chamber 20 through one or more valves 30 (FIG. 1). An oxygen sensor 46 is provided in one or both chambers 20, 28 to sense the concentration of oxygen therein. Sensor 46 provides the concentration to oxygen control computer 44 as input so that computer 44 may determine if oxygen solenoid valve 42 should remain closed or should be opened to allow more oxygen to enter chambers 20, 28. A filter 82 is preferably provided between oxygen supply tank 40 and pump 38 to filter any contaminants from the oxygen.

By combining an increased level of oxygen concentration with a hyperbaric atmospheric pressure inside of chamber 20, the amount of oxygen absorbed by animals within the chamber 20 is maximized. This increased absorption of oxygen by the animals, including humans, leads to increased physical healing through the increased oxygen absorption of the cells of the animal, increased immunity, an increased level of mental awareness, and a general sense of well being for the animals that spend time within the closed ecological system created and maintained by apparatus 10. The increased absorption of oxygen by the animal cells raises the internal temperature of the cells, resulting in the damage to cancerous cells which have been found to have a lower resistance to heat than ordinary cells. As is discussed below in relation to FIGS. 9 and 10, the increased concentration of oxygen combined with an elevated atmospheric pressure, alone or in combination with other aspects of the closed ecological system found within chamber 20, has been found to result in the natural production of a superior snake venom having medicinal properties. Also, it is believed that the in increased oxygen level and atmospheric pressure contributes to improving the reactions among various chemicals which can lead to the production of superior chemical compounds such as very effective pharmaceuticals that may be used to treat illnesses for which there are currently few or no effective treatment drugs.

In conjunction with increasing the concentration of oxygen in chamber 20, it may also be desirable in certain circumstances to increase the concentration of carbon dioxide (CO2) in chamber 20. It has been theorized that an increased concentration of carbon dioxide lengthens the gestation period for mammals. This may be desirable to prevent premature births (births before the end of the normal gestation period for any particular mammal) or to lengthen the gestation period beyond normal to increase the development of the fetus. Carbon dioxide normally comprises approximately 0.026% by volume of the air normally encountered by mammals on earth. The apparatus 10 allows a closed ecological system to be created wherein the concentration of carbon dioxide therein may be elevated to approximately 0.1%-0.3% by volume. This increased level of carbon dioxide, in conjunction with an elevated atmospheric pressure of approximately 2 atmospheres leads to the lengthened gestation period for mammals. It has also been found that raising the level of carbon dioxide assimilation in plants enhances plant production of stalks, leaves, and fruit.

As is shown in FIG. 5, a supply of carbon dioxide such as a pressurized carbon dioxide supply tank 50 or the like is provided in fluid communication with pump 38, through filter 82 designed to remove contaminants from the carbon dioxide. Pump 38 is in fluid communication with chamber 20 through one or more dual ball valves 30. A carbon dioxide sensor 52 is capable of sensing the concentration of carbon dioxide in the chambers 20, 28. A control mechanism such as carbon dioxide control computer 54 receives the concentration of carbon dioxide from sensor 52 as input and determines whether to increase the concentration thereof. If more carbon dioxide is needed within chamber 20, carbon dioxide control computer 54 causes a valve assembly such as carbon dioxide solenoid valve 56 to open, thereby allowing carbon dioxide to flow from supply tank 50 to pump 38 and thereafter into chamber 20 through one or more valves 30.

The apparatus 10 of the present invention also includes systems to control the temperature and humidity of the air within chamber 20 and also includes an air filtration system to remove contaminants from the air. A temperature sensor 60 is provided within chamber 20 to sense the temperature therein. Sensor 60 is coupled to a temperature control unit 62 which may be a computer or a simple thermostat, which is coupled to a heating and cooling pump 64. Heating and cooling pump 64 is capable of adding heat to or removing heat from chambers 20, 28 as desired to control the temperature therein. Heating and cooling pump 64 is coupled to chambers 20,28 through a check valve 68 to sub-chamber 28 and main chamber 20. Preferably, the temperature inside of chambers 20 and 28 is maintained in the range of 70 DEG -80 DEG Fahrenheit (F.) at all times. The temperature may be decreased to approximately 70 DEG F. at "night" and maintained at approximately 80 DEG F. during the "day." Of course, the terms "day" and "night" do not necessarily refer to the time of day outside of the chambers 20, 28 although "day" and "night" within the chambers 20, 28 may be controlled to correspond to conditions outside of the chambers 20, 28. Electric lights 25 (FIGS. 4 and 6) are provided to shine light into the chamber 20 through windows 26. Lights 25 receive power from a power supply 21 and are also connected to a control box/timer 23 that allows an operator of the apparatus 10 to vary the intensity, duration, and wavelength of each light 25. Lights 25 are preferably filtered to provide a wavelength primarily in the range of 6365 Angstroms which results in a magenta light. Therefore, "day" may occur anytime lights 25 are on while "night" may occur anytime no light is shining through windows 26 because of darkness surrounding chamber 20 or because of shades or the like being placed over windows 26.

The humidity within chambers 20, 28 is also closely monitored and is maintained in the range of 40%-60%. A humidity sensor 70 is provided within chamber 20 to sense the percentage of moisture found in the atmosphere within chamber 20 and is coupled to a humidity control unit 72 which may include a gravity collection/injection valve apparatus or any other suitable humidity control apparatus. Humidity control unit 72 is coupled to a computer system 74 that is capable of controlling the humidity control unit 72 to maintain the humidity within chambers 20, 28 at the desired 40%-60%. Humidity control unit 72 and computer system 74 are coupled through a switch 76 to vacuum/pressure pump 38 such that pump 38 may be selectively energized through switch 76. Pump 38 is coupled to a desiccator unit 78 which is in fluid communication with chambers 20, 28. Upon being energized through switch 76, pump draws air from within chambers 20, 28, through desiccator unit 78 wherein moisture is removed from the air. The dehumidified air is then returned into chamber 20 through one or more valves 30. Because of the closed nature of closed ecological system created and maintained in apparatus 10, it will not normally be necessary to add humidity to chambers 20, 28, although such is contemplated and may be accomplished by the addition of a humidifier to the apparatus 10.

Apparatus 10 is also provided with an air filtration system comprising an air filter 80 provided in fluid communication with vacuum/pressure pump 38 and heating and cooling pump 64 such that any air introduced into chambers 20, 28 using vacuum/pressure pump 38 and/or heating and cooling pump 64 is first filtered of any airborne contaminants such as dust and bacteria. Both filter 80, and filter 82 discussed previously, may be a conventional filter media such as a foam or mesh, may be an electrostatic ionization filtration system that electrically charges the contaminants so that they are attracted to either a positively charged or negatively charged surface, or the air filters 80,82 may be a combination thereof or any other suitable air filtering system.

The apparatus 10 further comprises means for establishing and maintaining a magnetic field within the chamber 20 of a predetermined strength and orientation. As with other aspects of the apparatus and the closed ecological system created and maintained thereby, a magnetic field may also be established within chamber 28 although for reasons of clarity, reference will only be made to chamber 20. Referring to FIG. 7 wherein the apparatus 10 is shown schematically, a magnetic field coil 90 comprising shielded copper wire or the like surrounds and/or lines chamber 20 and is coupled by wires or the like to a D/D power generator 92 which generates controlled electromagnetic pulses (Hz) at optimal energy levels (Gauss). D/D power generator 92 is connected to a control mechanism such as control panel 94 which may be an analog device or a digital computer allowing a machine operator to vary the strength and orientation of the magnetic field created by the magnetic field coil 90 by varying the magnitude and direction of the electric current flowing through magnetic field coil 90.

It is thought preferable to establish and maintain a magnetic field within chamber 20 of 0.5 Hz to 30 Hz at 1-5 Gauss and is thought most preferable to average a magnetic field of 8 Hz within chamber 20. A variable magnetic field of 8 Hz (average, with intensity nearing 5 Gauss) is thought to simulate the magnetic field found on earth thousands of years ago. The magnetic field may be cyclical--i.e., turned on and off, or raised and lowered depending upon other aspects of the closed ecological system. For example, the magnetic field may be elevated only in the "day" or "night" as such terms are defined above. Alternatively or in conjunction with the "day and "night" variables, the magnetic field may be dependent upon the song activity of live birds present within the chamber 20 or dependent upon the sounds of birds that are broadcast within the chamber 20 through a sound system as is discussed in greater detail below.

FIG. 8 schematically illustrates a sound system 100 to be used in conjunction with the apparatus 10 of the present invention to establish predetermined sounds within the chamber 20. Sound system 100 comprises a power supply 102 which may be the same as power supply 21 discussed previously, or power supply 102 may be separate therefrom. Power supply 102 is connected to and provides electrical power to a sound control panel 104 from where one may control the selection and characteristics of the sounds broadcast by the sound system 100 into chamber 20. Control panel 104 is connected to one or more speakers 106 for broadcasting sound and is also connected to one or more microphones 108 for receiving sound from within chamber 20 and transmitting the same onto a recording medium or for broadcasting such sounds outside of chamber 20. Control panel 104 may be located either inside or outside of chamber 20 such that sound system 100 may be controlled by a person outside of chamber 20 or inside chamber 20, depending upon the location of control panel 104. It has been found beneficial for animals and plants to be within chamber 20 while sound from sound system 100 is broadcast into chamber 20. For example, harmonic music corresponding to songs of birds within chamber 20 at controlled times and under controlled conditions has been found to be particularly beneficial to plants and animals within chamber 20. By broadcasting the songs of birds where the songs are tuned to a frequency of 256 Hz ranging from 2-60 decibels in intensity, the sounds of the harmonic music will be tuned to the antenna of the DNA and cellular structure of the cells of animals which thereby causes a resonance of such cells and alters the vibratory cycle of the cells, leading to the improved health thereof, and leading to the deterioration of abnormal cells. As an alternative to broadcasting songs of birds into chamber 20, symphonic music, broadcast into chamber 20 in accordance with the above-noted broadcast parameters, may alternatively be utilized with the same or similar therapeutic effects.

As mentioned previously, the apparatus 10 allows for the creation of a closed ecological system in accordance with the above, thereby creating an environment conducive to the manufacture of exceptional pharmaceuticals for treating diseases and ailments for which safe and effective pharmaceuticals have not yet been discovered. Such exceptional pharmaceuticals may be obtained through natural organic production of living systems themselves or may be obtained by mixing various chemicals. For example, referring now to FIGS. 9 and 10, there can be seen a scanning electron microscope view of snake venom obtained from a Copperhead snake living under ordinary conditions found on earth (FIG. 9) and a scanning electron microscope view of snake venom obtained from the same snake, after the snake lived in an apparatus 10 housing a closed ecological system as is set forth above. Those skilled in the art will recognize the markedly improved characteristics of the venom shown in FIG. 10 obtained from the Copperhead snake that inhabited the closed ecological system of the present apparatus 10 for four weeks. Snake venom shown in FIG. 10 has been experimented with and found to have medicinal properties such as decreasing the size and occurrence of cancerous tumors, and providing relief from emotional illnesses. It is theorized that the toxicity of snake venom in the present invention would be lowered, if not eliminated, and the coherent structured chemical formation as shown would lead to immediate assimilation into patient receptors.

Those skilled in the art will recognize that the apparatus 10 may further comprise conveniences and necessaries to sustain life such as water nutrients, waste facilities and the like. Also, while the foregoing description has set forth the preferred embodiment of the invention in particular detail, it must be understood that numerous modifications, substitutions, and changes may be undertaken without departing from the true spirit and scope of the present invention as defined by the ensuing claims.

METHOD AND APPARATUS TO STIMULATE THE IMMUNE SYSTEM OF A BIOLOGICAL ENTITY

US7338431

A system and method for stimulating the immune systems of biological entities in an environment. Pulsed electrical currents are generated using an electric current generator. The pulsed electrical currents are fed through an arrangement of electrically conductive material such that magnetic energy is emitted from the arrangement into the environment. The arrangement of electrically conductive material is designed such that an intensity of the emitted magnetic energy varies across at least one spatial dimension of the environment. Certain embodiments of the arrangement, which have width-to-length ratios of approximately 0.6, tend to provide variations in the intensity of the magnetic energy field which are very good for stimulating the immune systems of the biological entities.

TECHNICAL FIELD

Certain embodiments of the present invention relate to stimulating the immune system of biological entities. More particularly, certain embodiments of the present invention relate to a system and method to stimulate the immune system of biological entities moving in an environment through application of pulsed magnetic energy.

BACKGROUND OF THE INVENTION

Use of magnetic energy to increase physiological performance of organisms has long been attempted. However, many of these techniques have been limited to belts, pads or mats which apply magnetic or electromagnetic energy to the person or other organism. Problems inherent in these techniques include the necessity for the organism to wear the belt or pad, and the necessity for a portable power source in order to generate magnetic energy. Furthermore, these techniques do not effect the environment surrounding the organism. Accordingly, there is a demand for an apparatus and method of applying pulsed magnetic energy to an organism (i.e., a biological entity) and its surrounding environment that is without the aforementioned disadvantages.

Further limitations and disadvantages of conventional, traditional, and proposed approaches will become apparent to one of skill in the art, through comparison of such systems and methods with the present invention as set forth in the remainder of the present application with reference to the drawings.

BRIEF SUMMARY OF THE INVENTION

An embodiment of the present invention comprises a system for stimulating immune systems of living biological entities in an environment. The system comprises at least one electric current generator providing a source of pulsed electrical current. The system further comprises at least one continuous coil of electrically conductive material having a first end and a second end, both of the ends being connected to the at least one generator to form a closed circuit such that the at least one coil emits a spatially non-uniform pulsed magnetic field into the environment in response to the pulsed electrical current to stimulate the immune systems as the biological entities move within the environment. Also, a configuration of the at least one coil comprises a plurality of turns of the conductive material in substantially a single spatial plane, and wherein the coil has an overall width-to-length ratio of between 0.4 and 0.8.

Another embodiment of the present invention comprises a system for stimulating immune systems of biological entities in an environment. The system comprises at least one electric current generator providing a source of pulsed electrical current. The system further comprises at least one arrangement of electrically conductive material having a first end and a second end, both of the ends being connected to the at least one generator to form a closed circuit such that the at least one arrangement emits a spatially non-uniform pulsed magnetic field into the environment in response to the pulsed electrical current to stimulate the immune systems as the biological entities move within the environment. Also, a configuration of the at least one arrangement comprises a plurality of substantially parallel segments of the conductive material forming a flat, substantially rectangular grid having an overall width-to-length ratio of between 0.4 and 0.8.

A further embodiment of the present invention comprises a method for stimulating immune systems of living biological entities in an environment. The method comprises positioning at least one arrangement of electrically conductive material below a surface of the environment and connecting the at least one arrangement of electrically conductive material to at least one electric current generator to form a closed circuit through the arrangement. The method further comprises generating a pulsed electrical current with the generator such that the pulsed electrical current propagates through the arrangement from a first end of the arrangement to a second end of the arrangement. The arrangement emits pulsed magnetic energy into the environment in response to the pulsed electrical current such that an intensity of the pulsed magnetic energy is non-uniform across at least one spatial dimension of the arrangement to stimulate the immune systems as the biological entities move within the environment.

Another embodiment of the present invention includes a system for stimulating the immune systems of biological entities in an environment. The system comprises at least one electric current generator providing a source of pulsed electrical current. The system further comprises at least one continuous coil of electrically conductive material having a first end and a second end where both ends are connected to the generator to form a closed circuit such that the coil emits a spatially non-uniform pulsed magnetic field into the environment in response to the pulsed electrical current to stimulate the immune systems as the biological entities move within the environment. A configuration of the coil includes a plurality of parallel straight segments of the conductive material, being substantially of the same length, and a plurality of curved segments of the conductive material. The continuous coil spirals outward from a central position of the coil in substantially a single spatial plane.

A further embodiment of the present invention includes a system for stimulating the immune systems of biological entities in an environment. The system comprises at least one electric current generator providing a source of pulsed electrical current. The system further comprises at least one continuous coil of electrically conductive material having a first end and a second end where both ends are connected to the generator to form a closed circuit such that the coil emits a spatially non-uniform pulsed magnetic field into the environment in response to the pulsed electrical current to stimulate the immune systems as the biological entities move within the environment. A configuration of the coil comprises a first plurality of parallel straight segments of the conductive material and a second plurality of parallel straight segments of the conductive material being substantially perpendicular to the first plurality of segments. The continuous coil winds outward from a central position of the coil in substantially a single spatial plane.

These and other advantages and novel features of the present invention, as well as details of illustrated embodiments thereof, will be more fully understood from the following description and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a first exemplary embodiment of a system for applying pulsed magnetic energy to an aquatic environment, in accordance with various aspects of the present invention.

FIG. 2 illustrates a first exemplary embodiment of a flat coil used to generate magnetic energy, in accordance with various aspects of the present invention.

FIGS. 3A-3C illustrate various views of an embodiment of the flat coil of FIG. 2, clearly showing the spacing between the coil turns, in accordance with various aspects of the present invention.

FIG. 4 illustrates an exemplary simulated graph of how a magnetic field intensity generated by the coil of FIG. 2 may be expected to vary non-linearly across a spatial dimension of the coil of FIG. 2, in accordance with various aspects of the present invention.

FIG. 5 illustrates an exemplary graph of measured data of how a magnetic field intensity generated by the coil of FIGS. 3A-3C varies across three spatial dimensions of the coil of FIGS. 3A-3C, in accordance with various aspects of the present invention.

FIG. 6 is a flowchart of an embodiment of a method to stimulate immune systems of biological entities in an environment, in accordance with various aspects of the present invention.

FIG. 7 illustrates a second exemplary embodiment of a flat coil used to generate magnetic energy, in accordance with various aspects of the present invention.

FIG. 8 illustrates a second exemplary embodiment of a system for applying pulsed magnetic energy to a stock pen environment, in accordance with various aspects of the present invention.

FIG. 9 illustrates a third exemplary embodiment of a system for applying pulsed magnetic energy to a garden environment, in accordance with various aspects of the present invention.

FIG. 10 illustrates a fourth exemplary embodiment of a system for applying pulsed magnetic energy to a sports environment, in accordance with various aspects of the present invention.

FIG. 11 illustrates a fifth exemplary embodiment of a system for applying pulsed magnetic energy to a golf course environment, in accordance with various aspects of the present invention.

FIG. 12 illustrates exemplary resultant current pulses that may be produced in the coil of FIG. 2 when applying an exemplary DC pulsed voltage waveform to the coil of FIG. 2, in accordance with an embodiment of the present invention.

FIG. 13 illustrates exemplary resultant current pulses produced in the coil of FIGS. 3A-3C when applying an exemplary DC pulsed voltage waveform to the coil of FIGS. 3A-3C, in accordance with an embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Reference will now be made in detail to the various embodiments of the present invention, examples of which are illustrated in the accompanying drawings. Whenever possible, the same reference numbers will be used throughout the drawings to refer to the same or like parts.

FIG. 1 illustrates a first exemplary embodiment of a system for applying pulsed magnetic energy to an aquatic environment, in accordance with various aspects of the present invention. Shown generally at 10, the embodiment of FIG. 1 includes a water reservoir 12, such as an aquarium, a pool, a pond or some other body of water. Below water reservoir 12 is placed electric wiring 16. In FIG. 1 electric wiring 16 is shown as a continuous coil of wiring, originating from the electric current generator 14 at a first end 17 and connecting back to the electric current generator 14 at a second end 19 to form a closed circuit. The electrical wiring 16 is placed over a substantial area of the water reservoir 12, at 1 to 30 inches below the bottom surface of the water reservoir 12, and is insulated from the surrounding elements and cross currents from other cables that may be present. If the water reservoir 12 has sides, such as in a pool, electric wiring 16 can also be placed behind the surface of the sides of reservoir 12. Electric wiring 16 is insulated by neutral materials, such as plastics, that will insulate the electric wiring 16, yet not produce a significant charge in the surrounding soil or substance. The electric wiring may be coated with an insulating material or may be placed in a non-conductive conduit, for example. Further, highly shielded electrical wire (e.g., using a conductive shield) is not desired as it decreases the capacity of diffusion of the pulsed magnetic energy into the aquatic environment. A pulsed DC voltage waveform is supplied to the electric wiring 16, and is controlled by the electric current generator 14. Pulsed current supplied by the generator 14 propagates from a first end 17 of the coil 16 to a second end 19 of the coil 16 in a closed loop in response to the pulsed DC voltage waveform. That is, both ends 17 and 19 of the coil 16 are connected to output terminals of the generator 14. Alternatively, pulsed current supplied by the generator 14 may propagate from the second end 19 to the first end 17.

Optionally, an air pump 18 and perforated air hose 20 may be included in the system embodied in FIG. 1. Air pump 18 and air hose 20 provide an oxygen source to the water within reservoir 12, thus, aerating the water and increasing the oxygen concentration of the water.

In use, pulsed electrical current is applied to the electric wiring 16 by an electric current generator 14. Various electronic components may be utilized to generate electric current for use in this system and may include a computer controlled subsystem, for example, to control the intensity and pulsed frequency of the emitted magnetic energy. An electric current generator typically includes a power transformer, a rectifier and filter circuit, and an electronic switching circuit. For example, an electric current generator may be plugged into a 240 VAC single phase power source and output a pulsed DC voltage waveform having a maximum peak amplitude of, for example, 80 VDC.

In accordance with an embodiment of the present invention, the magnetic energy emitted from the wiring 16 has magnetic field components in the range of about 0.5 to 30 Gauss, and the frequency range of the pulses is between 0.5 and 30 Hertz. Concurrently, air pump 18 pumps air through hose 20 to increase the oxygen concentration of the water. The water in free motion around the air bubbles is energized to a higher state because of the application of the pulsed magnetic energy, and thus may become even more saturated with oxygen.

Application of the magnetic energy to the reservoir 12 provides for application of magnetic energy to both plants and animals (i.e., biological entities) situated within the aquatic system. The affected plants and animals exhibit enhanced physiologic effects such as increased growth and overall health, for example, due to stimulation of the immune systems of the plants and animals. Furthermore, the highly oxygenated and energized water can then be utilized for watering plants which may not be directly exposed to the magnetic energy.

Electric current flows in a wire when a potential difference (i.e., a voltage) is applied across both ends of the wire. When electric current flows through a wire, a magnetic field is set up or emanates from the wire. If the wire is arranged in a coiled or grid-like configuration, for example, the magnetic fields from the various turns of the coil may combine constructively and destructively to form a spatially non-uniform magnetic field profile.

FIG. 2 illustrates an exemplary embodiment of a flat coil 200 used to generate magnetic energy, in accordance with various aspects of the present invention. The coil is a continuous coil of electrically conductive material (e.g., copper wire) having a first end 201 and a second end 202. Both ends 201 and 202 are connected to at least one generator (e.g. generator 14 in FIG. 1) to form a closed circuit. The generator creates a pulsed voltage waveform (e.g., a DC pulsed waveform) that results in pulsed electrical currents that propagate through the coil 200 from the first end 201 to the second end 202 (or vice versa). When the current pulses propagate through the coil 200, magnetic energy is emitted from the coil in the form of a pulsed magnetic field. When the coil is placed in an environment such as, for example, a swimming pool, a livestock yard, a garden, orchards, an athletic ground, a play ground, a pond, a lake, a whirl pool, a hot tub, or an aquarium, the magnetic energy is dispersed into the environment. The magnetic energy tends to stimulate the immune systems of biological entities (e.g., plants, animals, and humans) that are moving within the environment.

In accordance with an embodiment of the present invention, a configuration of the coil 200 comprises a plurality of spiraling turns of a conductive material such as, for example, copper wire. The spiraling turns do not necessarily follow a strictly mathematical spiral, but rather, the turns spiral at least in the sense that the turns wrap around on each other from the inside (i.e., from a central position 203 of the coil 200) to the outside of the coil 200. The configuration forms a flat, substantially oval surface having a width-to-length ratio of between 0.4 and 0.8. Ideally, the width-to-length ratio is 0.618 which is the "golden mean" ratio found in many instances of nature. For example, the width-to-length ratio of the coil 200 shown in FIG. 2 is 84.1232 inches divided by 156 inches which is a ratio of 0.539. The coil 200 of FIG. 2 has approximately 37 turns spaced at approximately 1 inch separation. In accordance with an embodiment of the present invention, the coil 200 comprises 8 Gage solid copper wire having a resistance of about 0.6 ohms per 1000 feet.

The configuration of the coil 200 includes a plurality of parallel straight segments 210 of insulated copper wire being of substantially the same length, and a plurality of curved segment of insulated copper wire 220. The segments 210 and 220 are not discrete in the sense that they must be connected to form the coil 200. Instead, the coil 200 is a continuous piece of copper wire. However, in an alternative embodiment the coil 200 could be made from discrete segments that are connected together by, for example, welding or soldering. The configuration of the coil 200 is such that the plurality of turns of the coil are substantially in a single spatial plane, which gives the coil 200 its flat shape.

In accordance with the embodiment of FIG. 2, the coil emits a magnetic field at least perpendicular to the surface of the coil (i.e., out of the page of FIG. 2). The intensity of the magnetic field varies (i.e., is non-uniform) across the coil 200, in a spatial dimension which is parallel to the surface of the coil 200. The variation may be non-linear, in accordance with certain embodiments of the present invention. Therefore, as a biological entity moves within the environment in which the coil 200 is placed, the biological entity experiences the variations of the magnetic field. The variations stimulate the immune system of the biological entity. Typically, the coil 200 is insulated using a non-conducting material such as a plastic, to prevent direct conduction of the electrical currents into the surrounding environment.

FIGS. 3A-3C illustrate various views of an embodiment of the flat coil 200 of FIG. 2, clearly showing the spacing between the coil turns, in accordance with various aspects of the present invention. The coil 200 shown in FIG. 3A is mounted on a surface 310 (e.g., a plywood board) using plastic clips to secure the wiring of the coil 200.

FIG. 3B shows a curved section of the coil 200 with the spacing 320 between the curved segments being about one inch. FIG. 3C shows a straight section of the coil 200 with the spacing 330 between the straight and parallel segments being about one inch.

FIG. 4 illustrates an exemplary simulated graph 400 of how a magnetic field intensity Bm 401 generated by the coil 200 of FIG. 2 may be expected to vary non-linearly across a spatial dimension 402 of the coil of FIG. 2 (distance across coil), in accordance with various aspects of the present invention. The peak magnetic intensity 403 occurs at the center of the coil 200. It is the configuration of the coil (e.g., shape, dimensions, spacing) that largely determines the shape of the spatially non-uniform magnetic field intensity. For example, the graph 400 of FIG. 4 may represent the variation in magnetic field intensity Bm across the width dimension 240 of the coil 200 and through a first center axis 250 of the coil 200 (see FIG. 2).

FIG. 5 illustrates an exemplary graph 500 of measured data of how a magnetic field intensity 501 generated by the coil 200 of FIGS. 3A-3C varies across three spatial dimensions of the coil 200 of FIGS. 3A-3C, in accordance with various aspects of the present invention. The data set 510 shows the variation in measured magnetic field intensity above (e.g., 18 inches) the coil 200 and across the length dimension 260 of the coil 200 along the axis 265 which includes the physical center point 205 of the coil 200 (see FIG. 2). The coil center 540 is shown on the distance axis 550 in FIG. 5.

The data set 520 shows the variation in measured magnetic field intensity above (e.g., 18 inches) above

the coil 200 and across the width dimension 240 of the coil 200 along the axis 250 which includes the physical center point 205 of the coil 200. The data set 530 shows the variation in measured magnetic field intensity above (e.g., 18 inches) the coil 200 and across a diagonal dimension of the coil 200 along the axis 270 which includes the physical center 205 of the coil 200.
The direction of the magnetic field intensities 510, 520, and 530 shown in the graph 500 is perpendicular to the flat surface of the coil 200. The absolute magnitude of the magnetic field intensities is a function of distance away from the surface or plane of the coil. In general, the magnetic field intensity decreases at points further away from the surface or plane of the coil. Notice that the magnetic field intensity 560 at the physical center of the coil is the same for all three data sets 510, 520, and 530 since the center corresponds to the same physical point in all three cases.

For example, if the coil 200 is placed flat and just beneath the bottom surface of a swimming pool (e.g., 1 to 30 inches), the magnetic field intensity 501 of the data sets 510, 520, and 530 will emanate above the coil into the water of the pool. As a swimmer swims through the pool across the coil (e.g., parallel to the surface of the coil), the swimmer will experience the magnetic variations of the magnetic field generated by the coil which stimulate the swimmer's immune system. In accordance with an embodiment of the present invention, the magnetic field is a pulsed magnetic field having a pulsed frequency of between 0.5 and 30 Hertz, and the intensity of the magnetic fields 510, 520, and 530 at a predetermined distance from the surface of the coil (e.g., 18 inches) vary through a range of about 0.5 to 30 Gauss across at least one spatial dimension of the coil 200. The electric current generator may comprise a programmable subsystem (e.g., a programmable logic controller or a computer-based subsystem such as a personal computer) which may control the frequency and intensity of the current pulses and, therefore, of the magnetic energy pulses.

FIG. 6 is a flowchart of an embodiment of a method 600 to stimulate immune systems of biological entities in an environment, in accordance with various aspects of the present invention. In step 610, at least one arrangement of electrically conductive material is positioned below a surface of an environment (for example, referring to FIG. 1, the coil 16 is positioned below the surface of the aquatic environment 12). In step 620, the at least one arrangement of electrically conductive material is connected to at least one electric current generator to form a closed circuit through the arrangement (for example, referring to FIG. 1, the ends 17 and 19 of the coil 16 are connected to electric terminals of the generator 14). In step 630, a pulsed electrical current is generated with the generator such that the pulsed electrical current propagates through the arrangement from a first end (e.g., end 19 in FIG. 1) of the arrangement to a second end (e.g., end 17 in FIG. 1) of the arrangement, and wherein the arrangement emits pulsed magnetic energy into the environment in response to the pulsed electrical current such that an intensity of the pulsed magnetic energy is non-uniform across at least one spatial dimension of the arrangement (e.g., see the non-uniform magnetic fields of FIGS. 4 and 5) to stimulate the immune systems as the biological entities move within the environment.

FIG. 7 illustrates a second exemplary embodiment of a flat coil 700 used to generate magnetic energy, in accordance with various aspects of the present invention. The coil 700 has a first end 701 and a second end 702 and comprises a first plurality of vertically oriented, parallel straight segments 710 of conductive wire and a second plurality 720 of horizontally oriented, parallel straight segments 720 of conductive wire which are substantially perpendicular to the first plurality of segments. The coil 700 is a continuous wire, winding outward from a central position 730 of the coil 700 in substantially a single spatial plane forming a flat, rectangular coil (i.e., a coil forming a flat, rectangular surface). The coil 700 of FIG. 7 is similar to the coil 200 of FIG. 2 except the curved segments of FIG. 2 are replaced with the straight segments 720 of FIG. 7 and the straight segments 710 are not all of the same length.

Referring now to FIG. 8, there is shown a second exemplary embodiment a system of the present invention, illustrating the application of pulsed magnetic energy to livestock animal pens. In this second embodiment, there is a stock pen 830 which can be used to retain any type of livestock animal or poultry. Further, it should be understood that such a stock pen can be enclosed in buildings or open fields. Electrical wiring 820 extends below the surface and laterally across first stock pen 830 to cover at least a substantial area of stock pen 830. The configuration of the electrical wiring 820 includes a plurality of substantially parallel segments of conductive material (e.g., segments of wiring) forming a flat, substantially rectangular grid. As in the first embodiment 10 of FIG. 1, electrical wiring 820 is comprised of electrical wiring having neutral insulating materials, and is placed under the surface of the selected area at a preferred depth of 1 to 30 inches. Electric current generator 810 generates and transmits pulsed electric currents through electric wiring 820. In accordance with an embodiment of the present invention, the width-to-length ratio of the substantially rectangular grid is between 0.4 and 0.8.

Optionally, this system may also include a water tank 840 for the watering of the animals. An air pump 850 may be used to pump air into the water tank 840 through hose 860. Aeration of water tank 840 by pump 850 increases the oxygen concentration of the water held within water tank 840.

In the embodiment of FIG. 8, the electrical wiring 820 forms a type of horizontal grid configuration across the stock pen 830. Pulsed current flows from the generator 810 through the various branches of the grid of wiring 820 and back to the generator 810, emitting pulsed magnetic energy (i.e., magnetic fields) into the environment of the stock pen 830. If the stockyard is enclosed, the electric wiring is buried at a depth between 1 and 30 inches within the dirt or other flooring material, such as concrete, for example. Again, a spatially non-uniform magnetic field is generated across the grid. However, the non-uniformity may be substantially different from that shown in FIGS. 4 and 5 due largely to the different configuration of the wiring 820 from that of the coil 200 of FIG. 2. However, a coil of the configuration of that of FIG. 1 or FIG. 2, or other configurations, could be used in the stockyard environment instead.

Now referring to FIG. 9, there is shown a third exemplary embodiment of a system of the present invention illustrating the application of pulsed magnetic energy to a plant bio-system 900, such as a garden. The plant based bio-system may include, for example, a grain plot 910, fruit or other trees 920, plants 930 and/or flowers 940. The plants may either be grown within the ground itself or within planting containers such as pots and the like. The environment 900 may optionally also include a water reservoir 950, which is aerated by hose 960 and air pump 970 to increase the oxygen concentration of the water held within reservoir 950. Pulsed magnetic energy is generated by an electric current generator 980 applying pulsed currents to electric wiring grid 990. Electric wiring grid 990 is positioned to cover at least a substantial portion of environment 900, and is placed below the surface of environment 900, at a depth of 1 to 30 inches. The plants affected by the application of the pulsed magnetic energy exhibit improved physiological effects such as improved and more rapid growth, and better overall health for example.

Shown in FIG. 10 is yet another exemplary embodiment of the present invention, illustrating applying magnetic energy to an athletic playing surface 1000, such as, for example a basketball court, a football field, a soccer field, a swimming pool, playgrounds or other playing surfaces. Electrical wiring 1010 is placed below playing surface 1000 at a preferred depth of between 1 and 30 inches. Electrical current generator 1020 generates and conducts electrical currents through electric wiring 1010 to create and diffuse the resultant magnetic energy throughout playing surface 1000. The magnetic energy is applied to those persons playing or competing on playing surface 1000. Upon application of the magnetic energy, humans may experience higher energy levels for longer periods of time, reduced fatigue, less muscle strain and soreness, in addition to increased concentration and precision in playing the particular sport.

Referring now to FIG. 11, there is shown yet another exemplary embodiment of the present invention, illustrating application of magnetic energy to a golf course hole. This embodiment includes a tee box 1110, a green 1120 and/or optionally a water reservoir 1130. Below tee box 1110 is placed electrical wiring 1140, which is placed at a depth of 1 to 30 inches. Electrical wiring 1150 is also placed below golf green 1120 at a preferred depth of 1 to 30 inches. If water reservoir 1130 is used, electrical wiring 1160 is positioned below the bottom of reservoir 1130 at a depth of 1 to 30 inches for emission of magnetic energy. Air pump 1195 and air hose 1196may optionally be used to pump air into the water reservoir 1130 to increase the oxygen content. Treated water from reservoir 1130 may be used to water the golf course fairways, greens, or other plants associated with the course as to achieve the benefits as described above in relation to the plant based bio-system embodiment. Electric current generators 1170, 1180 and 1190 produce pulsed electric currents such that magnetic energy is emitted from electrical wiring 1140, 1160, and 1150 respectively. Optionally, a single generator can control the emission of magnetic energy from electrical wiring 1140, 1160, and 1150. As with the above described embodiments, electric current generators 1170, 1180 and 1190 cause magnetic energy to be emitted having magnetic field components about in the range of 0.5 to 30 Gauss, and the frequency range of the pulses is between 0.5 and 30 Hertz.

Effects seen through application of the pulsed magnetic energy to a grass surfaces such as soccer fields, play grounds, football fields, golf greens and tee boxes include more rapid and healthier growth of grass, faster regeneration or repair of divots and ball marks, fewer attacks to these grasses by pests as the grasses are healthier. The human players experience gentle invigoration, increased energy, greater concentration, and less muscle soreness or strain. Increased mental activity and faster healing of wounds has also been noted. Sporting equipment such as golf clubs are not affected by the application of magnetic energy because no sustained electrical current is conducted to the metal portions of the clubs.

In use with any of the above embodiments, the characteristics of the magnetic energy remain the same, that is the magnetic energy having magnetic field components about in the range of 0.5 to 30 Gauss, and the frequency range of the pulses between 0.5 and 30 Hertz. In application of pulsed magnetic energy to humans, the magnetic field strength may be adjusted to vary between 4 to 8 Gauss. The placement of the electrical wiring below the surface of the selected area is adjusted to accommodate these parameters. Further, it is important to note that the spacing and arrangement of the electric wiring in the above described embodiments may be altered to achieve certain desired effects.

FIG. 12 illustrates exemplary resultant current pulses 1210 and 1220 that may be produced in the coil 200 of FIG. 2 when applying an exemplary DC pulsed voltage waveform 1230 to the coil 200 of FIG. 2, in accordance with an embodiment of the present invention. The pulsed voltage waveform 1230 shown in FIG. 12 is a square voltage waveform having a 50% duty cycle. Other duty cycles are possible as well, in accordance with various embodiments of the present invention. The pulsed voltage waveform 1230 is applied to the coil 200 by a generator (e.g., generator 14 of FIG. 1).

The frequency of the pulsed voltage waveform 1230 may be, for example, anywhere between 0.1 Hz and 30 Hz. Depending on the various parameters (e.g., the voltage level, the time constant, the pulsed frequency, etc.) of the system, the resultant pulsed current waveform in the coil may look like that of waveform 1210. Referring to the pulsed current waveform 1210, as the voltage level of the pulsed voltage waveform 1230 increases, the current level in the coil will begin to increase as seen in the segment 1211 of the pulsed current waveform 1210. The curved nature of the rising current level of the segment 1211 is due, at least in part, to the time constant of the system (including the coil) which is determined by inductive, capacitive, and resistive factors of the system. In the pulsed current waveform 1210, the current level rises continuously until the voltage level of the driving pulsed voltage waveform drops off.

When the voltage level of the pulsed voltage waveform 1230 decreases, the current level in the coil will begin to decrease as seen in the segment 1212 of the pulsed current waveform 1210. Again, the curved nature of the falling current level of the segment 1212 is due, at least in part, to the time constant of the system. In the pulsed current waveform 1210, the current level decreases continuously until the voltage level of the driving pulsed voltage waveform again rises. For example, the peak voltage level of the DC pulsed voltage waveform 1230 may be 80 VDC and the resultant peak current level of the pulsed current waveform 1210 may be 100 amps.

Referring to the pulsed current waveform 1220, as the voltage level of the pulsed voltage waveform 1230 increases, the current level in the coil will begin to increase as seen in the segment 1221 of the pulsed current waveform 1220. Again, the curved nature of the rising current level of the segment 1221 is due, at least in part, to the time constant of the system. In the pulsed current waveform 1220, the current level rises and then flattens off to a peak current level 1222 well before the voltage level of the pulsed voltage waveform drops off. This flattening off tends to occur when the peak voltage level 1231 is relatively low. The lower peak voltage level 1231 means that the current will not build to as high a level as it would with a higher peak voltage level driving the coil. Therefore, the pulsed current waveform 1220 reaches its peak level sooner and stays there.

When the voltage level of the pulsed voltage waveform 1230 decreases, the current level in the coil will begin to decrease as seen in the segment 1223 of the pulsed current waveform 1220. Again, the curved nature of the falling current level of the segment 1223 is due, at least in part, to the time constant of the system. In the pulsed current waveform 1220, the current level decreases to a zero current level 1224 well before the voltage level of the pulsed voltage waveform increases again. Again, this flattening off tends to occur when the peak voltage level 1231 is relatively low. That is, the current level does not have as far to fall since the peak current level was relatively low. Therefore, the current level reaches zero sooner and flattens off. For example, the peak voltage level of the DC pulsed voltage waveform 1230 may be 20 VDC and the resultant peak current level of the pulsed current waveform 1210 may be 10 amps.

FIG. 13 illustrates exemplary resultant current pulses 1310 produced in the coil 200 of FIGS. 3A-3C when applying an exemplary DC pulsed voltage waveform 1320 to the coil 200 of FIGS. 3A-3C, in accordance with an embodiment of the present invention. The pulsed voltage waveform 1320 shown in FIG. 13 is a pseudo-square voltage waveform having a 50% duty cycle. Other duty cycles are possible as well, in accordance with various embodiments of the present invention. The pulsed voltage waveform 1320 tends to droop over the segment 1330 due to the load the coil provides to the generator. Therefore, the pulsed voltage waveform 1320 is not perfectly square.

The frequency of the pulsed voltage waveform 1320 may be, for example, anywhere between 0.1 Hz and 30 Hz. Depending on the various parameters (e.g., the voltage level, the time constant, the pulsed frequency, etc.) of the system, the resultant pulsed current waveform in the coil may look like that of waveform 1310. Referring to the pulsed current waveform 1310, as the voltage level of the pulsed voltage waveform 1320 increases, the current level in the coil will begin to increase as seen in the segment 1311 of the pulsed current waveform 1310. The curved nature of the rising current level of the segment 1311 is due, at least in part, to the time constant of the system (including the coil) which is determined by inductive, capacitive, and resistive factors of the system. In the pulsed current waveform 1310, the current level rises continuously until the voltage level of the driving pulsed voltage waveform begins to droop. There is a time delay, however, between when the voltage level begins to droop and when the current level begins to decrease slightly over the segment 1312.

When the voltage level of the pulsed voltage waveform 1320 drops off, the current level in the coil will begin to decrease as seen in the segment 1313 of the pulsed current waveform 1310. Again, the curved nature of the falling current level of the segment 1313 is due, at least in part, to the time constant of the system. In the pulsed current waveform 1310, the current level decreases continuously until the voltage level of the driving pulsed voltage waveform again rises.

In accordance with various embodiments of the present invention, the systems described herein may be used by incrementing and/or decrementing the pulsed frequency over time. For example, in accordance with an embodiment of the present invention, the pulsed frequency may start at 0.5 Hz and be incremented every one minute by 0.5 Hz until reaching 28 Hz. Then the pulsed frequency may be decremented from 28 Hz back down to 0.5 Hz at a frequency step of 0.5 Hz every minute. Other methods of varying the pulsed frequency over time are possible as well and may be tailored to certain physiological conditions to be treated by stimulating the immune system.

In summary, a method and systems are disclosed for stimulating the immune systems of biological entities in an environment. A magnetic energy field is generated such that the magnetic energy field varies non-uniformly in intensity across at least one spatial dimension of the environment. The magnetic energy field is generated using an electric current generator which is connected to a coil or other alternate arrangement of conductive material such as wire. The coil or arrangement is typically placed beneath a surface of the environment. The magnetic energy field is pulsed at a predetermined frequency.

While the invention has been described with reference to certain embodiments, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted without departing from the scope of the invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the invention without departing from its scope. Therefore, it is intended that the invention not be limited to the particular embodiment disclosed, but that the invention will include all embodiments falling within the scope of the appended claims.

ELECTROMAGNETIC ENERGY ENHANCING GROWTH AND BIOLOGICAL FUNCTION

WO2005084746

A system (14,16,18,20) and method of enhancing growth and biological functions of living systems through application of pulsed electromagnetic energy. An Electromagnetic generator (14) connected to electrical wiring (16) wich is placed below the surface of a selected area such as, a garden, stock pen or athletic playing field (24) for emission of electromagnetic energy to plants and animals, including humans.

FIELD OF THE INVENTION

The present invention is generally a means to enhance growth and performance of biological systems. More specifically, the present invention is a system and method to enhance physiological performance of organisms through application of pulsed electromagnetic energy.

BACKGROUND OF THE INVENTION

Use of electromagnetic energy to increase physiological performance of organisms has long been attempted. However, many of these techniques have been limited to belts, pads or mats which apply magnetic or electromagnetic energy to the person or other organism. Problems inherent in these techniques include the necessity for the organism to wear the belt or pad, and the necessity for a portable power source in order to generate electromagnetic energy.

Furthermore, these techniques do not effect the environment surrounding the organism, nor do they bring the environment and organism into gentle resonance. Accordingly, there is a demand for an apparatus and method of applying pulsed electromagnetic energy to an organism and its surrounding environment that is without the aforementioned disadvantages.

SUMMARY OF THE INVENTION

The present invention is an apparatus and method of applying pulsed electromagnetic energy to organisms such as humans or other animals, and to the organism's surrounding environment such as grass and other organisms within this environment. Specifically, electrical wiring which emits pulsed electromagnetic energy, is placed under the surface of the area in which the humans or other organisms are situated. This includes putting wiring in proximity to or under the surface of a variety of environments, such as livestock pens, poultry pens, ponds, garden plots, athletic courts, and golf courses. The system and method of the present invention is used in association with various different organisms or living systems such as humans and other animals, as well as plants, for example.

Electromagnetic energy is then pulsed through the electric wiring and diffused throughout the area surrounding the wiring, including the atmosphere above the surface of the selected area.

As the electromagnetic energy diffuses, it is applied to both the plants and animals within the selected area. The application of the pulsed electromagnetic energy brings these organisms into gentle resonance and enhances biological function and genetic expression of these organisms.

Generally, better health, increased appetite and higher consumption of water, are among the positive effects that have been experienced by participating humans.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic diagram of a first preferred embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to an aquatic bio-system.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Reference will now be made in detail to the present preferred embodiments of the present invention, examples of which are illustrated in the accompanying drawings.

Whenever possible, the same reference numbers will be used throughout the drawings to refer to the same or like parts.

Shown in Fig. 1 is a first preferred embodiment of the present invention. It illustrates the application of pulsed electromagnetic energy to any aquatic setting. Shown generally at 10, this embodiment includes a water reservoir 12, such as an aquarium, pool, pond or other body of water. Below water reservoir 12 is placed electric wiring 16. Although in Fig. 1 electric wiring 16 is shown in a continuous open ended coil of wiring, electric wiring 16 can be positioned in a discontinuous fashion having a main line and a plurality of other lines extending from the main line. The electrical wiring 16 is placed over a substantial area of water reservoir 12, from 1 to 30 inches below the bottom surface of the water reservoir 12 and is insulated from the surrounding elements and cross currents from other cables. If water reservoir 12 has sides, such as in a pool, electric wiring 16 can also be placed behind the surface of the sides of reservoir 12. Electric wiring 16 is insulated by neutral materials, such as plastics, that will insulate electric wiring 16, yet not produce a charge in the surrounding soil or substance. Further, highly shielded electrical wire is not desired as it decreases the capacity of diffusion of the pulsed electromagnetic energy. The pulsed electromagnetic energy is supplied to electric wiring 16, and is controlled by an electromagnetic energy generator 14.

Optionally, an air pump 18 and perforated air hose 20 may be included in the system embodied in Figure 1. Air pump 18 and air hose 20 provide an oxygen source to the water with in reservoir 12, thus, aerating the water and increasing the oxygen concentration of the water.

In use, pulsed electromagnetic energy is applied to the electric wiring 16 by an electromagnetic energy generator 14. Various electronic components maybe utilized to generate electromagnetic energy for use in this system, such as a computer system or a electromagnetic wave generator for example. Preferably, the electromagnetic energy has a magnetic field component in the range of 0.5 to 30 Gauss, and the frequency range of the pulses between 0.5 and 30 Hertz. Concurrently, air pump 18 pumps air through hose 20 to increase the oxygen concentration of the water. The water in free motion around the air bubbles is energized to a higher state because of the application of the pulsed electromagnetic energy, and thus becomes even more saturated with oxygen.

Application of the electromagnetic energy to reservoir 12 provides for application of electromagnetic energy to both plants and animals situated within the aquatic system. The affected plants and animals exhibit enhanced physiologic effects such as increased growth and overall health for example. Furthermore, the highly oxygenated and energized water can then be utilized for watering plants which are not directly exposed to electromagnetic energy.

Optionally the system and method of the present invention contemplates the sustained or intermittent introduction of acoustic energy into the aquatic setting or the environment of other embodiments of the present invention. Many forms of soothing sounds may provide enhanced benefit but most preferred is the use of symphonic music or sounds, preferably with minimal or no dischord. The introduction of such can be accomplished through a sound system 100 as is schematically illustrated in Fig. 6. Sound system 100 comprises a power supply 102, which may be independent or shared with other systems utilized in the environment, that is operably connected to a sound control panel 104 from which one may control the selection and characteristics of the sounds broadcast by sound system 100 into the surrounding environment of the present invention. Control panel 104 is connected to one or more speakers 106 for broadcasting the generated sound. In aquatic settings underwater speakers are contemplated.

Although not required, one or more microphones 108 for receiving sound from the aquatic setting or other environment is contemplated. Such sounds may be recorded as is known in the art.

Additionally the sustained or intermittent introduction of orgone or radionic energy into the aquatic setting of the environment or other embodiments of the present invention, especially but not necessarily in pulsed form, is contemplated. Such radionic energy is supplied through one or more radionic generators or collectors as are lcnown and available in the art. Exposure time and intensity may be varied.

Referring now to Fig. 2, there is shown a second embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to livestock animal pens. In this embodiment, there is a stock pen 24 which can be used to retain any type of livestock animal or poultry. Further, it should be understood that such a stock pen can be enclosed in buildings or open fields. Electrical wiring 26 extends below the surface and laterally across first stock pen 24 to cover at least a substantial area of stock pen 24. As in the first embodiment, electrical wiring 26 is comprised of electrical wiring having neutral insulating materials, and is placed under the surface of the selected area at a preferred depth of 1 to 30 inches. Electromagnetic energy generator 28 generates and transmits electromagnetic energy to electric wiring 26. Optionally, this system may also include a water tank 34 for watering of the animals. An air pump 30 may be utilized to pump air into the water tank 34 through hose 32. Aeration of water tank 34 by pump 30 increases the oxygen concentration of the water held within water tank 34.

If the stoclcyard is enclosed, the electric wiring is buried at a depth between 1 and 30 inches within the dirt or other flooring material, such as concrete, for example.

Now referring to Fig. 3, there is shown a third embodiment of the present invention illustrating the application of electromagnetic energy to a plant bio-system 46, such as a garden.

The plant based bio-system may include, for example, a grain plot 48, fruit or other trees 56, plants 58 and/or flowers 60. The plants may either be grown within the ground itself or within planting containers such as pots and the like. The system 46 may optionally also include a water reservoir 50, which is aerated by hose 52 and air pump 54 to increase the oxygen concentration of the water held within reservoir 50. Electromagnetic energy is generated by an electromagnetic energy generator 64 and applied to system 46 via electric wiring 62. Electric wiring 62 is position to cover at least a substantial portion of system 46, and is placed below the surface of system 46, at a depth of 1 to 30 inches. The plants affected by the application of the electromagnetic energy exhibit improved physiological effects such as improved and more rapid growth, and better overall health for example.

Shown in Fig. 4 is yet another embodiment of the present invention, illustrating applying electromagnetic energy to an athletic playing surface 68, such as, for example a basketball court, a football field, a soccer field, a swimming pool, playgrounds or other playing surfaces.

Electrical wiring 70 is placed below playing surface 68 at a preferred depth of between 1 and 30 inches. Electromagnetic energy generator 72 generates and conducts electromagnetic energy through electric wiring 70 to diffuse the electromagnetic energy throughout playing surface 68.

The electromagnetic energy is applied to those persons playing or competing on playing surface 68. Upon application of the electromagnetic energy, humans experience higher energy levels for longer periods of time, reduced fatigue, less muscle strain and soreness, in addition to increased concentration and precision in playing the particular sport.

Referring now to Fig. 5, there is shown yet another embodiment of the present invention, illustrating application of electromagnetic energy to a golf course hole. This embodiment includes a tee box 76, a green 92 and/or optionally a water reservoir 82. Below tee box 76 is placed electrical wiring 78, which is placed at a depth of 1 to 30 inches. Electrical wiring 94 is also placed below golf green 92 at a preferred depth of 1 to 30 inches. If water reservoir 82 is utilized, electrical wiring 88 is positioned below the bottom of reservoir 82 at a depth of 1 to 30 inches for emission of electromagnetic energy. Treated water from reservoir 82 may be used to water the golf course fairways, greens, or other plants associated with the course as to achieve the benefits as described above in relation to the plant based bio-system embodiment.

Electromagnetic energy generators 80,90 and 96 produce and emit electromagnetic energy through electrical wiring 78,88 and 94 respectively. Optionally, a single electromagnetic generator can control the emission of electromagnetic energy through electrical wiring 78,88 and 94. As with the above described embodiments, electromagnetic energy generators 80,90 and 96 emit electromagnetic energy having a magnetic field component in the range of 0.5 to 30 Gauss, and the frequency range of the pulses between 0.5 and 30 Hertz.

Effects seen through application of the electromagnetic energy to a grass surfaces such as soccer fields, play grounds, football fields, golf greens and tee boxes include more rapid and healthier growth of grass, faster regeneration or repair of divots and ball marks, fewer attacks to these grasses by pests as the grasses are healthier. The human players experience gentle invigoration, increased energy, greater concentration, and less muscle soreness or strain.

Increased mental activity and faster healing of wounds has also been noted.

Sporting equipment such as golf clubs are not affected by the application of electromagnetic energybecause no sustained electrical current is conducted to the metal portions of the clubs.

In use with any of the above embodiments, the characteristics of the electromagnetic energy remain the same, that is electromagnetic energy having a magnetic field component in the range of 0.5 to 30 Gauss, and the frequency range of the pulses between 0.5 and 30 Hertz. The cycling/hertz of the electromagnetic energy is varied slowly during a 24 hour period. In application of pulsed electromagnetic energy to humans, the magnetic field strength is adjusted to be within 4 to 8 Gauss. The placement of the electrical wiring below the surface of the selected area is adjusted to accommodate these parameters. Further, it is important to note that the spacing of the electric wiring in the above described embodiments may be altered to achieve desired effects.

Although the principles, preferred embodiments and preferred operation of the present invention have been described in detail herein, this is not to be construed as being limited to the particular illustrative forms disclosed. They will thus become apparent to those skilled in the art that various modifications of the preferred embodiments herein can be made without departing from the spirit or scope of the invention as defined by the appended claims.

SYSTEM AND METHOD TO ENHANCE GROWTH AND BIOLOGICAL FUNCTION OF LIVING SYSTEMS WITH PULSED ELECTROMAGNETIC ENERGY

FIELD OF THE INVENTION

The present invention is generally a means to enhance growth and performance of biological systems. More specifically, the present invention is a system and method to enhance physiological performance of organisms through application of pulsed electromagnetic energy.

BACKGROUND OF THE INVENTION

Use of electromagnetic energy to increase physiological performance of organisms has long been attempted. However, many of these techniques have been limited to belts, pads or mats which apply magnetic or electromagnetic energy to the person or other organism. Problems inherent in these techniques include the necessity for the organism to wear the belt or pad, and the necessity for a portable power source in order to generate electromagnetic energy.

Furthermore, these techniques do not effect the environment surrounding the organism, nor do they bring the environment and organism into gentle resonance. Accordingly, there is a demand for an apparatus and method of applying pulsed electromagnetic energy to an organism and its surrounding environment that is without the aforementioned disadvantages.

SUMMARY OF THE INVENTION

The present invention is an apparatus and method of applying pulsed electromagnetic energy to organisms such as humans or other animals, and to the organism's surrounding environment such as grass and other organisms within this environment. Specifically, electrical wiring which emits pulsed electromagnetic energy, is placed under the surface of the area in which the humans or other organisms are situated. This includes putting wiring in proximity to or under the surface of a variety of environments, such as livestock pens, poultry pens, ponds, garden plots, athletic courts, and golf courses. The system and method of the present invention is used in association with various different organisms or living systems such as humans and other animals, as well as plants, for example.

Electromagnetic energy is then pulsed through the electric wiring and diffused throughout the area surrounding the wiring, including the atmosphere above the surface of the selected area.

As the electromagnetic energy diffuses, it is applied to both the plants and animals within the selected area. The application of the pulsed electromagnetic energy brings these organisms into gentle resonance and enhances biological function and genetic expression of these organisms.

Generally, better health, increased appetite and higher consumption of water, are among the positive effects that have been experienced by participating humans.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic diagram of a first preferred embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to an aquatic bio-system.

Fig. 2. is a schematic diagram of a second preferred embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to livestock pens.

Fig. 3 is a schematic diagram of a third preferred embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to a plant bio-system.

Fig. 4. is a schematic diagram of a fourth preferred embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to a basketball court.

Fig. 5 is a schematic diagram of a fifth preferred embodiment of the present invention, illustrating the application of pulsed electromagnetic energy to a golf course.

Fig 6. is a schematic view of an audio system for use with any embodiment of the present invention.
